There is a large forge containing nine hammers operated by compressed air. The heaviest of these hammers weighs 5 tons; the weights of the other eight hammers range from 1 ton to 2 cwt. Here specially tough forgings are made for automobile machinery, shaftings, gears, tool-steel rods, and projectiles. Besides several annealing furnaces already in operation, a large shop is being built for tempering, annealing, and hardening large forged or cast-steel pieces. A second forge is being erected, which is to be fitted up with a 1 ton forging press, one forging hammer of 10 tons weight, and three stampers with falling hammers of 3 tons, 2 tons, and 1 ton respectively.

The steel foundry contains a carpenter's shop for making the patterns, a sand separating plant, a number of moulding machines, the necessary moulding frames, drying and heating furnaces, and a sand blast plant for cleaning the finished castings. The foundry with its present installation will be able to turn out about 10 tons of steel castings daily, but as mentioned above pieces up to 20 tons in weight can be cast.

The following firms have ordered Girod furnaces, and in some cases have been operating them for some time past:—Oehler & Co. (Switzerland); Société John Cockerill (Seraing, Belgium); Stotz & Co. (Stuttgart, Germany); Stahlwerk Becker (Krefeld, Germany); Gutehoffnungshütte (Oberhausen, Germany); Ternitzer Stahlwerk, Schoeller (Ternitz, Austria); Danner & Co. (Judenburg, Austria); Ungarisches Staats-Stahlwerk (Diosgyor, Hungary).

DISCUSSION.

Mr. J. H. Heap said that the present Paper might very well have been considered with Mr. Selby Bigge's Paper, because, taken together, they showed clearly two aspects of an important question—viz., the best means of harnessing waste gas and the best end to which the power when harnessed might be applied. He thought that it was a reproach to them that so little had been done in this country with the electric furnace. They had left the whole of the experimental work to Frenchmen chiefly, secondly to Italians and thirdly to Germans. The condition of affairs in this country, especially in the Middlesbrough district, afforded a splendid opportunity for steel manufacturers to conduct experiments with the electric furnace for manufacturing steel. Taking some of the hydro-electric schemes abroad, the cost per unit was as high, or higher, in most cases than the cost per unit would be by harnessing up the waste gas in the most economical way. He was sorry that a metallurgist of the author's standing had not preferred to give a general summary of the electric furnaces of the present day, in order that manufacturers could have seen what a competent and independent authority had to say on the merits of the various furnaces. He also could not understand the author's logic in approving of the Girod furnace. Taking his conclusions, what one came to was that it was better to take the simplest type of furnace without going into any of the particular improvements of other furnaces. The only point, so far as he could see, in which there was a special feature in the Girod furnace was in the contact pieces, and he was doubtful whether they would last long, even in spite of the arrangement for cooling. He asked the author why it was, if there was the advantage he claimed in having the simplest type of furnace, inventors had spent so much time in devising means for getting over the difficulties of the first designs. The author seemed to take it for granted that there would be a circulation of the contents of the bath. That was not so, however, without some special arrangement. He thought it was strange that it should have been left to Sheffield to be the first to take up the electric furnace. The best place in his opinion was Middlesbrough. His reason for saying that was that, to get the ideal conditions for the electric furnace, one must in the first place have cheap power, and secondly cheap material. The most obvious means of utilising the electric furnace was to take a low-grade steel and refine it, so as to make a high-grade steel. Where could that be done better than in the Middlesbrough district? The ideal electric furnace was that which could use the commonest material and bring it up to the highest grade, employing the cheapest power for the purpose, and he did not know of any district to compare with Middlesbrough for that purpose.

Mr. E. H. Saniter thought that what Mr. Heap said with reference to the very incomplete comparison which was made between the Héroult and Girod furnaces should be remedied. The president had referred on the previous day to incomplete comparisons; this was a glaring instance of an incomplete comparison. What he should like to ask Dr. Borchers was: Did the Girod furnace consume one kilowatt less current to make a ton of steel than the Héroult furnace? That would be very interesting information from such an authority. There was also another point between the furnaces. As far as he could see in the Paper, the Girod furnace, according to Dr. Borchers, was the better type of the two furnaces, because there was only one hole through the roof and one electrode. He did not see any other reason given in the Paper for that, except that the author said something about the resistance of the bath increasing the heat. It was well known that the resistance of the molten metal in the bath played a very small part in the heat generated. The other point was that, comparing the two furnaces, in the Héroult the reaction area was three times as big. He would like the author to say if it was an advantage to have the larger reaction area in the Héroult furnace.

Prof. J. O Arnold said in connection with Sheffield and electric melting furnaces, so far as he, in conjunction with the university authorities had been responsible for this development, the only question they had to consider was the relative melting capabilities of the crucible and the electric furnaces. They did not want a refining machine, but a melting machine, and for that reason they selected the Kjellin furnace. The quality of the material used would remain unchanged, namely, the finest Swedish iron, which produced the finest steel in the world, as handled in Sheffield. The problem they wished to solve at the university was: Is electrically melted steel equal in quality to that melted by the 150-year old crucible process?

Mr. F. W. Harbord said that he had had the opportunity of seeing all the electric furnaces at work with the exception of the Kjellin, and he was surprised that the author should state that the Girod was the simplest. As a matter of fact, a statement like that was rather dangerous. It depended entirely on the particular purpose for which the furnace was required. As compared with the Héroult furnace, the Girod furnace had the advantage with the small sizes, it was true, having only one hole through the roof instead of two; but that did not apply to the larger sizes, where the Girod furnace had to have two electrodes through the roof taking up furnace space, as in the Héroult. The question of electrodes and the circulation of the bath was very small. Nearly all the furnaces claimed special advantages from circulation, and in these days, when one had 200 ton furnaces, one found that one could get quite sufficient circulation without any electrical current, and he did not think in a small furnace of the size which was generally used that circulation was of any importance. It appeared, also, that all the furnaces had practically the same consumption of energy. The amount of refining done in a given time was entirely independent of the electrical part. It was simply a question of having the silicon in the right position to do the work, and both the Girod and Héroult were equally good at refining. Therefore, as the consumption of energy was the same, as also was the product, the question could only be settled by each person taking into consideration his own particular conditions and carefully investigating them. He thought there would be considerable trouble from the bottom electrodes, as when tilting the furnace some of the lime or slag was almost certain to get round the electrodes. He would recommend them, before adopting any kind of electric furnace, to spend two or three weeks at the works, so that they could see in operation for a long period the different types and learn the advantages and disadvantages of each.

Mr. D. F. Campbell made a few remarks about the large electric furnaces in operation in America and compared them with large furnaces of the Girod type. It seemed to him that the statement of simplicity was very true, but he did not think the figures in the Paper in any way justified the opinion that the Girod furnace was the simplest. In the first place, if one compared a 12½-ton furnace with a 15-ton furnace in operation in South Chicago, one found that the 12½-ton furnace of the Girod type had four holes in the roof and 16 electrodes in the bottom. To his mind the holes in the bottom were much more likely to be a source of trouble than the holes in the roof. In electric furnace work it seemed to him to be advisable to stick as far as possible to the open hearth practice and not introduce any novelties. Another point was that the holes in the bottom were liable to become centres from which the dolomite lining would rise, and the steel was liable to get under the layers of dolomite and the bottom would break up. In the furnace in South Chicago the bottom usually lasted about 4,000 to 5,000 heats, with, of course, ordinary settling after each heating. The roof, which was made of silicon brick, usually lasted about 100 to 150 heats. The cost of the roof for a 15-ton furnace was about £12, which worked out at about 2d. per ton for the roof. The point which was particularly brought out in the Paper was the arrangement of the electrodes in the bottom. In practice it was a custom to put a large quantity of lime on to the bottom when smelting, and put the scrap on to that, thus protecting the bottom from the large pieces of scrap. As regards power consumption, at South Chicago, or Worcester, where the 15-ton furnace was in operation, the consumption varied according to the amount of refining necessary. He thought the old idea that electric furnace work depended on cheap water power was a great mistake.

ELECTRIC POWER IN THE IRON AND STEEL INDUSTRIES.

We give below an account of the discussion that took place at the meeting of the Iron and Steel Institute last week, when Mr. Selby Bigge read his Paper on this subject. An abstract of this Paper was given in our last issue:—

Mr. T. Westgarth said that the Paper was really a consideration of what had been done and what could be done in the utilisation of waste heat. In regard to what had been done to utilise waste heat in England, the speaker cited a case at Barrow where a number of gas engines had been installed for providing the blast for the furnaces and to provide electricity for the works. That also furnished a large quantity of surplus gas, which was taken to boilers providing steam for the steel works engines, and immediately resulted in a saving of 1,500 tons of coal per week, equivalent to about £50,000 a year. In another case they had collected waste steam, admitted it to accumulators, and from these had driven low-pressure turbines to generate the electricity for the works, but they had not thought it wise to go so far as to drive their mills and heavier machinery electrically from that source. He supposed the determining factor was that of capital outlay. It was a serious matter in existing works containing good boilers and steam engines to scrap the plant, and it seemed to be a convenient way of effecting economy to use the exhaust steam in that way. In the case of Messrs. Hickman, they had gone a step further and generated sufficient electricity for their requirements, and were driving a very efficient mill by electricity from the same source. In the case of Messrs. Samuelson, where they had no particular use for surplus energy, they sold their exhaust steam to a power company who distributed the energy generated by low-pressure turbines in the supply mains. The speaker thought that was a very economical way of utilising waste heat. There were many ways of using waste heat, and it was to his mind impossible to lay down any general rule. In view of the diagram shown by the author, however, there seemed to be a very strong argument why one should, if possible, use gas engines.

Mr. C. H. Merz thought that in a good many cases the use of exhaust steam turbines or mixed pressure turbines was advocated where the conditions were not properly looked into. Why was there such a passion for mixed pressure turbines? He thought it was because the installation of an exhaust turbine was a happy medium between scrapping old plant and putting in new. With regard to the vacuum mentioned by the author, there were very few cases in this country where such a vacuum was obtained. The expensive part with exhaust and mixed pressure turbines was the condenser, which, however, the manufacturer was not interested in, and therefore he cut it as fine as possible. Regarding the figures for capital cost given by the author, he thought that they were too low for the average conditions, and did not represent the true state of affairs. For example, two 600 kw. turbines could not be completely installed for £9,000. If they were, then they had been installed in existing buildings, or else the condenser equipment had been cut fine. Mr. Bigge put his interest and depreciation as 12 per cent. per annum. The speaker thought it was absurd to talk about writing off plant of that kind in 20 years. The author gave cost of production as 0·2109d. per unit, but considering the latest type of engines and taking repairs into account, the cost of production was nearer 0·5d. per unit, and then there was no allowance for exhaust steam. There were, of course, conditions where the use of exhaust and mixed pressure turbines was justified, viz., such as in the case of Messrs. Samuelson, where they had no use for the whole of their power, and where the very heavy capital expenditure could be made up by using the plant at absolutely constant and continuous load throughout the year. Those were the conditions under which exhaust turbines would prove satisfactory. He wished most emphatically to say, therefore, that managers of iron and steel works should not jump at the conclusion that the exhaust or mixed pressure turbine was the best, because in a good many cases that was not so. He entirely agreed with the author as to the question of high pressure.

Mr. W. C. Mountain said that the whole thing resolved itself into the question as to what the adoption of exhaust steam would cost and what saving would be effected by its adoption. He thought the author was fairly correct in the figure he gave for the cost per unit. The question of rolling mills was one very prominently before them at the present time. He read a Paper some years ago on electric winding, and the conclusion he came to was that it was doubtful whether electric winding would be commercially successful. That remark applied very well to the question of exhaust steam at the present time.

Mr. H. Crowe asked the author whether the 15 per cent. for auxiliary machinery shown in the diagram included blowing engines, or whether they were not considered as auxiliaries, and had been left out of the diagram altogether. The author did not say whether the blowing was done by gas or steam.

Mr. W. J. Larke said, as to the desirability or possibility of using waste gas in blast furnaces, he knew that when considered from the point of view of thermal efficiency it was not an efficient method of using the available gas, but most of the speakers seemed to agree that the one determining factor in the question was not the thermal efficiency, but efficiency measured in £ s. d.—*i.e.*, commercial efficiency. It was quite impossible to make any statement which would be generally applicable, and he agreed with Mr. Merz that every case should be considered on its merits.

Mr. W. Williams said that the way in which he utilised waste gas was by taking gas from certain blast furnaces and using it for raising steam which was sent down to the steel works. A portion of the exhaust steam was then collected and was used for generating the whole of the electric power and driving the blast to work the furnaces. At the present time they were connecting up further plants, and were very satisfied with the results obtained. He thought the keynote was struck when one said that each case should be considered on its merits. Mr. Merz rather doubted the 28½ in. vacuum, but he, the speaker, had found no difficulty in obtaining it.

Mr. J. Mulholland was in a favourable position for collecting data, and thought it would interest them to know that the high power gas engine had now reached a stage at which the following claims could be made: The first cost of a gas engine driven by waste gas was, if not lower, at least as low as that for first-class steam engines using waste gas in boilers. The cost of repair and maintenance for the gas engine was probably lower than for steam plant, with its boiler, condensing plant, feed-water pumps and economiser; and the supervision of a gas engine using blast furnace or coke oven gas was certainly much less and simpler than the steam plant. The superiority of the gas engine as regards heat economy was, he felt justified in saying, an acknowledged fact among engineers.

Mr. Selby Bigge, in reply, said the gas engine had of recent years been enormously improved and simplified. He thought Mr. Merz's remarks about engineers' love of old plant, and their use of the turbine because it was an easy thing to apply, was a reflection on works engineers. Mr. Merz had said that a vacuum of 28½ in. was not often obtained, but Mr. Williams said he had found no difficulty in maintaining such a vacuum, which was a very ordinary one. He had obtained up to 29 in., but 28 in. was the most usual vacuum to work with. He quite agreed with Mr. Merz that the condenser plant must be big enough. Schemes were often spoilt by putting in condensing plant which was too small. With regard to writing off the cost in 20 years, he would be sorry to advocate a scheme with mixed pressure turbines which could not show a return of the capital in three or four years. He thought that his allowance of 12 per cent. for interest and depreciation was a fair figure. He had found the actual cost of production to be invariably below 0·25d. per unit, otherwise it was not worth applying the exhaust turbine. He had obtained the opinions of those who had had actual experience with mixed pressure turbines. Everyone confirmed the figure which he had put forward, by stating that they were producing their electricity at ¼d., or even lower, per unit. Mr. Merz had said that the figure for capital outlay was too low. They were exact figures, however, taken from an actual case. In reply to Mr. Crowe's question as to whether the blowing engine was included in the figure of 13 per cent. for auxiliaries, the engine was included if it were a gas blowing engine, but not otherwise.

Electricity Supply in Vienna.—A recent issue of the "Neue Freie Presse" contains a review of the large electrical enterprises carried out by this municipality during the administration of the late mayor, Dr. Lueger. The original municipal electric power plant was completed by the Austrian Schuckert Works in 1901, at a cost of £1,326,800, but with the additions since made, the total investment has reached £2,520,400. After a bitter struggle, the municipality managed to secure possession on May 1, 1908, of the International Electric Co. for £764,400, and of the Vienna Electric Co. for £212,000. The municipality endeavoured to buy up the private companies as early as 1901, and while it connected its system to dwellings, Dr. Lueger forbade the private company to do the same thing. The city endeavoured to get the police to carry out this prohibition, but this aid being refused, the Mayor made use of the fire department in destroying connections installed by the private companies. In consequence of this arbitrary action and the evident determination of the municipality to control the electricity situation at any cost, the private companies sold their properties. Up to the present time, the city has succeeded in paying all fixed charges on its electrical investment and during the last year had even a surplus of £210,000. This profit, however, has only been obtained by reason of the very high price charged for energy taken by the municipal street railway system, so that it is a case of robbing Peter to pay Paul. Moreover, the original estimates for the cost of the completed system were exceeded by £900,000, and the consumers have had no benefit from municipal ownership through any reduction in the price of electrical energy. The ambition of the municipality to have a complete monopoly of electricity supply has not yet been achieved, as there is still a private company known as the Austrian General Electric Co. which carries on a large business.

The Rates for Subscriptions to "THE ELECTRICIAN" are as under :—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New Volumes of "THE ELECTRICIAN" *commence in April and October.*
(This charge includes all Supplements.)
Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15c. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. B. Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-eighth issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for April 29.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

In consequence of Friday, May 20th, having been appointed a day of National Mourning in connection with the obsequies of His late revered Majesty King Edward VII., THE ELECTRICIAN will be published on Thursday morning, May 19th, instead of Friday morning, May 20th.

Contributions, Correspondence, Advertisements and other matters intended for next week's issue should therefore reach us not later than first post Wednesday morning, May 18th.

ECONOMY IN THE BOILER HOUSE.

In the earlier days of electric power stations every attention was given to the electrical side in regard to efficiency, but comparatively little consideration was bestowed upon the operation of the steam-raising portion of the plant. Perhaps this was a little natural, for the average electrical engineer had been reared with electrical ideas as his main principles in life. It was comparatively easy to know how one stood in regard to electrical losses and losses in generation, and they were more easily fixed once for all than in the remainder of the plant, so that the boiler house received the smaller share of attention. This attitude towards steam generation has been somewhat general, as is rendered evident by a consideration of water softening. At one time it was quite a common practice to use boiler fluid and thus to use the boiler as a kind of water softener, generally with very undesirable results; or, not unfrequently, no attempt at softening of any kind was made. Fortunately, it has been realised of recent years that water softening should take place not in the boiler but outside it,

Digitized by Google

and that any outlay on a water softener is very soon repaid by the very much smaller consumption of coal and the better condition of the boilers. In that respect present practice is more enlightened than it used to be.

It is, however, also necessary to remember that the heating side of the tubes or boiler surface is in many respects as important as the water side. Those engineers who have worked on refuse destructors in conjunction with steam-raising plant know very well the marked effect produced by dust in diminishing the steam-raising power of a boiler. Dust is difficult to deal with, because it lies somewhat thickly and very soon collects, thus preventing the transmission of heat from the flue gases. What is true of dust is also true, though to a less extent, of soot, for this is by no means a good conductor of heat; and although the soot and pitchy matter take a longer time to collect than dust, their effect is certain to be shown in a reduced evaporative capacity of the boiler. So far this effect has not attracted very much attention on the part of engineers, but we are glad to see that Mr. P. J. PRINGLE, electrical engineer to the Burton-upon-Trent Corporation, has now taken the matter up with very considerable success.

Mr. PRINGLE'S attention was first directed to the subject by tests on the flue gases and by attempts to get a larger percentage of CO_2. In overhauling boilers it is usual to brush down the outer surfaces with a hard brush. This frees the surface from any serious collection of soot or soft deposit, but it does not go far enough. This point has, no doubt, been appreciated by the makers of economisers, in which scrapers are continually in motion. A somewhat similar method of cleaning the soot from the boiler and tubes has now been adopted by Mr. PRINGLE, who periodically scrapes them down with hard steel scrapers so as to get as near the metal surface as possible. The deposit was found to be of a hard, ashy nature, varying in thickness from $\frac{1}{32}$ in. to $\frac{1}{8}$ in., but becoming more tough and pitchy towards the cooler parts of the flue. If the usual sooty deposit is added to this there is a total thickness of as much as $\frac{3}{8}$ in. in some parts.

The scraping is carried out at periods of two months, or after about six or seven weeks' service, and at a cost of about 15s. per boiler. The result of this treatment has been a very marked increase in the efficiency of the boilers. Perhaps this result is shown most simply by remarking that during the past year there has been a saving of 14·8 per cent. in the total amount of fuel used, compared with that in the previous year, notwithstanding that the output has been slightly greater during the 12 months ended March 31st last. The saving, however, is considerably larger than is indicated by this figure, since greater use is being made of poorer grades of fuel. In fact, the saving is more clearly indicated by stating that the coal bill for the period in question actually showed a reduction of 27·6 per cent. It is interesting to notice that out of about 280 undertakings for which statistics are available there are only 30 having a lower fuel cost per unit than that obtained at Burton-upon-Trent. Considering that the undertaking is not large, and that the yearly load factor is only about 20 per cent., this performance must be considered as extremely satisfactory, and we hope that other engineers will take the matter up and pursue the subject so ably tackled by Mr. PRINGLE.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Leçons d'Electrotechnique Générale. By P. JANET. 3rd edition. Vol. II. (Paris: Gauthier-Villars.) Pp. iv. + 325. Fr. 11.

The second volume of the third edition of this work has followed quickly upon the first, which was reviewed in these columns during the early part of the year. The book before us is in every way a companion volume to the first, which dealt with general principles and continuous currents. The treatment of the subjects is thus not at all of a descriptive nature, but is rather a mathematical study of the properties of alternating currents and alternating current apparatus. This volume then will again appeal to the advanced rather than to the elementary student.

The book consists of eight chapters, the first of which is devoted to a general study of harmonic functions, vector diagrams being carefully treated. The second chapter deals very fully with sinusoidal alternating currents, and the third with non-sinusoidal. Fourier's series and its applications are gone into at considerable length, and a useful table is given for the analysis of wave forms containing odd harmonics up to the seventeenth order. The fourth chapter, on alternators, is chiefly devoted to the theory of windings, and to the wave shape. The effect of the distribution of the armature conductors, and the influence of the armature teeth upon the resulting wave shape are both discussed at some length. The various devices adopted to eliminate harmonics are briefly mentioned. A short chapter follows on choking coils, and then a fairly long chapter on the theory of transformers. The theory of the transformer is attacked from both the mathematical and graphical points of view, the circle diagram being very fully treated. The final chapters are devoted to the characteristics of alternators with constant reactance, and the armature reaction of alternators with variable reactance. Blondel's and Potier's methods are both given at considerable length.

The treatment of the subject matter is very uniform and very thorough, and so far as we can see the author has omitted no point likely to be of theoretical interest. Extensive bibliographies follow the chapters on transformers and alternators, and these should be very valuable to the student who has the standard French technical papers at his service.

The parallel running of alternators, the compounding of alternators, converters, alternating-current motors and transmission of power are dealt with in the third volume, which has not yet been published in its third edition. When the series of these three books is completed it will form a very useful text book for the advanced student who has a liking for mathematics. The intending purchaser should remember that the books are supplied in thin paper covers, so that he will find it necessary to have them re-bound. A. E. CLAYTON.

Die Vektoranalysis und ihre Anwendung in der Theoretischen Physik. By Dr. W. v. IGNATOWSKY. Vol. VI. of "Mathematisch-Physikalische Schriften für Ingenieure und Studierende." Edited by E. Johnke. (Leipzig: B. G. Teubner.) Pp. vi. + 102. M 3.

The extensive use of vector analysis in all branches of mathematical physics, and more particularly in electromagnetism, has created a demand for a good introductory treatise on the subject. Such a treatise can only be written by a thoroughly competent mathematician, as it is essential that the reasoning should be rigorous, and that the limitations of the theorems should be accurately stated. Judging by the first volume of this book we think that it meets the demand.

The author not only gives a thorough discussion of the differential and integral operators used in vector analysis, but he also gives geometrical illustrations of their meaning. We were surprised that no reference is made to Heaviside's excellent work on this subject. Many physicists in this country believe that the word "curl," which mathematicians use for the process by which current is derived from magnetic force, is

Digitized by Google

due to Heaviside. As a matter of fact he popularised it, but Maxwell was the first to propose it.

In a footnote the author tells us that "curl" is an English word, but he leaves the reader to decide whether it is derived from a "lock of hair" or a "cork-screw."

This volume is exclusively mathematical, and the rigorous reasoning of the mathematician is apparent on every page. Although the subject is a difficult one, the absence of superfluous physical illustrations which cumber many other books on this subject makes progress rapid. We can cordially recommend this book to all physicists and engineers whose knowledge of mathematics is sound and extensive. A. R.

Funktionentafeln mit Formeln und Kurven. By Dr. Eugen Jahnke and Fritz Emde. Vol. V. of "Mathematische-Physikalische Schriften fur Ingenieure und Studierende." Edited by E. Jahnke. (Leipzig: B. G. Teubner.) Pp. xii + 174. M.6.

To physicists and engineers having a slight knowledge of Bessel's, elliptic, and hyperbolic functions we can heartily recommend this book. Many exact solutions of important practical problems have been obtained in terms of these functions, and this book enables the mathematical engineer to utilise such solutions.

The practical man frequently rails at the mathematician for using a notation with which he is unfamiliar. He may be familiar, for instance, with Legendre's notation for elliptic integrals and would welcome a formula containing these functions. The mathematician, however, generally prefers to give his results in Gudermann's, Jacobi's or Thomæ's notation. We have even come across a formula for the mutual inductance between two coils in which the functions were given in Weierstrass's notation. We have known students who have attempted to wade through mathematical treatises which were hopelessly beyond their depth in order to find out how such functions are computed. If lucky, they may come across some weird series which will enable them to compute the function, possibly after great labour. To men of this type this volume will be invaluable, for not only are tables of the numerical values of the functions given, but also the various definitions, notations and formulæ for the functions.

From personal experience the reviewer can say that the possession of this book ten years ago would have saved him weeks of hard arithmetical labour. He is looking forward to using it frequently in the future. The only errors he has noticed are those in the tables for the ber and bei functions. The corrections for these tables will be found in Papers by Dr. A. Russell and Mr. H. Savidge read recently before the Physical Society of London. A. R.

PLATINUM RESISTANCE THERMOMETRY AT HIGH TEMPERATURES.

In a recent issue of the "Bulletin of the Bureau of Standards" particulars are given of an investigation carried out by C. W. Waidner and G. K. Burgess to determine the advantages and limitations of platinum resistance thermometers at high temperatures, especially with reference to reproducibility of scale, method of calibration, formulæ best expressing the relation between resistance and temperature, effect of impurities in the platinum wire, changes due to high temperatures, and the most satisfactory method of construction and use. The reproducibility of high temperatures by the melting or freezing points of metals obtained from different sources and furnished as chemically pure was also studied.

Eleven resistance thermometers were used, made of wire of varying degrees of purity and of various sizes from 0·1 mm. to 0·6 mm. diameter, and with resistances, R_0, ranging from 0·11 ohm to 21·5 ohms. Two of these thermometers were made of pure palladium wire 0·3 mm. diameter, while the other nine were of platinum. Three types of thermometer were used, which may be briefly designated as compensated lead type, potential terminal type, combined compensated lead and potential terminal type. In the compensated lead type, due to Callendar, two fairly large platinum leads (preferably over 0·6 mm. diameter), as nearly identical as possible with the leads to the coil, run down the stem of the thermometer, and are connected at their lower ends. When these leads are put into the arm of the Wheatstone bridge adjacent to the arm in which the thermometer coil is inserted the thermometer is compensated for variations in temperature of the leads to the coil, due to variable depth of immersion. To compensate for the effects of heat conduction from the coil along the heavier platinum leads, the ends of the compensating leads are joined by a short length of fine platinum wire of the same size as the wire of which the coil is made. In thermometers of the potential terminal type two leads are fused to each end of the coil. In this type of thermometer both the current and potential leads may obviously be made of much smaller wire than for the compensating lead type. The method of using this thermometer consists in comparing the P.D. at the terminals of the coil with the P.D. at the terminals of a known resistance carrying the same current. In thermometers of the combined compensated lead and potential terminal type the current leads should be made of fairly large wire to secure better compensation.

The investigations are described in detail by the authors, and the following general conclusions are reached.

Temperature Scales.—Temperatures defined by the resistance thermometer of pure platinum calibrated by Callendar's formulæ at 0 deg., 100 deg. and 444·70 deg. (the boiling point of sulphur), agree with temperatures on the generally accepted gas scale in the range 0° C. to 1,100° C., to within the degree of reproducibility of the latter. Thermometers made of impure platinum, and calibrated in the same way, do not define the same temperature scale as that of pure platinum, the divergence increasing with the impurity of the metal. If thermometers of impure platinum are calibrated at a fourth temperature, such as the silver freezing point, and the difference coefficient of the Callendar formula is written $\delta = a + bt$, then the scale so defined by these thermometers is brought into very close agreement with that of the thermometer of pure platinum.

The Dickson formula $(R + a)^2 = p(t + b)$ is not applicable to either platinum or palladium thermometers at high temperatures. The palladium thermometer, calibrated by the Callendar method, gives temperatures agreeing to 1 deg. with the scale of the platinum thermometer up to 600 deg. It requires a fourth degree equation to express its resistance temperature relation from 0 deg. to 1,100 deg.

The table below of freezing points represents the scale of the resistance thermometer of pure platinum as determined from this investigation, using only the purest metals.

Thermocouples of *Pt*, 90 *Pt*–10 *Rh* and *Pt*, 90 *Pt*–10*Ir*, calibrated at three temperatures in terms of the formula $E = a + bt + ct^2$, define a temperature scale in the interval 200 deg. to 1,100 deg., which is in agreement with the platinum resistance scale at intermediate temperatures to within 0°·3.

Behaviour of Platinum Thermometers.—When used at high temperatures the constants of platinum thermometers undergo gradual changes, which necessitate frequent recalibration in work of high precision. The use of thermocouples for work above the freezing point of silver is therefore much less laborious. These changes in thermometric constants are greatly reduced, but not completely eliminated, by annealing the thermometers for at least several hours at a temperature higher than that at which they are subsequently to be used. For thermometers of pure platinum, the changes in their constants after the thermometers have been annealed, are very much less than for those of impure platinum; thus, R_0 changes only by a few tenths of a degree for pure platinum, but by several degrees for impure. These changes are least for pure platinum wires of large diameter and suspended free from strains. For such thermometers, made of wire 0·6 mm. in diameter, R_0 changed by only a few tenths of a degree after repeated and continued heatings at 1,200 deg. to 1,300 deg.

For impure platinum wire the effect of high temperatures is to decrease R_0 and to increase the fundamental coefficient, ϵ, that is,

Metal.....	Sn.	Cd.	Pb.	Zn.	Sb.	Al.	Ag_2Cu_2	Ag.	Cu.	Cu_2O
Freezing point	231°·92	321°·01	327°·43	419°·37	630°·71	658°·0	779°·20	960°·9	1083°·0	1063°·2
Average deviation for purest metal	0·02	0·02	0·10	0·02	0·30	0·5	0·25	0·20	0·5	0·3
Reproducibility factor	0·06	0·26	0·10	0·06	2·3	1·2	..	..	1·0	..

The average deviation of a single observation is a measure of the precision attained when two or more thermometers were used in a single metal sample. The reproducibility factor is the average deviation of the metals, designated as C.P. or better, from their mean freezing point.

Digitized by Google

the effect is as if the wire became purer, possibly because of the evaporation of impurities, for example, iridium. If the platinum is pure, the slight changes indicate a contamination of the wire and the effect of strains, as is evidenced by decrease in c and the increase in R_0. The total change observed is a resultant of the effects of strains, of annealing, and of contamination and purification. In the use to which these thermometers were subjected in this investigation, the changes in the value of δ were almost within the limits of experimental error. For impure platinum there is evidence of a slight decrease in this constant.

Calibration Temperatures.—The freezing points of the pure metals are the most satisfactory calibration temperatures, being superior to boiling points in constancy, ease of manipulation, and reproducibility. Unless a very slow rate of heating is used, melting points are less satisfactorily fixed and apparently slightly higher than freezing points.

The temperature of the separation of the silver-copper eutectic is an entirely satisfactory fixed point at 779°·2, when the alloy is of the eutectic composition, or about 72Ag–28Cu. The eutectic point of copper-cuprous oxide is also a satisfactory calibration temperature at 1063°·2, when proper experimental precautions are taken to maintain the eutectic composition.

Boiling Point of Sulphur.—The temperature defined by the vapour of sulphur boiling at known pressure and under carefully specified conditions is a most satisfactory fixed point, reproducible to a few hundredths of a degree. These conditions are briefly: (*a*) Sulphur to be boiled in a glass tube 4 cm. to 5 cm. diameter and of sufficient length to insure ample depth of immersion in the vapour (tube about 40 cm. satisfactory). (*b*) Sufficient depth of liquid sulphur to avoid superheating, a criterion for the above conditions is absence of change in the observed resistance when the thermometer with its attached radiation shield is moved some centimetres up and down the tube). (*c*) Surrounding the coil of the thermometer with a suitable radiation shield to avoid the cooling effects of the condensed sulphur running down the stem of the thermometer and of radiation to the cooler parts of the apparatus.

Both gas and electrically heated sulphur boiling point tubes were used; the former gave a temperature 0°·03 or 0°·04 higher than the latter.

The determinations of the sulphur boiling point by different observers is discussed at length. The determinations of these observers are in satisfactory agreement, the values found ranging, with one exception, from 444°·5 to 444°·7. The bearing of some recent work with the gas thermometer on the value of the sulphur boiling point is considered, which shows that the above value may be too high. The evidence, however, is not sufficient as yet to warrant any change in the generally accepted and widely used value of the sulphur boiling point.

S. G. BROWN'S TELEPHONE RELAY.

The Paper read by Mr. S. G. Brown last week at the meet- of the Institution of Electrical Engineers, and of which we gave an abstract in our last issue, aroused great interest. We give below an account of the remarks of those speakers who contributed to the discussion;—

Mr. J. E. Taylor said that on the first occasion when he saw Mr. Brown's relay he was not quite so much impressed with the instrument as he had expected. It certainly did magnify sounds very considerably, but it appeared to be a little unstable in its action. However, at a later date his views were considerably modified. He found that, provided one could get suitable points and a good instrument to start with, it would maintain its adjustment and keep its magnifying properties without a great deal of variation, and he could testify to the fact that it was capable of picking up wireless telegraph signals which were entirely inaudible on the ordinary telephone receiver. Signals which were just audible were very considerably magnified, probably something like 20 times, as the author had stated. He believed that the reason why the instrument did not behave so well on the first occasion as on the second was that the upper contact point had got slightly flattened. He asked the author whether it was necessary that extreme care should be paid to keeping the point of the upper contact as perfect as possible in order that the magnifying power of the instrument should be properly maintained, and its reliability and constancy assured. Regarding the author's new form of microphone, he was much struck with the volume of sound which it was possible to obtain at the end of an artificial line representing 60 miles of standard cable. When it was considered that 43 to 45 miles of standard cable was the utmost length of that type of cable which could be reliably spoken through using ordinary telephone apparatus, and that through the 60 miles of cable which Mr. Brown employed he had heard the speech quite plainly, one would appreciate that the instrument was capable of giving considerably better results than any carbon microphone, at any rate under laboratory conditions. It was a little early to predict what utility there might be for the new appliances, but he thought the instruments were extremely interesting and suggestive of future progress.

Mr. B. Davies referred to the work carried out by Sir Oliver Lodge on this subject some 10 or 11 years ago. Sir Oliver worked with carbon, which at that time was about the only material one could think of that would act successfully, and carbon, as a matter of fact, was in its microphonic qualities excellent. If one traced the characteristic curve of carbon—*i.e.*, the curve representing the relation between the current and the pressure exerted on the carbon points—it would be found to be excellent in itself, but, curiously enough, it was difficult to obtain. An experiment was performed some 10 years ago by Sir Oliver to show that, if a carbon point were fixed to an arm of a balance like that of the Kelvin balance—and underneath another carbon fixed to the supports, whilst at the other end one had two coils, one fixed to the arm and the other to the supports, it was possible in that way to vary the pressure, however light, exerted between the carbon points without disturbing the system and one could draw the curve very nicely. If, however, the pressure were suddenly released, the chances were that the original curve could not be regained. He asked whether the author had obtained such a curve for his relay. Sir Oliver's primary object was to produce a monotone instrument. In this he was signally successful, the instrument giving remarkable results. The difficulty with the carbon when used for the voice was that although the speech was moderately good for one instrument, there was a loss in articulation on working in tandem which was rather serious. With regard to two relays in series, he asked the author what results he had obtained in that way. Ten years ago it was thought that a great deal of the loss was due to the carbon itself. The power was frittered away, due to the want of elasticity. The hardness of materials was certainly a most important point in the author's relay. He asked the author if he had tried the relay on a really long line. There was no getting over the loss in the line itself—the loss of articulation due to distortion. As they knew that the author's instrument would really magnify well, and, he supposed, articulate well also, it might be possible to work on distortionless lines—*i.e.*, lines supplied with proper leakances in order to get the maximum articulation. They were far from that at the present time. He then showed one of Sir Oliver Lodge's instruments. The whole instrument was suspended by means of springs in order to suppress the effects of extraneous noises and mechanical tremors.

Prof. J. Perry asked Mr. Davies whether the instrument was for the transmission of one musical note.

Mr. Davies: Yes. Sir Oliver's experiments on speech were made with instruments that were aperiodic, but owing to the loss in articulation they were not so successful as the monotone experiments.

Dr. Voysey, although he could not pretend to understand the technical details of the relay, appreciated its application to the purpose of an electrical stethoscope. He had tested such a stethoscope in the out-patients' department of a hospital and over the telephone and had been much impressed by it. What might be the ultimate practical value of the instrument it was yet difficult to predict. It might enable us to demonstrate that what were now regarded as simple sounds were in reality compound, and it might be the means of splitting them up into their constituents. It might enable us to determine the exact relationship in time between the occurrence of the heart contraction and the heart sounds. Clinically, it might render it possible to detect sounds in the body which at present we might suspect to exist, but had been unable to hear owing to the fact that our capacity had been limited to the sensitiveness of the ear itself. For instance, we might hear a sound caused by the friction of gall stones in the gall bladder, of calculi in the kidney, or of the passage stream along an aorta roughened disease. It would be very difficult to damp down or exclude extraneous sounds or to tune the instrument at will to different sound wave-lengths, but Mr. Brown had already solved so many difficult problems it would be a bold man who would deny him this success.

Mr. J. F. Kingsbury said he would like to fill in part of the gap from the author's opening statement to where he reached his own relay. He did not think the author did complete justice to the workers in the intervening period. In 1905 there was a patent No. 11,605 standing in his (Mr. Kingsbury's) name as representative of the owners, which represented a repeater known as the Shreeve repeater. This was unquestionably a practical telephone relay. He spoke through it some five years ago himself, and it had been continued in every day commercial use. He thought, therefore, the credit should be given to Mr. Shreeve for having solved the practical difficulty of the telephonic relay. There had been a demand for a telephone relay for a long time. The first patent for a repeater was taken out by Gilliland in 1881. He said that there should be a demand for a repeater for telephones as there had been a demand for repeaters in telegraphs. That was so, but it was true that the demand had not been filled in such a way that it could be regarded as a satisfactory method for general adoption. The repeater which had been employed had not been used largely. It was subject to drawbacks in the shape of adjustments, which experience only would overcome. He expressed his appreciation of Mr. Brown's relay, but said it must be realised that there were still difficulties to be overcome. A relay that talked only one way was not a practical system. As to the construction, Mr. Brown had, undoubtedly, gone on new lines, but he (Mr. Kingsbury) sometimes wondered in looking over Mr. Brown's description whether the two metallic contacts were not somewhat akin to the Berliner microphone. Of course, the automatic adjustment arrangement was entirely different from anything that Berliner ever thought about. The transmitter also was very satisfactory, but he wondered whether the author had not been somewhat misled by the statements which he quoted from authorities in

Digitized by Google

regard to carbon. Carbon had been, whether the subject of a patent or not, invariably used for telephonic purposes. That it was the best that had come before the experimenters he took for granted from its continual use.

Mr. B. S. COHEN emphasised the point mentioned by Mr. Kingsbury as to the action of the transmitter in the relay. Some tests had been carried out in the National Telephone Co.'s laboratory on both the telephone relay and the metallic granule transmitter. The results obtained with the relay were not quite so good as those obtained by the author, but that was probably due to want of experience in adjusting the apparatus, although considerable time was spent in preliminary adjustment. With one relay placed at the centre of a line, the improvement due to the relay was equivalent to 19 miles of standard line, judging purely by volume. Articulation tests were then carried out on 44 miles of standard cable with a relay in circuit and on 25 miles without the relay. It was found that the number of words missed was 55 per cent. more with the relay than without, so that the articulation with equal volume was about 55 per cent. worse with the relay. The lengths of cable were then readjusted to give equal audibility, which, of course, included both volume and articulation. The result was that the relay gave a net improvement of 8 miles of standard line. Of course, that appeared to be very little, but it had to be borne in mind that 8 miles of standard line would represent about 250 miles of trunk line. It had also to be remembered that the improvement would be considerably reduced when double repeaters working both ways were used. The Shreeve repeater referred to by Mr. Kingsbury was in use on several long lines in the United States by the American Telegraph & Telephone Co. It was generally used in series at the middle of the line whose total length was not less than about the equivalent of 12 miles of standard line. With shorter lengths some trouble was experienced. To get the best results the repeater had to be at the exact centre of the line, so that the line on each side of it balanced. More than one repeater could be inserted in a line; for example, on one of the long lines running from Boston, 1,500 miles long, three repeaters were worked in series, and the net improvement was 18 miles of standard line. The results obtained with the author's metallic transmitter were decidedly encouraging. Under favourable conditions the transmitter gave an improvement for the commercial common battery transmitter of about 10 standard miles and the articulation was good. It would be realised from that figure that the transmitter was quite promising provided that the commercial product could be turned out in bulk with the same efficiency. It was unfortunate that the author had been unable to design an instrument of that type capable of working on the standard common battery circuit. That limited its usefulness. It was to be hoped that the author would be able to overcome that difficulty. Undoubtedly, a considerable amount of work was still necessary to make both the relay and the transmitter of value for practical telephonic purposes.

Mr. A. C. BOOTH had experimented with Mr. Brown's relay during the last three months. It was first tried for intensifying the received signals at radio-telegraph stations, and gave very promising results, magnifying the received signals from 4 to 12 times. It had also been tried for working as a repeater for telephone purposes—*i.e.*, it was placed in the middle of an artificial telephone line of 68 miles of standard cable—with the result that the speech at the end of this line was very little inferior to that over 34 miles of standard cable without the relay. When the line was put direct through 68 miles speech was practically nil. As a further test the relay was placed half way along 108 miles of standard cable, and although conversation was out of the question, one could clearly distinguish that speech was being transmitted, whereas without the instrument the 108 miles of cable were absolutely silent. As regards actual trunk line working, they had not yet more than commenced that stage of the experiments. Having dealt with the practical advantages of the instrument, he next referred to its weaknesses. In the first place, although the adjustment was simple, it had been his experience that the instrument took time to settle down to its work; sometimes more than an hour had been spent continually regulating before good results could be obtained (that, of course, might be due to insufficient experience). Secondly, in regard to radio-telegraphy, the detectors were as a rule absolutely silent except when signals were being received, whereas the relay gave a very slight, but appreciable, noise, due to its microphonic qualities. This noise was not the whistling or humming that arose with a too sensitive adjustment, and although so small it seemed to have a disturbing effect on the operators, who, it must be remembered, had to wear headgear telephones for several consecutive hours daily. As regard trunk telephone circuits, it was obvious that such a very sensitive instrument would magnify any defects or disturbances that might exist upon a line, and as a rule the longer the line the greater the number of minor defects, and it was on the long lines that such an instrument would be used. Then as regards the to and fro conversation, the switching necessary for this was certainly a disadvantage, and if the public were paying 10s. for three minutes he was afraid the switching operations would appear to occupy more time than the conversation. The instrument had not been in use sufficiently long to give any idea as to its stability under continuous working conditions, and he fancied that some slight re-regulation would occasionally be necessary. This, of course, was another weakness, as the telephone public expected perfect speech with no lost time, quite irrespective of the length of line employed. In conclusion, he considered that Mr. Brown's invention marked a very long stride in the direction of that most desirable object, a perfect telephone repeater.

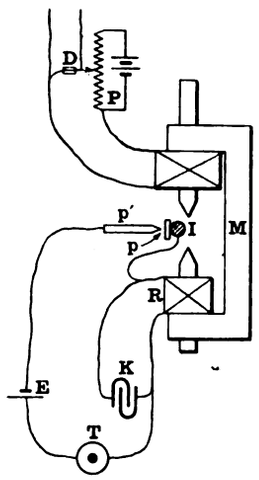
Dr. W. H. ECCLES confined his remarks to the application of the telephone relay to wireless telegraphy. A disadvantage about relays was that they would magnify atmospheric and other disturbances as well as the sounds received from the station. Last year he had been working on one which tended to be acoustically selective; in fact, if one took Mr. Brown's relay and put instead of a reed an iron wire and stretched the wire so that its natural frequency was equal to that of the singing notes used in modern wireless telegraphy, regulating the gap in the same way as the author did, one then had the relay which he, Dr. Eccles, had brought with him to that meeting. This relay (*see* diagram herewith) was based on almost the same principle as that of Mr. Brown, except that it was selective, having a free wire instead of a damped reed. One difficulty he found with this selective form was that it did not select perfectly. The fact was that when one put a singing wire very near to a point in oil one got such considerable damping that the possibility of getting perfect selectiveness was much reduced. He thought this was one of the chief objections against good selectivity. He usually worked on the Clifden signals as heard in London up till last December. They were very faint, and although he could get them magnified two or three times, he found that one of the vices of the instrument was that it quickly started singing on its own account and would go on for five or ten minutes. p' and I (*see* diagram) were on one support, M on another. The contact pp' was made very lightly at a distance from the poles of M, and then the two supports were moved towards one another till the contact pp' opened very slightly. If x was the thickness of the air film or oil film at the contact, $x\rho$ its electrical resistance, R the resistance of the regulating coil, a the film thickness in the undisturbed position of the wire, the restoring force on the wire was given by

$$F \propto x - a - \left(\frac{b}{R + x\rho + c}\right)^2,$$

where b and c were constants governed by the E.M.F.s at E and P. Thus

$$\frac{dF}{dx} \propto 1 + 2b\rho \frac{\sqrt{x-a}}{(R+x\rho)^2}$$

in the equilibrium position—which was thus seen to be remarkably stable. At the beginning of the Paper the author referred to the theory of gases and the passage of ions across a very narrow air-gap, and then proceeded later in the Paper to put oil in the gap to get rid of the air. He (Dr. Eccles) agreed with Mr. Cohen's supposition that a main point in the explanation of the relay was that the resistance of the thin film of oil at the contact (nothing was a perfect insulator) altered with variations of the thickness. Taking that, one could get a good idea of the size of the gap that was maintained by the automatic regulation devised by Mr. Brown. Some years ago Dr. P. E. Shaw measured by the method of electrical touch that the minimum audible sound involved a diaphragm movement of 0·7 milli-micron, or 0·028 of a millionth of 1 in. Further, by the same method Dr. Shaw measured displacements as small as 0·016 millionth. This measurement proved, by the way, the possibility of electrically relaying inaudible motions. Taking this change of thickness as causing about one-half of 1 per cent. variation of the film resistance, it was found that the conduction space in Mr. Brown's instrument must be not greater than, say, about 4-millionth inch, a distance including about 100 molecules. Now, the half wave-length of blue light (the limit of microscopic vision) was about 6-millionth inch. From these figures one could appreciate the beauty of the automatic adjustment developed to perfection by Mr. Brown. He, the speaker, as also another experimenter with the same crude instrument here shown, had not achieved success, and, therefore, the more warmly congratulated Mr. Brown on his wonderful instrument.



D. Detector connected in a receiving circuit. P. Potential divider. M. Soft iron magnet energised by steady current through detector. I. Cross section of iron wire stretched to acoustic resonance with signals. p, p'. Platinum contacts. K. Condenser. T. Telephone. E. Voltaic cell. R. Regulating Coil.

Mr. E. H. RAYNER asked whether it was necessary to have the point of negative polarity, or could it be positive?

Mr. BROWN said it was advisable to have it negative, as it worked better. The reason was the same as that for which the small carbon in an arc lamp was made negative. The ions flowed better to a small point.

Mr. RAYNER, continuing, said that the author mentioned the use of invar for the reed only. Was that for magnetic or mechanical purposes? Would it be an improvement to use invar more extensively to keep the dimensions constant and to avoid temperature changes?

Mr. BROWN said that invar was used for the purpose of keeping the temperature constant and to keep the reed from warping, as it was likely to buckle under the effect of temperature. Of course, it would be better if the whole of the instrument was made of invar, but they had not got as far as that yet.

Mr. D. H. KENNEDY said that with Mr. Booth he compared the effect of having the telephone relay in the middle of 68 miles of cable as against speaking over a cable 34 miles long without the relay. The former gave louder results, but the second case gave better articulation. There was a little difference in the quality, but it was not great; in fact, not more than one was accustomed to find in changing from one transmitter to another. Subsequently, he listened to the same voice speaking through 108 miles with the relay at the centre, and he was able to follow what was being said. When the relay was cut out the cable was quite dead. On the question of adjustment, when making the above trials he put the

Digitized by Google

instrument slightly out of adjustment, but he found no difficulty in getting it back into adjustment. He was struck with the wonderful way in which the milliampere-meter needle followed the movement of his hand on the adjusting screw. He had also heard at London the effect of speaking from Glasgow with the relay in circuit; there was greater audibility, but, unfortunately, there was also a great increase in the extraneous noises. That, of course, was one of the lines for further investigation by Mr. Brown, also the question of reversibility. He did not know whether the author had considered the possibility of using the instrument in the same way as the telegraph local sounder relay was employed—that is, to have a relay at each of two stations with a switch in the receiver case to alter the connections so as to cut in the relay when listening, and the transmitter when speaking. He also asked had any oscillograph records been taken. On the question of carbon, he thought it had been definitely shown that carbon did not change its resistance under pressure and that the microphone phenomenon was one which depended upon greater or less intimacy of contact between the particles. Finally, he thought that the instrument would really increase the distance over which telephone speech would be possible and it was, therefore, a very definite and noteworthy achievement.

Mr. W. M. MORDEY read a passage from the discussion on a Paper on "A New Telephone Transmitter," by John Munro, in March, 1883. Prof. Hughes, the inventor of the microphone, in speaking on the question of carbons, said "The point brought out by Mr. Munro is one which I tried to point out in my first Paper, viz., that by means of metallic contacts we could transmit speech just as well as with carbon by employing a number of contacts." Again, Mr. Munro, in the Paper, stated: "For the carbon microphone is now shown to be only *one* illustration of Prof. Hughes' wide discovery that a delicate contact between any two *conductors* has the property of transmitting sounds. The Reis original transmitter, with a delicate platinum joint, is seen to have been another illustration of the same phenomenon. Prof. Silvanus Thompson has recently presented proof that Reis did send articulate words by his transmitter; and I believe there is no doubt he did. I have myself heard by telephone, and understood, single words spoken direct to the platinum contact of a Reis transmitter. Reis, then, employed a platinum microphone, without knowing it, as early as 1861; and Edison used a carbon microphone, without knowing it, in 1877. The discovery by Prof. Hughes in 1878 threw a flood of light on both inventions." He (Mr. Mordey) did not bring those two statements up in order to lessen the credit due to the author, but merely to remove any impression that there was anything new about using metal itself for telephonic purposes.

Prof. J. PERRY said that the theory of the instrument was exceedingly simple, and that he would communicate it for publication in the "Journal."

The CHAIRMAN (Mr. S. Evershed) drew attention to the fact that the author's instrument was not, strictly speaking, a relay. No complete telephone relay had ever been invented, nor had any approach to one been made. In the case of telegraphy we used an instrument which enabled the feeble currents which arrived at the far end of the line to be restarted, or rather new currents were started, precisely the same in value, number, frequency and duration as those transmitted from the original station. Such an instrument might, he thought, legitimately be called a relay; but when one came to telephony the problem was totally different. In telephonic speech currents, in the first place one had a large number of waves of different frequencies and amplitudes. They all started out in the right phase relation, amplitude and frequency for articulate speech, but they arrived at the far end of the line with their amplitudes all out of proportion and their phase relations all wrong. A true telephonic relay must therefore not only restore the original amplitudes but also restore the waves to their original shape and phase relation. He was not at all sure that it was not an impossible problem to solve. In conclusion, the speaker was very much struck with the possibilities of Mr. Brown's repeater for wireless telegraphy.

Mr. S. G. BROWN reserved his reply to the discussion for the "Journal."

CORRESPONDENCE.

EFFICIENCY OF SHORT SPARK METHODS OF GENERATING ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having just read with unpraiseworthy delay the controversy contained in recent numbers of THE ELECTRICIAN regarding the efficiency of wireless telegraph plants, I think it may be useful to point out how a simple test can be effected.

On switching the aerial off and on, different R.M.S. currents i_1 and i_2 are to be read in the primary oscillatory circuit. In most wireless telegraph plants the power supplied to the primary oscillatory circuit remains invariable with or without the aerial; the power in any manner wasted through action of the primary oscillations can be expressed by Ki^2, where K is a constant of the particular plant under test. It follows that the efficiency of transference of energy from the primary circuit to the aerial is

$$\frac{i_1^2 - i_2^2}{i_1^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

When there is a doubt as to the exactitude of premises stated one may determine with a calorimeter the powers h_1 and h_2 wasted by heat, without and with the aerial, in the primary discharge gap whose resistance may in some cases change; and we may measure the powers P_1 and P_2 supplied to the primary circuit without and with aerial, which is always easy. Then expressing the power wasted by the primary oscillations by the formula $Ki^2 + h$, K can be determined from $Ki_1^2 + h_1 = P_1$, and the efficiency is

$$\frac{P_2 - Ki_2^2 - h_2}{P_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

I am aware that K varies slightly if the oscillatory period of the primary circuit is affected by the pressure of the aerial, but the small errors that may be due to this cause will not lead to any such misconception of the matter as appears to be common.

It will be obvious to anyone wishing to carry out an absolute test of scientific accuracy that he can avoid the error which has been mentioned.

Regarding the principal point under debate, viz., the efficiency that can be obtained by application of Prof. Wien's impact method, I find in my notes referring to experiments made with direct current high tension (30,000 volts) that the variation of primary oscillation current when switching the aerial on and off was usually 1 to 2, showing efficiency of transference of energy from primary to aerial equal to

$$\frac{2^2 - 1}{2^2} = 75 \text{ per cent.}$$

Lyons, France, May 3. R. C. GALLETTI.

"ELECTRIC CABLES: THEIR CONSTRUCTION AND COST."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Under the heading "Electric Cables: their Construction and *Use*" in your current issue, you print a letter from "A Lover of Fair Play" on the subject of the attack on our book "Electric Cables: their Construction and *Cost*." As our book has nothing in it about the *use* of electric cables and, moreover, its chief aim is to determine the cost, I must ask you to kindly correct this in your next issue.

Your remarks at the foot of "Fair Play's" letter also refer to the above erroneous title, and at the same time infer that your reviewer had the courage to put his *name* to the review, whereas it is signed "F. J.," which may mean anything.—I am, &c.,

Old Charlton, May 6. F. O. HOWE.

[We regret the error mentioned. The inference, however, is without foundation.—ED. E.]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You were good enough to publish my protest against unfair reviews appearing in your columns and also to add a reply.

The charge of merely making assertions is funny, seeing that I gave concrete examples which you carefully avoid; for instance, on the question of copper coefficient. Your reviewer stated that the coefficient as given by Messrs. Coyle and Howe was wrong. I, with practically the whole electrical industry of this and other countries, say it is *right*, and any fairly well educated youngster of 14 can settle it by experiment and *prove* it is right. I consider that as your reviewer is wrong on such a simple matter it is more than probable he is wrong on such subjects as specific gravity, "quad cores," &c.

In my protest I did not ask for a "favourable" review, I asked for a "fair" review. Give both good and bad points as your contemporaries did when reviewing this particular work.

I made no statement that your reviewer accused the authors of being amateur. Your reviewer (innocently perhaps) suggested the work was written *for* amateurs; but I say your reviewer would be surprised if he knew how the professional cable manufacturers use the book daily.

Digitized by Google

Your last paragraph falls a bit flat, as your reviewer did not give his name but only initials, which can mean anything. It is difficult to realise that the engineer, "F. J.," is "well known in the cable industry" for his "good" works, when he is so lax with such an important item, as the copper coefficient is, to a cable manufacturer.

I regret I am compelled for business reasons to write under the *nom de plume* of

May 9. A Lover of Fair Play.

["A Lover of Fair Play" in our last issue made some general assertions apart from the review in question, and it was to these that our remark, as to the small value of assertions, applied. This was obvious. As to the temperature coefficient of copper we would remind our correspondent that the members of the Sub-committee on Cables were as follows:—*Chairman*, Robert Kaye Gray; *Representing the Admiralty*, C. H. Wordingham, L. J. Steele; *Representing the War Office*, Capt. A. H. Dumaresq, R.E.; *Representing the Crown Agents for the Colonies*, Llewellyn Preece; *Representing the General Post Office*, Martin F. Roberts; *Nominated by the Cable Makers' Association*, T. O. Callender, W. E. Gray, A. H. Howard; *Nominated by the Eastern Telegraph Co.*, H. A. C. Saunders; *Other Members of Committee*, Alexander Siemens, H. A. Taylor, A. P. Trotter.

With all due respect to a "Lover of Fair Play" we think that such a committee should know what is satisfactory; we suggest at least that between them they know more than the proverbial school boy. Nevertheless, we do not doubt that a letter of complaint written to the Secretary of the Engineering Standards Committee would receive every attention.—Ed. E.]

FARADAY SOCIETY.

At the meeting held on April 26th, at the Institution of Electrical Engineers, a general discussion took place on

"The Constitution of Water."

Prof. J. Walker, F.R.S., occupied the chair, and in opening the proceedings remarked on the extreme complexity of the problem of ascertaining the real nature of water, and on the great progress that had been made in recent years in the accumulation of quantitative data bearing on its solution.

Prof. P. Walden, of Riga, made the first contribution to the discussion in the form of a Paper entitled

"Is Water an Electrolyte?"

The Paper included a number of observations that had been made in order to determine whether water, when dissolved in a medium possessing powerful ionising properties, might not itself become an electrolyte. To secure an adequate answer to this question it was considered necessary to make use of media of which the specific inductive capacity was greater than that of water. The liquids selected were hydrogen cyanide (HCN), formamide ($H{\cdot}CO{\cdot}NH_2$), nitrosodimethylamine ($(CH_3)_2N{\cdot}NO$), formic acid ($H{\cdot}CO{\cdot}OH$) and sulphuric acid, the first two solvents being characterised by a specific inductive capacity greater than 84, the value of water. In passing, it may be noted that Prof. Walden's discovery of the use of formamide as a solvent represents a "find" of extraordinary importance, which even if it stood alone would form an adequate recompense for the labour involved in his masterly survey of the wide field of organic liquids. This solvent appears to reproduce nearly all the valuable qualities of water, including its convenient freezing point and boiling point and its powerful ionising properties, but will mix freely with important groups of compounds which do not dissolve to any marked extent in water.

Hydrogen cyanide, which with its high specific inductive capacity and great fluidity provides ideal conditions for electrolysis, was found when used as a solvent for water to give molecular conductivities of the order of 0·009, as contrasted with 300 for a salt such as potassium iodide; the low molecular conductivity of the water dissolved in hydrogen cyanide finds a parallel, however, in the low conductivity of hydrogen cyanide dissolved in water. Formamide, with a similar specific inductive capacity, but much smaller fluidity, gave for the molecular conductivity of water values (about 0·016) only slightly higher than in the case of hydrogen cyanide. In the case of formic and sulphuric acids the specific inductive capacity is lower than that of water, sulphuric acid being further handicapped by its extraordinary viscosity, but both solvents gave increased values for the molecular conductivity of water—namely, about 0·17 in formic acid, but rising in the case of sulphuric acid as high as 74. From these observations it is clear that the conductivity attributed to the water does not depend on the physical qualities of the solvent, but on some chemical relationship between solvent and solute. It was suggested by the author that water, acting as an amphoteric electrolyte, could form a salt when mixed either with a strong acid or with a strong base, and that the high conductivity of mixtures of sulphuric acid and water, and the slight conductivity of mixtures of formic acid and water, were due neither to free acid nor to free water, but to the presence of an oxonium sulphate or formate in the liquid. The absence of conducting power in mixtures of water with hydrogen cyanide or formamide was attributed to the weakness of their acidic and basic qualities and the impossibility of combining them with water to form a salt-like electrolyte.

Prof. Ph. A. Guye, having given a résumé of the results of diverse researches concerning the phenomena of molecular association, conducted both in his laboratory at Geneva and in that of Prof. P. Dutoit at Lausanne, showed how the conception according to which association was a simple phenomenon of chemical polymerisation permitted of our predicting various properties of associated liquids. He then indicated that it was even possible to calculate the order of magnitude of the association factor in the liquid phase if the degree of association or of dissociation were known in the vapour phase.

Mr. W. R. Bousfield, K.C., and Dr. T. M. Lowry read a Paper on

"Liquid Water a Ternary Mixture: Solution-Volumes in Aqueous Solutions."

The Paper described an extension to other solutes of some curious observations made five years previously in the case of aqueous solutions of caustic soda. The solution-volumes of the soda were found to vary largely with the concentration and with the temperature, the most remarkable feature of the variations being the occurrence of a maximum of solution-volume at about 60° C. in liquids of all concentrations. The gradual conversion of the ordinary slightly concave expansion curve into a strongly convex curve had now been traced through a series of solutes—chloral hydrate, sugar, acetic acid, silver nitrate, potassium, sodium, calcium and lithium chlorides. The authors conclude that the presence of three constituents in the liquid (ice, water and steam, or trihydrol, dihydrol and monohydrol) is absolutely necessary in order to account for the complex changes of volume that have been observed in water and in the solutions prepared from it.

Mr. W. Sutherland sent a written communication to the discussion in which he brought forward the view that water of crystallisation is solid hydrol in a special state. According to the writer's theory, water vapour, when nearly a perfect gas, is hydrol, H_2O. Ice is trihydrol $(H_2O)_3$. Water is a mixture of trihydrol and dihydrol $(H_2O)_2$, in varying proportions, at ordinary temperatures containing about one part of the former to two of the latter. The formula $(H_2O)_3$ for ice explains its crystalline form, the hexagonal prism. This the author pictures, assuming the electron theory of valency, according to which tetravalent O is an atom associated with three negative and one positive electrons, the electron pair being available for the purpose of joining the three oxygen atoms together, while the two negative electrons attach it to two H atoms through their positive electrons.

The author applies the hydrol theory to the consideration of solutions. He regards the ionisation of all electrolytic solutions as complete at all strengths. The so-called degree of ionisation is really the relative mobility of the ions; the original ionic theory ignored the electric forces acting between the ions and the ionising forces keeping the ions apart. When the ions are moved past one another in solution by means of an E.M.F., two viscosities of electric origin are encountered, one due to the electric forces between the ions and the water molecules, and the other due to neighbouring ions. Thus the mobility of an ion is proportional to the cube root of the concentration; the hypothesis of chemical union between ion and solvent is as unnecessary as the theory of partial ionisation. Nevertheless, a term is required for the mutual energy of ion and solvent. This theory of electrolytic solutions explains Walden's law on the dependence of ionic mobility on dielectric capacity and also Ostwald's valency rule. The effect of the solute on the solvent is also discussed.

Mr. H. Brereton Baker gave a striking experimental demonstration of the influence of purification in retarding the action of water on sodium amalgam. The conductivity of the water was a little lower than two reciprocal megohms. It is probable that non-conducting water, if it could be obtained, would be perfectly inactive chemically.

DEPOSITION OF ALUMINIUM FROM AQUEOUS SOLUTIONS, USING ROTATING CATHODES.*

BY S. A. TUCKER AND E. G. THOMSSEN.

From experiments carried on with copper and other metals deposited on a rotating cathode, it is known that the current density can be raised very greatly and the nature of the deposit be generally improved. It seemed possible that if the speed of rotation could be sufficiently increased, that the current density might be raised to such a high value that metals could be deposited from aqueous solution which under ordinary circumstances would not deposit at all. It was determined to try the effect of a rapidly revolving cathode in the case of aluminium, as it is well known to be impossible to deposit this metal from an aqueous solution upon a stationary electrode. High speeds of rotation are difficult to obtain, and the difficulties increase with the speed of rotation. The first experiments were therefore carried on with an electrically-driven cathode revolving at 3,200 revs. per min. The electrolyte was an aqueous solution of aluminium chloride or sulphate with an anode of sheet aluminium. The cathode consisted of a brass or copper rod of 5 mm. diameter. No sure indication of metallic deposit was obtained, but several times a black substance was found on the cathode on quickly removing it from the bath. Various changes were made in the conditions, such as variation in the current density and increase of rotation up to 3,500 revs. per min., which gave a rather more pronounced result, but nothing that could be called a coherent metallic deposit was obtained.

By using a very concentrated or pasty solution and rotating the cathode as fast as possible with the apparatus at hand, better results were obtained—the blackening was much more marked and was found to be invariably on the side of the cathode having the greatest peripheral speed due to the slightly eccentric motion of the revolving rod. This gave the clue to the requirements for depositing the metal, as it indicated the necessity of higher speeds of rotation and the use of pasty solutions. With the construction of a better bearing running at about 5,000 revs. per min., the deposits obtained were still black, but on closer inspection a trace of metal substance resembling aluminium was obtained. It was found that on quickly withdrawing the bath from the cathode, which was still revolving, that the deposit had a metallic lustre for a moment. However, it turned black almost instantly on exposure to the air. In order to raise the speed of rotation a small air turbine was constructed which enabled a speed of about 10,000 revs. per min. to be reached. With this apparatus much better results were obtained; the deposits on being first withdrawn from the electrolyte were metallic aluminium, but after a time tended to blacken on exposure to the air. This is probably due to the fine state of division in which it is formed at the cathode. In order to prove that the deposits obtained were really aluminium, they were carefully washed to free them from any adhering electrolyte and then dissolved in potassium hydroxide. As the deposits were very thin, a great many were dissolved in the solution in order to procure enough of the metal to subject to test. These tests left no doubt as to the certainty of the deposit obtained being aluminium.

One very noticeable fact in connection with the deposit is that the aluminium obtained at the highest speed retained its metallic lustre longer than when obtained at the lower speed. The blackening was hastened whenever the deposit was exposed to the air and whenever there was much water present in the electrolyte at the time of deposition. Several of the deposits were quickly placed in melted paraffin to protect them from the air and remained bright for weeks. After standing for a few days in the paraffin there was usually no tendency to blacken on again exposing to the air. The deposits were always extremely thin and, as before noted, invariably on the side of the cathode having the greatest peripheral speed. In the cases where the cathode ran perfectly true the deposit completely surrounded the rod.

The temperature of the bath must also be considered in such experiments. If the temperature exceeded certain limits no satisfactory deposit could be obtained. From a series of runs with various temperatures it was found that from 30° to 40°C. gave the best results. The time during which the electrolysis was conducted was for a few minutes only, since running for longer periods did not give as good results. Bad tendencies seem to increase with time. There was considerable variation in voltage and current due to change in resistance of the bath, probably due to several causes, such as formation of film, change of concentration, or vortex effect of the rapidly revolving cathode which tended to expose more or less of the cathode surface to the electrolyte.

It was thought advisable to obtain an air turbine of better construction than the one previously used, as any increase in speed would tend to give better results. The apparatus was used with compressed air at 30 lb. pressure and ran with very little vibration, giving a high speed of rotation. The revolving parts cause a hum which at high speeds is a piercing high note which is far from pleasant to work with, otherwise the apparatus is entirely satisfactory. The actual speed of rotation was estimated by comparison with a recording siren to be from 15,000 to 20,000 revs. per min.

On repeating the experiments with this apparatus the results obtained were somewhat better than before. It was found possible to burnish some of the deposits which were slightly black on a buffing lathe with rouge, the deposit then having the same appearance as polished aluminium.

The conditions under which these later experiments were conducted were as follows: Cathode: brass, 5 mm. diameter. Anode: sheet aluminium, 35 sq. cm. Electrolyte: pasty solution of aluminium chloride. Temperature: 30° to 40°C. Duration of electrolysis: 5 to 6 minutes. Revolutions of cathode per minute, 15,000. Current in amperes: two to four. Average voltage, 15. Current density at anode: 0·085 amperes per square centimetre. The deposit was only obtained on eccentric portion of the cathode, which portion had an area of 200 sq. mm., giving a current density at the actual cathode of 2 amperes per square centimetre.

The practical value of such a method for depositing aluminium is indeed small, as the quantity of metal obtained is but a small part of that theoretically obtainable for current used. The voltage necessary to conduct the experiments is also very high, and the practical difficulty of obtaining such speed of rotation is very great. The experiments are interesting, however, as showing that under certain conditions it is possible to obtain aluminium by electrolysis of its aqueous solutions.

* Abstract of a Paper read before the American Electrochemical Society.

MEXICO LIGHT & POWER CO.*

BY H. E. WEST.

Until a few years ago Necaxa, about 75 km. north-east of Mexico City, was noted as the site of one of Mexico's greatest waterfalls. Within the last seven or eight years it has carried especial interest as the location of one of the largest, if not the largest, electric power stations in Mexico. The Mexico Light & Power Co. has installed a plant, that, starting with modest proportions, has now assumed a stupendous scale. It is a Canadian enterprise, under the leadership of Dr. Pearson, closely allied to the interests which have recently concluded the San Paolo tramway and light plant in Brazil.

Power has been furnished for the last four years to Mexico City, operating there the tramways, mills and street and house lighting. From 10,000 H.P. to 12,000 H.P. has been utilised at El Oro, 175 miles distant, for operating mining machinery, mills and for lighting. To large consumers the charge is £10 per horse-power-year. The mines of Pachuca will soon be able to utilise this cheap and constant source of energy.

At the present time there are six 5,000 kw. hydro-electric generators installed, whilst two of 10,000 kw. are being added. This will normally increase the output to 50,000 kw. Each 5,000 kw. generator, however, can be run at 8,000 kw. Within two years, on the completion of the present installation, an out-put of 200,000 kw. is anticipated. The generators are of Siemens-Schuckert manufacture. A steam plant of 13,000 H.P. also exists in Mexico City, to render assistance at any time should occasion arise. To deliver 1 kw.-hour at Mexico City 'bus bars requires 1¼ cubic metres of water at Necaxa.

When the reservoirs at present completed and under construction are filled with the surplus waters of the wet season, the storage will be about 155,000,000 cubic metres, sufficient, with the present consumption, to last 300 days. In addition to this is the constant flow, which it is proposed to increase from the tapping of the watershed to the south.

The daily load varies from 20,000 kw. to 32,000 kw., probably averaging 24,000 kw. over the 24 hours. Each generator is fixed to a vertical shaft, at the lower end of which is the impact wheel, 9 ft. in diameter. The weight is 36 tons. At present the water efficiency is 73 per cent. By amended buckets and larger nozzles, the efficiency is expected to reach 86 per cent. Although at work over three years, no perceptible wear is noticeable on the steel buckets, notwithstanding that considerable sand is carried in the water.

* Abstract of an article in the "Mining World."

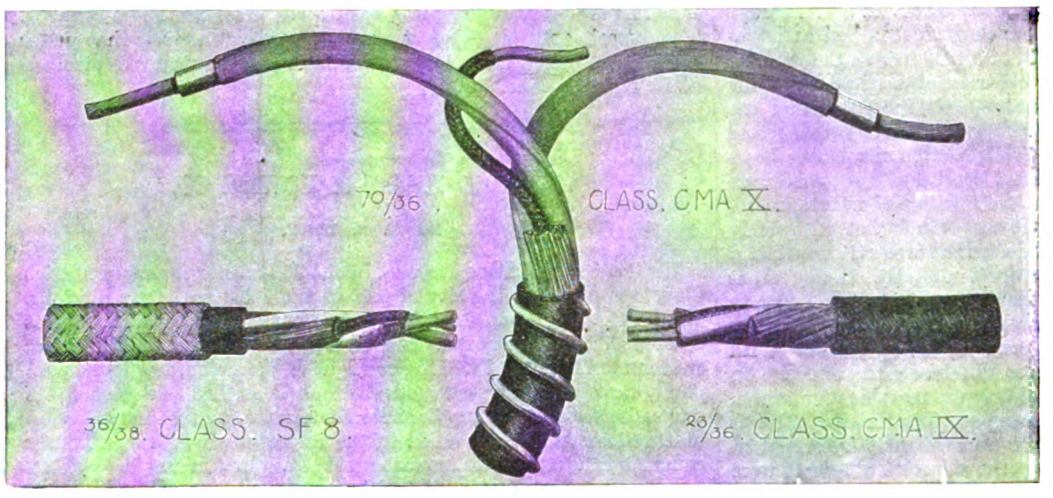
Digitized by Google

The generators run at 500 revs. per min. and generate at normal load 850 amperes at 4,000 volts. The pressure is transformed to 60,000 volts and the energy carried by a three-phase line, of No. 000 copper, on steel towers to Mexico City. There are four transmission lines carried on two sets of towers. From the city two transmission lines convey the current 125 miles to El Oro, where approximately 12,000 H.P. is constantly utilised. New windings are now being installed at the power house, so as to transform the energy to 80,000 volts.

The Necaxa power plant scheme started on a comparatively small scale, mainly the Necaxa reservoir and tributary waters. Then a larger scheme utilising both pressure and volume from the Laguna dam was proposed, and afterwards discarded. The waters from the Tenango and Catapuxtla rivers and various creeks will enable the capacity to be raised to 200,000 kw. Finally, the waters from the Coacoyuanca reservoir were secured, and from this latter scheme 300,000 kw. are anticipated. The capital of this enormous enterprise already amounts to £8,000,000, and there are employed 7,000 operatives, including 100 foreigners. The basis of the present and proposed operations covers 1,500 sq. km.

HENLEY'S TWIN FLEXIBLES.

Last week we mentioned that Messrs. W. T. Henley's Telegraph Works Co. had recently placed on the market a line of twin flexible cable bound up with an earthing core, in accordance with the Home Office regulations. We are now enabled to give in the accompanying illustration a general view of these cables, which are made in two distinct classes, the C.M.A. and the S.F.



EXAMPLES OF HENLEY'S NEW TWIN FLEXIBLE CABLES.

In the C.M.A. class the conductors are composed of high conductivity tinned copper wires 0·0076 in. in diameter (No. 36 S.W.G.), which are insulated with one coat of pure indiarubber and two coats of vulcanising indiarubber, taped with proofed tape. The earthing conductor is composed of high conductivity plain copper wires, 0·0076 in. in diameter (No. 36 S.W.G.), braided with cotton and compounded. The three cores (two insulated and one earthing core) are laid up to circular form with jute wormings, and are strongly braided and served over all with preservative compound. The insulation resistance of the finished cable is 600 megohms per mile at 60° F. after 24 hours' immersion in water and one minute's electrification. Two modifications of this cable are also made, one being fitted with an armouring of No. 18 galvanised-iron wire, and the other with an armouring of No. 30 galvanised-iron wire braid.

The S.W.F. conductors are composed of high conductivity copper wires 0·006 in. in diameter (No. 38 S.W.G.), lapped with cotton and insulated with two layers of vulcanising indiarubber. The earthing conductor is composed of high conductivity plain copper wires, 0·006 in. in diameter (No. 38 S.W.G.), braided with cotton and compounded. The three cores (two insulated and one earthing core) are laid up circular with jute wormings. They are then strongly braided and served over all with preservative compound. The insulation resistance is 300 megohms per mile after one minute's electrification. Two similar modifications, armoured respectively with iron wire and tape, are also made in this class.

LEGAL INTELLIGENCE.

Postmaster-General v. Tottenham Council.

On Tuesday the Railway and Canal Commission (Mr. Justice A. T. Lawrence, the Hon. A. E. Gathorne Hardy, and Sir James Woodhouse), heard an application on behalf of the Postmaster-General (who proposed to erect overhead telephone and telegraph lines in St. Anne's-street, Tottenham) against Tottenham Council. The P.M.G. applied under the Telegraph Acts 1863-1909 for the consent of the local authority to carry out the work but he was met with a refusal, and then the matter was referred to the county court judge of the district (Judge Wheeler) for arbitration. Having heard the parties, Judge Wheeler gave his award in favour of the Council, and the Postmaster-General now appealed.

Sir ROBERT HUNTER (for the P.M.G.) urged that the award of the County Court Judge was unreasonable; and for the local authority it was contended that the decision was reasonable, as the Council had themselves converted overhead lines into an underground system at a cost of £3,500, and had laid down since 1899 new underground lines at a cost of £2,500; and, further, the Postmaster-General himself had since 1899 applied to them for permission to lay down in the same thoroughfare underground lines for telegraphic communication and these lines had been laid down.

Sir ROBERT said the real point was the principle involved, as the P.M.G. was bound to consider economy and cost of outlay in these matters, because that cost was thrown upon the taxpayers. With regard to the danger and inconvenience which was expected to result in the erection of posts for carrying overhead lines, the danger was really negligible. With regard to the objection of future traffic it was very difficult to deal with speculative objections of that nature. As to tram lines running along the road, the P.M.G. was always willing to place his wires on the trolley poles; in fact, it was a common practice in new tramway Bills to insert a clause giving the P.M.G. that power.

Major W. A. J. O'MEARA, C.M.G., engineer-in-chief to the P.O., gave evidence, and said in some parts of London it cost as much as £800 a mile to lay pipes to take underground wires. The public were clamouring for a cheap telephone system, but he did not see how they were to secure it upon such lines as were now in dispute. In regard to the underground system there were difficulties which arose in cases of long distance telephhny. The electrostatic capacity of the cables was not so great when underground, and their efficiency for long-distance talking was consequently limited. With the overhead system that difficulty would not arise. In America so well was that recognised that long detours were made round the cities in order to avoid laying the wires underground.

Mr. Justice LAWRENCE pointed out that Tottenham Council had gone to considerable expense in preserving the underground system which they desired in their district, and he suggested the possibility of the Council making some offer to the P.M.G. in the way of a contribution towards the difference in the cost which would enable the parties to come to terms.

Mr. FREEMAN, K.C., said the Council were afraid the P.M.G. would establish a precedent in that matter, and pointed out that he was attacking many districts in connection with the telegraph and telephone systems.

Sir R. HUNTER said that many local authorities had already agreed to share the expense of an underground system by paying for the trenches, &c.

Mr. FREEMAN said his clients were willing to meet the P.M.G. inasmuch as they would do the whole of the work for £50 which the P.M.G. said would cost £84.

Sir ROBERT HUNTER said he could not accept this offer, and the hearing proceeded.

Mr. Freeman called evidence for the Council.

Mr. Freeman and Sir Robert Hunter having addressed the Commissioners,

Mr. Justice LAWRENCE, in giving judgment, said that they found that it was impossible to lay down a principle in these cases, and all they could do was to consider the whole of the circumstances and then give the best opinion on them they could. They felt most strongly the consideration urged by Sir Robert Hunter, namely that the Postmaster-General must consider economy in these matters in order that telephonic facilities might be extended as widely as possible and for his part in considering this particular case he could not find that the special character of the road would justify him in requiring the Postmaster-General to take a

Digitized by Google

course he was disinclined to take if that stood alone. He did not see that there was any such danger in an overhead line as would induce him to say that an overhead line could not be put up with safety nor did he think that the continuity of the road would be destroyed by such a line, but in that case it was a small matter, and the community had a strong feeling on the matter. Under the circumstances it seemed to him that it was a case in which one ought not to press the desire for economy against the views of the community and, therefore, they thought that if the authority undertook to do the work of laying the pipes, trenching, &c., for £50 they ought to say that the system adopted should be the underground system.

The other Commissioners gave judgment to the same effect.

The Law of Distress for Rent.

A Divisional Court (Mr. Justice Darling and Mr. Justice Bucknill) recently heard an appeal from a decision of the Lambeth County Court judge in an action, Shenstone *v.* Freeman, which raised the question of the exemption from distress for rent of goods let on hire. It appeared that plaintiffs (a firm of pianoforte dealers) sued defendant (a bailiff) for damages for the alleged illegal seizure of a piano belonging to plaintiffs in default of certain rent due in respect of the premises from which it was taken. The wife of the tenant of the premises obtained the piano from plaintiffs under a hire-purchase agreement, by the terms of which plaintiffs remained the owners of the piano until all the instalments under the agreement had been paid. Only one instalment had been paid when the piano was seized for rent due. Plaintiffs, following the procedure prescribed by sec. 2 of the Law of Distress Amendment Act, 1908, served a declaration upon the landlord of the premises, in which they stated that the piano was their property, and that the tenant had no right or beneficial interest in it, and subsequently instituted proceedings. Sec. 4 of the Law of Distress Amendment Act, 1908, provides that the provisions of the act exempting from seizure the goods of an under-tenant, lodger or other person not being a tenant of the premises, or having any beneficial interest in the premises, which may be upon the premises when a seizure is made, shall not apply " (1) to goods belonging to the husband or wife of the tenant whose rent is in arrear, nor to goods comprised in any bill of sale, hire-purchase agreement, or settlement made by such tenant, nor to goods in the possession, order or disposition of such tenant by the consent and permission of the true owner under such circumstances that such tenant is the reputed owner thereof. . . ." The County Court judge held that the seizure was justified on the ground that the piano was in the possession, order or disposition of the tenant by the consent and permission of the true owner, under such circumstances that he was the reputed owner of it. And he gave judgment for defendant. Plaintiffs appealed.

Mr. SIMON, K.C., submitted that the piano was not in the possession, order or disposition of the tenant, but of his wife, and, further, that even if that were not so, upon the facts before the County Court judge there was no evidence of any consent by plaintiffs that the husband should have possession of the piano or that he was the reputed owner of it. The piano, although it was the subject of a hire-purchase agreement, was not an agreement made " by such tenant," but by his wife. He submitted that the words " made by such tenant " must be construed to govern not merely the word " settlement " which immediately preceded it, but also the words " hire-purchase agreement " and " bill of sale."

Mr. ATKIN, K.C., for defendant, contended that evidence had been presented upon which the County Court judge was entitled to come to the conclusion of fact at which he arrived, and consequently no appeal lay.

Mr. Justice DARLING, in giving judgment, said in his opinion the piano, which had been let on a hire-purchase agreement to the wife, was (in the words of sec. 4 of the Law of Distress Amendment Act) " goods belonging to " plaintiffs. He thought the piano was not comprised in any hire-purchase agreement made by the tenant, because the wife (a Mrs. Wyard), who made the agreement for hiring the piano, was not the tenant. It was argued that the piano was in the possession of the tenant, but he did not think it was, although he was not prepared to say that there was absolutely no evidence that it was so. Granting, for the sake of argument, that the piano was in the tenant's possession, he thought that there was no evidence that it was in his possession by the consent and permission of the true owners. The words of the statute were " Goods in the possession, order or disposition of such tenant by the consent and permission of the true owner under such circumstances that such tenant is the reputed owner thereof." Even if it was in such possession, he did not think there was any evidence that it was in his possession in such circumstances that the tenant was to be taken as the true owner. He was not going to deal with the question whether the words " hire-purchase agreement made by the tenant " used in the act meant a hire-purchase agreement made by the tenant by which he granted the goods or whether they meant an agreement by which he hired them. He came to the conclusion that the words " shall not apply to any hire-purchase agreement " really meant a hire-purchase agreement to which the tenant was a party in some way. Take the case of a person who had given a bill of sale over some of his furniture, or the more simple case of a person who has got a motor on a hire-purchase agreement, and went to stay with a friend who owed his landlord rent. Suppose the landlord put in a distress for rent whilst the owner of the motor was stopping there. If the contention of defendant was right, that motor could be seized for the rent of the friend with whom the owner of the motor was staying. Did the Legislature really mean that ? He did not think so. It was perfectly true that the words might mean it, but there was authority for saying that all things are not exactly what they seem, and that was a statement particularly true of Acts of Parliament. He thought the words could be read in the way contended for by plaintiffs, and that such a reading was more consonant with what he thought they ought to mean than the construction put upon them by defendant. That being so, the appeal must be allowed.

Mr. Justice Bucknill concurred, and the appeal was allowed, with costs. Notice of appeal has been given.

Coslett Anti-Rust Synd. (Ltd.) v. Lennox.

On Friday, before Mr. Justice Joyce, plaintiffs moved for an injunction to restrain an alleged infringement of a patented process for coating metals to prevent rust.

Mr. HUGHES, K.C., for plaintiffs, said no question of the validity of the patent could arise, as defendant was one of the assignors to plaintiffs. Defendant said that the patent was invalid (but plaintiffs said he was estopped from asserting this), and that he had not infringed the patent. But he submitted on the evidence, including that of defendant himself, that he was infringing.

Mr. WALTER, K.C., for defendant, said infringement was denied, and offered the usual undertaking to keep an account.

Mr. HUGHES said on April 10, 1906, the patent was granted to one Coslett, whose name had been given to the process. In June, 1907, he assigned a quarter share to defendant and one-tenth to a Mr. Moore. On Dec. 20, 1907, a company was formed to take over the whole of the patent, and Coslett, Moore and Lennox joined in assigning the patent to the company. Lennox became a director. Lennox had ceased to be a director, and was carrying on business as the Coventry Anti-Rust Synd., which, it was alleged, involved the use of the precise process of plaintiffs or something very similar to it.

Mr. WALTER offered an undertaking not to use that process. He would undertake not to use any process in which electricity did not play a part. The defendant was using a process in which the essential part was the use of electric current. Plaintiffs' process was not an electrical process. He refused to give any undertaking with regard to that electrical process.

Mr. HUGHES : You are using our process plus the electric current.

His LORDSHIP : That may be an improvement.

Mr. HUGHES : If so we are entitled to it. We say defendant's process is a colourable imitation of ours.

Mr. WALTER contended that there was no warrant by an assignor that a patent was valid, and nothing to prevent him subsequently challenging its validity. What defendant was doing was not an infringement of the patent.

His LORDSHIP said that as there was a serious question of infringement, and also a bona fide issue as to the validity of the patent, it would be contrary to practice to grant an interlocutory injunction. Defendant must keep an account. There would be no order on the motion, except that costs should be costs in the action.

Luscombe v. Fryer.

On Wednesday, before Mr. Justice Parker, a motion was made on behalf of plaintiff to reverse the decision of the Official Referee (Mr. Muir Mackenzie) dismissing the action of plaintiff for damages for wrongful dismissal. The facts were reported in our issue of March 18. After hearing legal arguments, his Lordship dismissed the motion, with costs.

PARLIAMENTARY INTELLIGENCE.

SCOTTISH PROVISIONAL ORDERS.

At Edinburgh last week the Commissioners under the Private Legislation Procedure (Scotland) Act, 1899, held an inquiry into the draft provisional orders set down for consideration. The Earl of Kintore presided, and the other Commissioners were the Earl of Mansfield, Mr. J. S. Ainsworth, M.P., and Mr. Harry Hope, M.P.

DUNFERMLINE ORDER.

The order promoted by the Dunfermline & District Tramway Co. sought power to extend the undertaking, and to raise £90,000 additional share capital and to borrow £40,000, &c.

Mr. WILSON, K.C., for the promoters, said that when the order was originally presented 10 different extensions were contemplated, but the Wemyss Tramway Co. were also applying for power to extend their system to the north-east. Subject to the approval of the Commissioners the Dufnermline Co. decided to limit their claim for extensions to the north to the tramway from Lochgelly to Lochore. That company were seeking power to carry the tramway to Cardenden, but there was an understanding that that portion would be really for the benefit of the Wemyss Co. Both in the north and in the south the extensions were called for to serve large and increasing populations. It was now quite certain that there was to be a completed naval base at Rosyth, and the men employed in connection with the work would find it a great convenience if the tramway were formed. The company contemplated that the tramway should come down to the dock gates at Rosyth.

Evidence was given for the promoters, and an arrangement come to whereby the promoters undertook to widen markedly narrow parts of the road on condition that the County Council provided the ground for widening.

The preamble was passed subject to adjustment of clauses.

WEMYSS TRAMWAYS.

The consideration of the order asked by the Wemyss Tramways Co., which sought power to make extensions of their system was next pro-

Digitized by Google

ceeded with. The proposed tramway was unanimously supported by the surrounding villages.

The Commissioners desired that the promoters should not be given power to alter the position of the line as shown on the deposited plans to any greater extent than was commonly allowed. As to widening, the Commissioners were of opinion that where the tramway line was single, and occupied the centre of the roadway at any of the points on which they had heard evidence, the width of the roadway should be increased to 27 ft., and where the line was on the side of the road to 24 ft., the road authority to supply any extra land required free of expense to the promoters. Where 24 ft. could not be got the line must be doubled. As regarded the bridges, a provision should be inserted similar to that adjusted in the Dunfermline Order for the Cardenden Bridge (27 ft.).

KIRKCALDY ORDER.

The order promoted by Kirkcaldy Corporation asked for an extension of the burgh boundaries, authority to construct and work additional tramways, to extend the area of electricity supply, &c. The Corporation asked power to borrow for tramways £9,000.

After taking evidence and hearing counsel, Lord Kintore said the Commissioners were equally divided, and under these circumstances the clauses with regard to the extension of boundaries were refused. The adjusted clauses were considered on Friday.

JOINT ELECTRICITY SUPPLY PUBLICITY SCHEME.

The Electric Supply Publicity Scheme is now well under way. The Joint Committee's aim is to issue publications which will finally cover the whole area of supply possibilities.

USE THE ELECTRIC SUPPLY
ALREADY INSTALLED IN YOUR HOUSE
FOR IRONING.

A HOT IRON ALWAYS READY
BY MERELY TURNING A SWITCH.

The first step was taken by issuing a poster and showcard dealing with the use of the supply for general lighting, together with a typical circular with the same bearing, the whole of which was given gratifying and widespread support by various undertakings, both London and provincial (municipal and company owned). This has now been followed by the present issue of a poster and showcard, which deal with electric ironing, forming the first of a series dealing with the uses of the supply for domestic purposes. The poster (40 in. by 25 in.), lithographed in five colours, is of a design to make an effective display on the hoardings. The showcard is smaller (15 in. by 20 in.), but of identical design and colouring, and of a most tasteful character, and thus eminently suitable for display in showrooms, offices, shop windows, &c. (A reduced illustration accompanies this notice.) Further, as an extension of the foregoing, a handy-sized and illustrated four-page folder has been got out, which, while compact enough to be slipped into the ordinary envelope enclosing accounts or correspondence, is yet comprehensive enough to touch on all the domestic uses for lighting, heating and cooking, &c.

With the same end in view a mail card has been designed dealing also with electric ironing. This is in a size for enclosing with correspondence and bears an apposite illustration reproduced in colours. The present issue should be of the greatest service to supply undertakings, since it provides material for useful advertising without incurring expense in distribution. It thus marks a distinct step in advance.

COMMITTEE FOR PROTECTION OF ELECTRICAL INTERESTS.

It has been decided to abandon the formation of the Electrical Industrial Association of Great Britain, and a Committee has instead been created with the above title. We are informed by circular that, at a meeting on Friday last (the Hon. Arthur Stanley, M.P., presiding), the following rules were adopted:—

1. The primary object of the Committee is to endeavour to secure united action with a view to the protection and advancement of the commercial and legislative interests of the British electrical industries, and for that purpose to take such steps as may from time to time appear advisable, and to co-operate, as far as possible, with all institutions, societies and associations having similar or kindred objects.

2. The name of the Committee shall be the "Committee for the Protection of Electrical Interests," and may be shortly referred to as the "Electrical Committee."

3. The number of the Committee shall be limited to 80 members (besides the president, hon. treasurer and hon. secretary). Any casual vacancy may be filled by the Committee at an ordinary meeting.

4. Any gentleman connected with the electrical industry and receiving the support of not less than five members shall be eligible for election by the Committee. Election shall be by ballot; two black balls shall exclude, there being not less than six members present.

5. Every member of the Committee shall pay an annual subscription of one guinea, to provide for the expenses of the Committee; and any member whose subscription remains unpaid more than three months after it becomes due shall be liable to have his name removed by the Committee from the list of members.

The Committee (it is announced), in its collective capacity, starts with neutrality on all contentious matters. Proposals for the election of a president, hon. treasurer and hon. secretary will be submitted at a meeting of the Committee to be held at an early date.

Following is the first list of members of the Committee:—

G. L. ADDENBROOKE	E. H. FREEMAN	A. RASHLEIGH PHIPPS
J. F. ALBRIGHT	E. GARCKE	ARTHUR H. PREECE
A. BRUCE ANDERSON	WM. GEIPEL	W. LLEWELLYN PREECE
L. B. ATKINSON	J. BARBER GLENN	W. R. RAWLINGS
A. K. BAYLOR [DOES.	F. E. GRIPPER	J. S. RAWORTH
LT.-COL. H. R. BED-	ROBERT HAMMOND	H. B. RENWICK
H. R. BEETON	H. W. HANDCOCK	THEODORE RICH
E. BERGTHEIL	W. C. C. HAWTAYNE	J. R. SALTER
T. BROWETT	J. S. HIGHFIELD	A. H. SEABROOK
J. CECIL BULL	HUGO HIRST	STEPHEN SELLON
E. CHARRINGTON	F. HOPE-JONES	A. M. SILLAR
GEO. CONATY	E. M. LACEY	J. F. C. SNELL
A. N. CONNETT	J. G. LOBRAIN	C. P. SPARKS [M.P
W. B. COWNIE	J. A. LYCETT, J.P.	HON. ARTHUR STANLEY,
A. DICKINSON	W. L. MADGEN	J. GRICE STATTER
SYDNEY DOBSON	R. K. MORCOM, M.A.	A. A. CAMPBELL SWINTON
BERNARD DRAKE	SYDNEY MORSE	W. A. VIGNOLES
A. H. DYKES	W. C. MOUNTAIN	F. J. WALKER
H. JUSTUS ECK	W. M. MURPHY, J.P.	H. LAWS WEBB
G. K. B. ELPHINSTONE	LEE MURRAY	JOSEPH WETZLER
R. S. ERSKINE	F.H. NALDER [C.B.	W. B. WOODHOUSE
W. B. ESSON	HON. C. A. PARSONS,	A. P. WOOD
S. Z. DE FERRANTI	W. H. PATCHELL	

H. FOULDS ..... Electrical Standardising, Testing & Training Institution.
ALBERT GAY ..... Associated Municipal Electrical Engineers of Greater London.
T. B. GOODYER..... Metropolitan Association of Electric Tramway Managers.
L. G. TATE ..... Electrical Contractors' Association (Incorporated).
A. DE TURCKHEIM ... Incorporated Association of Electric Power Companies, Tramways & Light Railways Association
J. GLYNN WILLIAMS... Institution of Mining Electrical Engineers.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

A first-class man, with previous experience in small armature winding, is required. See an advertisement.

Applications are invited for the position of borough electrical engineer at Keighley. Candidates must be thoroughly trained engineers, with a knowledge of both h.t., three-phase alternating and d.c. supply. Applications to the town clerk, Mr. Wm. Bagshaw, Town Hall, Keighley, by May 18.

A lecturer in engineering subjects is required at Durban Technical School, Natal. Salary £250, rising by annual increments of £25 to £350 a year. Applications to Mr. W. A. Narbeth, Eltham, Kent, by May 23.

The professorship of physics at University College, Reading, will shortly become vacant. Particulars from the Registrar.

Digitized by Google

A lecturer in mathematics (to specialise in practical mathematics) is required at the Municipal Technical Institute, Belfast. Commencing salary £140, increasing to £180 per annum.

A junior lecturer and demonstrator in physics is required at the University of Sheffield. Salary £150 per annum. Applications to the Registrar by June 1.

Mr. Chas. W. Rycroft, of Battersea, has been appointed assistant electrical and mechanical engineer at Swindon.

Mr. C. Holman, assistant engineer at Surbiton, has been appointed engineer and manager of the Lymington Electric Light & Power Co., in succession to Mr. G. Salter, who has obtained an appointment at Hamilton.

Acton.—In reference to the note in our last issue (p. 162) to the effect that the Electricity committee had resolved to ask the electrical engineer (Mr. Blair) to send in his resignation, we are pleased to note that the Council referred the matter back, and that the vote of censure on a hard-working official has been rescinded.

Argentina.—The "Review of the River Plate" states that the Hippodromo and Centenario depots of the Anglo-Argentine Tramways Co., at Buenos Aires, are approaching completion, and that the latter will accommodate 200 cars. The rolling stock already comprised 1,300 motor tramcars and 400 trailers, to which are to be added 50 recently received from England and Belgium, 80 which will arrive shortly, and 50 which are being constructed in Buenos Aires.

Official approval has been given to the proposal of the Central Argentine Railway Co. to substitute electric for gas lighting on passenger trains.

The first section of the electric tramways in the town of Mendoza is to be ready for opening by the end of this year.

At a meeting of residents of General Belgrano (Buenos Aires Province) a proposal by Messrs. Matta & Fuente to form an electricity supply company was approved.

Aston.—At the Council meeting last week the Electricity committee's report stated that there was a profit of £4,694 on the past year, against £2,941 in the previous year. It was decided to place £2,000 to reserve and to apply £2,600 in aid of the district rate.

Asylum Lighting.—Metropolitan Asylums Board have entered into a fresh agreement with the County of London Electric Supply Co. for supply of electricity for lighting and power at Tooting Bec Asylum.

Australasia.—The "Australian Mining Standard" says Zeehan (Tasmania) Council have agreed to supply electric power to the Oonah Mines Co. at 2½d. per unit for a minimum of 3,600 units per week.

Statistics prepared by the Commonwealth statistician (Mr. G. H. Knibbs) show that at June, 1909, there were 389¾ miles of tramway in the Commonwealth States, of which 251¼ miles were worked electrically, 36 miles by horses, 56¾ miles by steam and 45¾ by cable. 179⅜ miles were owned by the Government and the same length by companies, the remainder (31 miles) being municipal. The gross revenue of the whole of the lines was £1,439,209 during the year, and the working expenses (of all except the Queensland lines—which could not be obtained) were £945,046. Queensland tramways produced £192,271 of the receipts. The total number of passengers was 226,775,000.

The revenue of the Commonwealth Postmaster-General's department for the year ended June, 1908, included £651,124 from telegraphs and £411,164 from telephones. Expenditure on cable subsidies, telegraph and telephone works, &c., during the same period was £392,036. At December, 1908, there were 3,411 telegraph stations and the length of telegraph lines was 44,554 miles. The total number of "one-state" telegrams increased from 7,162,927 messages in 1905 to 8,735,719 in 1908, and inter-State messages increased from 1,975,546 to 2,543,963. Cablegrams despatched and received in 1908 were 453,190, against 225,125 in 1901. The total amount spent on telephone construction to December, 1908, was £2,264,986, there were 285 telephone exchanges and 70,564 instruments in use. Rentals received during the year were £382,803 and cost of construction was £300,254. Telephone wires in use were 145,572 miles, compared with 47,276 at December, 1901.

Mortlake (Victoria) Shire Council have not adopted their committee's recommendation to borrow £2,500 for the erection and equipment of electricity works, and it is stated that the work will be carried out by a company.

Hobart (Tasmania) Council have decided to accept the offer of the Complex Ores Co. to supply electricity for lighting the city three years hence and a contract is to be prepared.

Electricity works at Korumburra (Victoria) will shortly be opened. Nearly all the business houses and many private residents have sent in demands for current.

The Melbourne Tramways & Omnibus Co.'s lease will expire in about six years, and there is an agitation on foot for the acquisition of their undertaking by the Melbourne Tramways Trust, which is composed of seven members representing Melbourne City Council and 10 representing the 10 suburbs served by the lines. The company's system comprises 43½ miles of cable tramway and 3¾ of horse line. The lines were constructed by the Trust and leased to the company for 32 years. The Minister for Railways (Mr. A. A. Billson) proposes that the Government should take over the tramways and work them by electricity in connection with the railways.

Recently Malvern (Victoria) Council were informed that the Tramway Trust had agreed to a modification of the plans, which had resulted in the line being laid close to the kerbstone in some places, but it was explained that an amended order in Council would be sought limiting the speed to 4 miles an hour at a corner where the line was near the kerb, and that "the conductor would precede the car on foot." The line will be opened about the end of May.

Hawthorn (Victoria) Traders' Association recently urged the Council to adopt electric lighting, and pointed out that every other suburb of Melbourne had electric light. In the draft agreement with the Melbourne Electric Supply Co. the right to supply power to any tramway that might be constructed would be conceded to the company, but the Council are opposed to this clause.

In reference to the recent discussion regarding the acceptance of the tender of the Fitzroy Dock authorities for the steam and electrical plant for the Lithgow (N.S.W.) Small Arms Factory, it is definitely stated that the tender of the Fitzroy Dock was £6,946, and that none of the tenders received in London were lower. Alternative full tenders by Messrs. Haes & Eggers (for the Lancashire Dynamo Co.) were £8,457 and £7,338, while their tenders for electrical apparatus only were £2,672 and £2,592.

The Defence Department has applied to the Governor-in-Council of Victoria for an order authorising the construction of an electric tramway to connect the Marebyrnong cordite works with the Essendon electric tramway at Newmarket.

Complex Ores (Ltd.) propose to generate electrical energy by means of water power from the Great Lake, and have offered to supply electric power up to 500 H.P. to Launceston Council at the same prices as those recently quoted by the company for a supply to Hobart Council—viz., 1¾d. per unit with a load factor of not less than 33 per cent., increasing to 3d. per unit if the load factor drops to 16 per cent.

Woollahra Council are considering the question of lighting the district (a suburb of Sydney) by electricity.

On March 9 the extension of Adelaide (N.S.W.) electric tramways to the western suburbs was formally opened. The chairman of the Tramway Trust said the inner circle, equal to 55 miles of single track, was now completed, and arrangements were in hand for 25 miles of construction in the outer circle.

Dunedin (N.Z.) electric tramways are reported to have earned a gross profit of nearly £30,000 during the year ended March 2.

Tolwong Mineral Co. (N.S.W.) have decided to instal electric power plant for working their new aerial tramways.

It is stated that Mr. M. W. Fink has withdrawn his offer to supply electricity in Brighton (Victoria), and the Melbourne Electric Supply Co., the only other tenderer, has already given the required guarantee of its ability to carry out the work.

Austria Hungary.—The Aussig local authorities have decided to construct an electric tramway 3½ miles in length, from Pokau to Tellnitz, at a cost of 270,000 kronen (£11,250).

Bangor.—The total income of the electricity department for the year ended March 31 was £30,540, against £30,497 last year.

After paying expenses the gross profit was £1,631. Interest was £875 and sinking fund £1,224. The year's deficit was £468, against £490 last year.

Barnsley.—The chairman of the Electricity committee (Ald. Brady) reported to the Council on Tuesday that though the introduction of metal filament lamps had reduced the consumption of electricity in the majority of cases by 30 per cent., the past year's working of the electricity department had been most successful. They had been enabled to strengthen the reserve, and the undertaking had never been in such a successful condition.

Birmingham.—The accounts for the year ended March 31 were presented to the Tramways committee on Tuesday.

The net profit was £56,442, and the committee decided to place £23,528 to reserve, the balance (£32,915) going to relief of rates. The last sum is £3,500 more than the amount given to relief of rates in 1909, and is regarded as satisfactory, as, owing to the decrease in the hours worked by the staff, the yearly wages bill has been increased by about £8,000. The increased profit is due to a general improvement of traffic.

On Wednesday the Electric Lighting committee decided to set aside £10,000 to relief of rates out of the past year's profits of the electricity department.

Bournemouth.—For the year ended March 31 the traffic receipts of the tramways were, with sundry receipts £85,540.

Expenses were £55,677. 4s. 4d., leaving gross profit £29,862. 11s. 8d., an increase of £3,325. 13s. 6d. over the previous year. The deficit is about £2,140.

Bridlington.—An unopposed inquiry was held on Wednesday into the application of the Council for permission to borrow £3,000 for extensions of the electricity works.

Canada.—The Public Utilities committee of Brandon recommend erection of electric power works and construction of electric tramways. It is proposed to put down four 187 kw. steam driven generators.

Digitized by Google

Medicine Hat Municipal authorities propose to establish an electric power plant, to be driven by natural gas, at an estimated cost of £10,250.

It is reported that application has been made to the Regina City Council by a new company, whose representative is Mr. Lawford Grant, general manager of the Canadian British Insulated Co. (Montreal), for a concession to construct an electric railway of about 8 miles in length.

The town of Bracebridge, Ontario, is erecting municipal electricity works.

Canadian Telegraphs.—The Canadian Pacific Railway and the Great North-Western Telegraph Companies recently put into effect the night lettergram service between all points in Canada and the United States. By this service lettergrams of 50 words or less can be transmitted for the same rate as a 10-word message, day rate, and one-fifth of this rate is charged for each additional 10 words or less. The letters must be written in plain English.

Chertsey.—The Rural Council have acceded to the application of the Woking Electric Supply Co. to be allowed to supply electricity to 29 houses in the parish of Chobham.

China.—Mr. Hewlett (acting British Consul) states that a Chinese electric lighting company was established at Changsha during 1909. The contract for the plant was awarded to a German firm.

Mr. Consul H. H. Fox, writing on the trade of Wuhu for 1909, says that the Wuhu Electric Light Co. (a Chinese company under Chinese management) commenced operations in May, 1909, and supplies current regularly to about 4,000 lamps in the native city. It is proposed to use electric power for the rice cleaning machinery in a local mill.

Colchester.—An inquiry was held last week into the Council's application for sanction to borrow £8,000 for the electricity undertaking.

The Town Clerk stated that the proposed loan was required for excess expenditure on previous loans sanctioned (about £934) and for new works, including £2,700 for five miles of mains. The mains were for districts where a supply of current would in the immediate future required For house services £1,125 was included. They had two generating sets, which had become too small for requirements, and the Electric Light committee desired to substitute for these one generating set, for which £1,300 was required. The Hythe and Lexden sub-stations, for which £960. 6s. 4d. was wanted, had already been put down, and were working satisfactorily.

On the advice of the inspector (Mr. H. Ross Hooper) the question of the generating set was left in abeyance, and other items were altered, the amount of the loan being reduced to £7,453.

Crewe.—It was reported to the Council last week that the net profit on the past year's working of the electricity undertaking was £1,219. £500 had been voted to relief of rates.

Darlington.—Application has been made for sanction to a loan of £1,500 for condensing plant.

Darwen.—There was a profit of £573 on the past year's working of the electricity undertaking.

Denmark.—Consul Liddell says the Copenhagen communal loan of 1910 (which amounts to about £2,000,000) will probably be devoted to the erection of power stations, amongst other works, during the next few years.

Dundee.—The Ward-road Brass Works have adopted electric lighting, and Messrs. Walker & Thomson, oil refiners are adopting the electric drive.

Eccles.—The Council offer to supply current to the Crown Theatre at 2½d. per unit subject to an undertaking being entered into that the supply shall not exceed at any time 25 kw., and that there be a guaranteed minimum yearly consumption of 25,000 units.

Electric Power on Tramways and Light Railways.—The Board of Trade have issued a revised edition of the regulations as to the use of electric power on tramways and light railways, which contain some slight amendments of the regulations issued in May, 1908.

Erdington.—It was reported to the Council last week that for the year ended March 31, the number of passengers carried on the tramways was 2,988,276, compared with 2,762,520 in 1908-9. Receipts were £13,953 (against £12,895). Receipts per car-mile were 11·06d. (10·49d.)

Fatalities.—In the Hamilton Sheriff Court on Thursday last an inquest was held on Alex. Hinshelwood, an electrician employed at the Glasgow Iron & Steel Works, Wishaw.

The foreman electrician, John Hill, stated that on April 2 he and deceased were executing repairs to an overhead electric charger. To make some tests he (Hill) went to the top of the charger and instructed deceased when he got the necessary signal to pull out the switch and replace the fuse. This was done twice, but on the third occasion, for some reason or other, Hinshelwood failed to pull out the switch, and he received a shock which proved fatal. The voltage of the current was 320. Deceased was a careful electrician, and had been four years at the works.

Other evidence was given, and the jury returned a verdict of death from electric shock.

An inquest was held on Monday on Geo. James Porter, superintendent at the Brush Electrical Engineering Co.'s Works, Loughborough.

It was stated in evidence that Mr. Porter was directing a test of a machine in which a fault had been found. He ran forward as the electric current was switched off and placed both hands on the machine to show another official the situation of the fault. The strength of the current was something like 2,000 volts, and he was killed almost instantly.

A verdict of accidental death was returned.

Gillingham.—The Council will supply electricity to the Naval Hospital at 1½d. per unit for power and at 2½d. for lighting.

Glasgow.—The Council have acquired 53,481 sq. yds. of land on the West side of Dalmarnock-road, at 8s. per sq. yd., for the erection of a new electricity generating station, &c.

Grimsby.—An unopposed inquiry was held on Tuesday into the Council's application for sanction to borrow £2,000 for superseding gas by electricity for street lighting.

The Inspector (Mr. H. Ross Hooper) pointed out that it was necessary to prove that the scheme was not going to be more costly than the present system, or that they were going to get something better at equal cost.

The borough electrical engineer (Mr. W. A. Vignoles) said that experiments had been made with metal filament lamps with highly satisfactory results. Not only did they get a much superior light, but they could do it at less cost than was paid to a private company for gas, and that, while the Corporation would lose a great consumer in the Great Central Railway Co., who, after November, would generate their own electricity, the saving in street lighting would go far to provide a profit as a set-off against the loss of £4,000 a year from the company.

Hackney (London).—The Electricity committee have had under consideration the question of developing the commercial side of the electricity undertaking and a deputation has visited the showrooms and offices of Marylebone and St. Pancras Councils, the Corporation of West Ham and also the Brompton & Kensington Electricity Supply Co.

In Hackney, since May, 1908, a sales department has been carried on in connection with the electricity undertaking, but it has suffered from the fact that there has been no show room and only one permanent officer, assisted by a temporarily employed clerk and assistant engineer. The committee are of opinion that the time has arrived when suitable premises should be taken in the vicinity of the town hall for the establishment of a showroom, and accommodation for those officers whose duty it is to deal more especially with the requirements of consumers as distinct from the generation of electricity. They have, therefore, made provisional arrangements to take premises in Mare-street.

Hampstead (London).—At the Council meeting last week the Lighting committee reported on the question of converting the whole of the street lamps from gas to electricity.

Previous to Dec. 20 last the inclusive charge per lamp-post per annum for a single upright incandescent burner was £3. 4s. 9d., but the Gas Light & Coke Co. offered to equip the posts with inverted burners and fully maintain them at an annual charge of £2. 19s. 10d. for the first five years, and afterwards at £2. 15s. 8d. per post per annum. On Feb. 24 the Lighting committee offered to take over the lighting of the whole of the posts, convert them to electricity, and maintain them at a cost of £2. 19s. 6d. per post for the first eight years, and afterwards at £2. 0s. 2d. per post per annum. This offer was conditional on all the lighting being handed over to them, and there were already some 340 lamps lighted by electricity, while Council had sanctioned the conversion of over 700 more, the materials for which were already largely in hand, and the work was being carried out. The Gas Company now offered to substitute an improved inverted burner, which they guaranteed would give an average of at least 60 c.p., at an inclusive cost of £2. 5s. for the first four years, and thereafter £1. 19s. 6d. for each post. This offer had been referred to the committee, and they had now prepared a proposal as follows, subject to the whole of the lighting of the borough being converted from gas to electricity :—

For posts fitted with two 35-watt lamps, £2. 5s. for first eight years and £1. 13s. 6d. subsequently; for posts fitted with four 35-watt lamps (or their equivalent), £3. 5s. and £2. 13s. 6d. (and 10s. per annum for every additional 35 watts). The following annual total cost of lighting the borough is based on there being 2,237 posts, fitted with one incandescent gas burner, or two 35-watt metal filament lamps. Present system, £7,242; inverted gas burners, £6,692 until 1915, and thereafter £6,226 (offer of Gas Company, Dec. 20, 1909). Electric incandescent, £6,655 until 1918, and thereafter £4,493 (scheme adopted by the Council Feb. 24 last); inverted gas burners, £5,033 until 1914, and afterwards £4,418 (offer of Gas Company March 16 last). Electric incandescent, £5,033 until 1918, and afterwards £3,747 (present proposal).

The committee recommended that the whole of the gas lamps in the borough should be converted to electricity under the scheme formulated.

Councillor Simmons moved that the report be referred back in order that the Council might avail themselves of the Gas Company's offer to fit up a trial installation of about 20 inverted gas burners for observation, and this was carried by 18 votes to 17.

Digitized by Google

Handsworth (Staffs.)—The Board of Trade have sanctioned the borrowing of £19,150 in connection with the purchase of the cable tramways. The period of the loan is 40 years.

The board have appointed Mr. Alfred Lyttelton, K.C., M.P., as arbitrator to settle the terms of the lease of the cable tramways to be granted by the Council to the City of Birmingham Tramways Co.

Harrogate.—The Council have unanimously passed the scheme of the borough electrical engineer (Mr. Geo. Wilkinson) for an additional 500 lamps to be converted from gas to electricity. Competitive schemes have been submitted by both the gas and electricity undertakings, and the saving by substituting electricity was found to be a substantial one. The cost per post to be charged to the Lighting committee for a 50 c.p. lamp (including renewals and all accessories) is 17s. per annum, the lamp being extinguished at midnight.

Hebden Bridge.—To encourage the demand for electricity the Council have resolved to grant to consumers a sliding scale of discounts.

Heckmondwike.—The Council have applied for sanction to a loan of £24,159, of which £19,959 is for excess expenditure on the electricity works, £3,000 for condensing plant, £1,000 for cables, and £2,000 for house services.

Holland.—Consul W. A. Churchill says, in his report on the Amsterdam district for 1909, that there is a vogue in the Netherlands at present for electric tramways and electric light and power, and it is anticipated there will be an active demand for electric plant during the next two years. The same may be said with regard to the Dutch East Indies, where 20 important concessions were granted last year, besides which it is rumoured that the Java State Railways will be electrified.

A steam tramway (60 miles in length) is to be constructed shortly to connect various villages in the Haarlemmermeer district, at an estimated cost of £600,000. The name of this company, Hollandsche Electrische Spoorweg Maatschappy, indicates that electricity may be used later.

The Noord-Zuid-Hollandsche Tramweg Maatschappy increased their capital last year by £270,000, in order to improve and electrify their lines between Haarlem and Leiden. The estimated cost of electrification is estimated by the company at £1,075 per mile.

The light railway system in the province of Groningen is to be considerably extended, and part, if not the whole, is to be electric. Arnhem municipality are considering projects for electrification and extension of the horse tramways.

The Holland Electric Tramway Co.'s concession for an electric tramway between Amsterdam and Wyk-aan-Zee has been withdrawn.

Three Westinghouse benzine-electric motor carriages have been ordered for the Ooster Stoomtrom tramways between Zeist and Arnhem.

The cost of engineering works in the Netherlands and the Dutch East Indian colonies during the next few years is approximately as follows:—

Netherlands: Electrification of light railways and extension of steam tramways, £2,000,000; erection of about 10 electric power stations, £500,000; gas and water works, £1,250,000.

Colonies: Electric light and power in 12 towns in Java, electric water power stations in four towns in Java, electric high-tension transmission in three provinces in Java and two electric motor 'bus services in Soerabaia and Samarang (Java), £5,000,000; Electrification of the Java State Railways, £13,000,000; railways and harbour works in Sumatra, £15,000,000; total, Netherlands and colonies, £40,000,000.

The number of electric motors in use in Amsterdam during 1908 was 7,015. The municipal supply was d.c. at 220 and the Electra Co.'s a.c. at 72 volts and 50 cycles.

Plans have been drawn up for the construction and working of electricity works for the towns of Deventer and Zwolle (Overijssel province).

Huddersfield.—It was reported at the Council meeting recently that the tramways account showed a surplus of £6,807, compared with £2,061 last year, and an amount equal to $3\frac{9}{16}$d. in the pound has been devoted to relief of rates after setting aside £12,250 for depreciation and meeting interest and charges for redemption of debt.

Ilkeston.—The capital expenditure on the Corporation's tramway undertaking at March 31 was £47,630, compared with £47,578 in 1909.

Last year's traffic receipts were £6,887 (against £7,116), total receipts £7,061 (£7,379), or 7·06d. (7·3d.) per car-mile; working expenses were £6,025 (£5,856), including £1,495 (£1,543) for power. 359,284 (368,195) units were used, 1·48 (1·58) per car-mile. Gross profit was £1,036, and net deficit, after meeting interest, &c., and providing for sinking fund contribution, £2,086 (against £1,636). The increase in operating expenses is stated to be entirely due to special expenditure on track and overhead equipment and increase in wages of staff. The engineer and manager (Mr. H. P. Stokes) states that the average expenses at Ilkeston are in excess of those of only 22 out of 76 municipal tramway undertakings of which he has prepared statistics, and the average for the 76 towns is 6·3d. per car-mile, against 6·02d. at Ilkeston. Mr. Stokes has not been successful in getting permission from the Board of Trade to fit roof covers on cars, but proposes to carry the matter further.

The revenue of the electricity department was £3,180, working expenses £1,981 or £1,788 (against £1,979), exclusive of special work in consumers' premises. Gross profit was £1,200 (against £780), and the deficit £86 (against £432). Units purchased were 314,476 (against 283,220). Current is taken in bulk for the electricity and tramway departments from the Notts & Derbyshire Electric Power Co. £350 is being placed to reserve on tramway account and £500 on electricity account.

India.—The "Indian and Eastern Engineer" states that the Railway Board has authorised the electrification of the Jhansi workshops of the Indian Midland section of the G.I.P. Railway.

The Central Jute Pressing Co. (Calcutta) are erecting a new jute press near Chitpore, which is to be driven electrically, the electrical plant being supplied by the Lahmeyer Electrical Co., and erected under the supervision of their chief engineer in India, Mr. H. R. Speyer. The Lahmeyer Co. are also supplying the electrical equipment for the new Ocean Jute Press of Seth Hursook Dass Dooly Chand at Chitpore.

Italy.—The electrification of the Savona San Guiseppe State Railway is to be continued to Ceva, making the electric line 28 miles in length.

Genoa Provincial Council have granted to a preliminary committee of capitalists a 30 years' concession for the construction and working of an electric tramway from Savona to Valdo. A company, with £32,000 capital, is to be formed to carry out the work, and it is anticipated that the line will be completed by the end of 1911.

Japan-British Exhibition.—This exhibition will be opened to-morrow (Saturday), but on account of the death of King Edward there will be no formal ceremony.

Llanelly.—The Llanelly & District Electric Light & Traction Co. have commenced the work of erecting a generating station. Current will be available about August.

London and Suburban Tramways.—Through tramway services from Aldgate to Leytonstone and Ilford were opened on Wednesday. The fare for the whole journey on either route is 3d.

London County Council.—On Tuesday it was agreed to allow Poplar Council to repay by quarterly instalments all loans for electricity purposes which are at present repayable on the annuity method. £13,450 for electricity supply was loaned to Woolwich.

Tramway Construction Works.—The adjourned recommendation of the Highways committee for the reconstruction of the horse tramways from Tooley-street to Deptford and the construction of authorised tramways from Evelyn-street to Nelson-street, Greenwich, was agreed to.

Draught Screens.—It was agreed to expend £1,064 in providing draught screens to the remaining 133 cars which were constructed without them.

Monaghan (Ireland).—The Council have decided to proceed with an electricity scheme prepared by Messrs. Curran Bros. at an estimated cost of £2,000.

Municipal and Health Exhibition.—This exhibition was opened at the Agricultural Hall, London, N., on Saturday last, and will remain open until to-morrow. There is little of an electrical character to be seen, and we would ask, Why this lack of enterprise on the part of electrical engineers. Municipal work of all kinds is a field in which electrical engineers have already done much, but there is still a great deal to be accomplished, and advantage might have been taken of such an exhibition to show the many ways in which electric light and power may be employed in municipal enterprise. It may further be pointed out that several gas features are to be found at the exhibition, and that where our rivals are hard at work advertising themselves it surely behoves us to be also.

On Richard Hornsby & Son's stand will be found practically the only apparatus in the exhibition likely to be directly of interest to electrical engineers. This company are showing one of their patent suction gas plants and engines coupled to a dynamo for lighting country houses and other similar buildings. This set supplies a motor, the whole being controlled by Ferranti switchgear.

Messrs. Babcock & Wilcox have on show a model of their well-known water-tube boiler, while an example of their water softener is to be seen in full operation.

New Caledonia.—Acting Consul Maning states in his report for 1909 that three nickel reduction works are in course of erection, that one (an electrolytic process) was almost ready to commence operations, and another was expected to start smelting by November, 1910.

Penmaenmawr.—The Board of Trade have extended the period of the Council's provisional order by 12 months.

Reduction in Telegraph Rates.—It is announced that on and after June 1, there will be a reduction in the rate per word for telegrams from this country to Argentine, Chili, Peru, Uruguay, Paraguay and Bolivia to 3s. 7d. per word, and to wireless stations established in Peru (Masisea, Orellana, Requena and Iquitos) to 5s. 7d. per word.

Road Board.—Under the terms of sec. 7 (1) of the Development and Road Improvement Funds Act, 1909, the following have been appointed members of the Road Board: Sir George S. Gibb (chairman), Lord Pirrie, K.P., Lord Kingsburgh (Lord Justice Clerk of Scotland), Lord St. Davids and Sir Charles D. Rose, Bart.

In consequence of his acceptance of the chairmanship of the Road Board, Sir George Gibb will shortly retire from the board of the North Eastern Railway, from the position of managing director of the Underground Electric Railways Co. of London, &c.

Digitized by Google

St. Pancras (London).—The borough treasurer, who has reported upon the report of the L.G. Board auditor on his audit of the Council's accounts for the year ended March 31, 1909, states that he has made arrangements with the Chief Electrical Engineer that for the future, as regards expenditure for mains, connections and meters, he will submit estimates of the cost for such purposes 12 months in advance.

South Africa.—The "British and South African Export Gazette" states that the Cinderella Consolidated Gold Mines are about to purchase a number of 5-ton skips and electric winders.

Johannesburg Corporation have recently purchased 8,000 tapered iron telegraph poles, 119 miles of covered wire and a quantity of tram rails, fish plates, bolts, &c.

Southwark (London).—The Electricity committee report that after considerable negotiation, the L.C.C. has agreed to the provision of recording instruments at the station, together with the necessary apparatus for taking records of pressure from pilot wires connected to the feeding points at the different places within the area of supply, in substitution for the four testing stations originally asked for. The cost of pilot wires and instruments is estimated at £370.

The Council will support Islington Borough Council in their attempt to get street boxes for electric lighting exempt from district surveyors' fees.

Spain.—The Spanish Minister of Public Works will (it is stated) shortly introduce a bill providing for an expenditure of £17,000,000 upon tramway and railway construction.

Stretford.—The Electricity committee has decided to put down an additional 500 kw. generating set, boiler and economiser, surface condenser and filtering plant, &c. Mr. T. L. Miller has been appointed to prepare specifications, to advise on the tenders, and to attend any loan inquiry at an inclusive fee of £140. The General Electric Co., British Westinghouse Co. and Lancashire Dynamo Co. have been asked to quote for the 500 kw. set, and Edward Heaton & Sons, Galloways (Ltd.) and Thomas Beeley & Son for the boiler, &c.

Telegraph Investments.—The stock and shareholders' meetings of a number of the leading telegraph companies are set out in the present issue of THE ELECTRICIAN, and are, in the main, interesting reading, as showing the settled value to investors of the stocks and shares of these companies. This satisfactory situation is emphasised in an article which appeared in the "Financier" (London) of May 10. In this article particular attention is drawn to the strong position held by these companies in respect to their very substantial reserves for all purposes.

Uruguay.—Concessions have been granted for the provision of telephone facilities in Maldonado by A. Zabala, in Carmelo, Colonia, and Colonia Arrue by Saturno Carbajel; and in an additional portion of Tacuarembo by Pedro Pomoli.

Venezuela.—A concession has been granted to the Provisional President of the State of Trujillo for the construction of a telephone line from Mendoza to Valera.

Walsall.—The L.G. Board has sanctioned loans for £8,345, including £1,000 for land, £1,250 for a sub-station, £1,404 for plant for sub-station, £3,691 for mains, and £1,000 for services.

Wednesbury.—The report of the electricity department for the year ended March 31 states that 433,267 units were sold, an increase of 209,559 units over 1909.

The receipts were £3,184. After paying expenses the gross profit was £1,485; interest and sinking fund charges came to £1,343, leaving a nett profit of £142. The ex-Mayor, in proposing the adoption of the report, said the report was very satisfactory. The scheme now in operation was economical, and the cost of supply compared favourably with that of larger undertakings. The charges were so moderate that many of the working classes were using electricity for lighting by means of slot meters. The total output had been nearly doubled during the year.

West Bromwich.—The Electricity committee reported to the Council on Wednesday that there was a decrease of £348 in the amount received from the sales of current during the past year, this being mainly brought about through a decrease in the amount received in respect of tramway traction.

West Hartlepool.—It was reported to the Council last week that the gross profit on the past year's working of the electricity undertaking was £6,888, an increase of £414 over 1909. Interest absorbed £2,475 and repayment of loans and sinking fund £3,296. The net profit is £1,128, against £584. The balance has been added to reserve. The net outstanding capital expenditure is £66,000.

Wireless Telegraphy.—We have already referred to tenders received by the Commonwealth P.M.-G. for the erection of wireless stations at Sydney and Fremantle. Further particulars are to hand from which it appears that five tenders were received, and that of the Australasian Wireless (Ltd.) has been accepted at £4,150 for each station. The next lowest was £7,000 each, but did not comply with the conditions, &c. Two other tenders were for £7,777 and £9,317. 10s. per station respectively, the highest being £19,020 per station! The successful tenderers are stated to have guaranteed a speed of 1,000 letters per minute, "whether by the oral method or by records." Australasian Wireless (Ltd.) is a new company, formed to acquire the rights for Australasia of the Telefunken system. The work is to be completed in 52 weeks from acceptance of tender under a £10 per week penalty. A further provision of the contract is the forfeit of £500 and the plant, so far as completed, to the Commonwealth in case of failure to carry out the contract. The station at Sydney is to be situated either at the North or South Head and the Fremantle station is to be either at Rottnest Island or on the hills behind the harbour.

Dinner.—Last week a dinner was given to celebrate the coming of age of the Bournemouth & Poole Electricity Supply Co. The whole of the dinner was cooked by electricity, and the oven and all other apparatus were installed in the dining room.

Amongst those present were: Mr. A. H. Sanderson, J.P. (chairman), Dr. J. Atkinson Hosker, J.P. (vice-chairman), Mr. H. P. Croft (M.P. for Christchurch), Mr. H. B. Renwick, Mr. W. D. Brightman, Mr. E. L. Ingram, and many others.

Mr. H. B. RENWICK, in proposing the toast of "The Chirman, Vice-Chairman and Directors of the Company," said he was one of the oldest members of the company, and it was now 21 years ago since the Bournemouth Electricity Co. commenced a public supply in Bournemouth in a modest way, from the overhead cable lighting system in the centre of the town. That modest undertaking was taken over by the Bournemouth & Poole Electricity Supply Co. 19 years ago, and had grown up to its present state of prosperity. A prospectus issued 19 years ago contained the statement that they had 60 consumers, 1,000 8 c.p. lamps connected and £3,000 revenue in excess of expenditure. He joined the staff as secretary some four years later, and they had then increased to 19,000 8 c.p. lamps connected, 250 consumers and a gross revenue of £7,350. Now they had 5,000 consumers, 200,000 8 c.p. lamps connected and the gross revenue was £57,000. The company had grown to one of the largest in the United Kingdom.

Mr. A. H. SANDERSON, in responding, said he felt it a great honour to be the chairman of the company. The management had been successful in steering the ship into calm waters, and they were now enjoying great prosperity.

Dr. J. A. HOSKER proposed the toast of "The Guests," and Mr. H. PAGE CROFT, M.P., replied.

The CHAIRMAN, who proposed the "Health of the Staff of the Bournemouth & Poole Electric Supply Co. (Ltd.)," complimented the company on the excellency and efficiency of their staff and employés.

Mr. E. L. INGRAM and Mr. W. D. BRIGHTMAN responded.

Yarmouth.—On the recommendation of the General Purposes committee it has been decided to convert 192 gas lamps to electric lamps during this and next year. It is estimated that a saving of £76. 6s. 8d. per annum will be effected.

In a report on the existing arc lights, which number 186, and cost £2,375. 12s. per annum, the surveyor suggests converting them to flame arcs, and 400 c.p. incandescent lamps, which will effect a saving of £200. 19s. 6d. This suggestion has also been adopted.

Electrical Football League.—The annual general meeting will be held on the 18th inst. at the offices of the St. James' & Pall Mall Electric Supply Co., 19, Carnaby-street, Golden-square, London, W. All football clubs attached to electrical firms within 15 miles radius of Charing Cross are invited to send two representatives, as the council are anxious to increase the number of clubs. Particulars can be had from the hon. secretary (Mr. H. W. Roberts), 71, Queen Victoria-street, London, E.C.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

NEWPORT (Mon.) Electricity committee invite tenders for supply and erection of two 400 kw. motor-generators, three-phase to d.c.; one 600 kw. motor-generator, three-phase to single-phase; and one 'bus-bar three-wire booster. Specifications, general conditions and form of tender from the borough electrical engineer and tramways manager, Mr. H. Collings Bishop, Town Hall, Newport, Mon. Tenders to the Town Clerk by first post May 31. See also an advertisement.

COVENTRY Electricity committee invite tenders for supply, delivery and erection of a 1,250 kw. turbo-alternator, complete with surface-condensing plant, &c., four water-tube boilers (straight tube type) and two fuel economisers. Specification, general conditions and forms of tender from the engineer and manager, Mr. Geo. Tough, and tenders to the Town Clerk, Hay-lane, Coventry, by first post May 30. See also an advertisement.

The Corporation of the City of LONDONDERRY invite tenders for supply, delivery and erection of a 400 kw. mixed-pressure d.-c.

Digitized by Google

turbo-generator, condenser, pipe work, floor plates, &c., switchboard panels, instruments and connections, economiser, dampers, pipes, valves, &c., and feeder cable, connections, &c. Specifications, &c., from the city electrical engineer, Mr. R. V. Macrory. Tenders to be addressed to the Town Clerk, Municipal Offices, Londonderry, by May 21. See also an advertisement.

The Tramways and Electricity committee of BELFAST Corporation invite tenders for motor boosters and switchgear and extension of lighting switchboard. Specifications, &c., from the city electrical engineer, Mr. Thos. W. Bloxam, M.I.E.E. Tenders to the Town Clerk, City Hall, Belfast, by 10 a.m. May 23.

St. Pancras (London) Borough Council invite tenders for supplying 21 flame arc lamps with 20 suitable iron cradles. Copies of specification, conditions of contract and form of tender from the electricity department offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk (Mr. C. H. F. Barrett) Town Hall, Pancras-road, London, N.W., by noon, May 23.

SOUTHAMPTON Corporation invite tenders for supply of a 1,000 kw. steam generator, boiler, alternator and motor alternator. Particulars, specifications and forms of tender from the borough electrical engineer, Mr. H. F. Street, electricity works, Western Shore, Southampton. Tenders to the town clerk, Mr. R. R. Linthorne, Municipal Offices, Southampton, by May 24.

The Lighting committee of DUBLIN Corporation invite tenders for supply and erection of flame arc lamps and arc lamp pillars. Specifications, &c., from the city electrical engineer, Mr. Mark Ruddle, Fleet-street, Dublin. Tenders, addressed to the Chairman of the Lighting committee, 3, Cork-hill, Dublin, by May 20.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

LEICESTER Tramways committee want tenders for supply of mixed pressure steam turbine direct-coupled to 750 kw. d.c. generator, with condensing plant, switchboard, &c., and two Lancashire boilers, with fuel economiser, piping, &c. Forms of tender from the Tramway Engineer, Belgrave-road, Leicester.

CROYDON Corporation want tenders by 11 a.m. May 26 for lighting the two isolation pavilions and additions to the administrative block of the Borough Hospital, Waddon. Specification, &c., from the Borough Engineer.

The Commissioners of H.M. Works and Public Buildings want tenders by May 17 for steelwork of Glasgow labour and telephone exchange. Forms of tender, &c., from 3, Parliament-square, Edinburgh.

CLACTON Council invite tenders for annual supplies for the electricity department, including electrical service fittings, joint box compound, oils, cotton waste, bitumen, &c. Tenders to the Clerk by noon May 23.

DARLINGTON Electricity committee want tenders by May 25 for a cooling tower, electrically-driven centrifugal and air pumps and a boiler feed pump. Specifications, &c., from the Borough Electrical Engineer.

ST. PANCRAS (London) Council require tenders by noon May 23 for 12 months' supply of steam coal to their electricity stations. Specifications, &c., from the Electricity Department, 57, Pratt-street Camden Town, N.W.

ROCHDALE Electricity committee want tenders by noon May 25 for supply and erection of battery of accumulators, reversible booster and switchboard panels. Specification, &c., from the Borough Electrical Engineer.

RHYL Council want tenders by May 23 for 830 yds. of 0·125 and 370 yds. of 0·2 triple concentric cable. Specifications, &c., from Mr. E. H. Wright, electricity works, Rhyl.

BATLEY Corporation require tenders by noon June 1 for a lighting and traction switchboard for the electricity works. Specifications, &c., from the Borough Electrical Engineer.

MANCHESTER Tramways committee want tenders by 10 a.m. May 24 for supply of steel girder tram rails and granite setts. Specifications, &c., from the General Manager.

FINCHLEY Council want tenders by 11 a.m. May 28 for sinking a deep tube well at the electricity works. Specification, &c., from the Electrical Engineer, Squire's-lane, Finchley.

REIGATE Council want tenders by May 21 for fire-alarms, &c. Specification, &c., from the Town Clerk.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zincs for batteries. Local representation is necessary.

The acting Town Clerk, WELLINGTON (N.Z.), will receive tenders until 4 p.m. May 19 for supply of six pairs of electric tramcar trucks. Specifications from the Engineer and Manager, or can be seen at 73, Basinghall-street, London, E.C.

The Board of Control, WINNIPEG (Canada), will receive tenders until May 16 for supply of conduit, construction of conduit runs, and supply of sub-station transformers and switching apparatus. Specifications, &c., from the Power Engineer, Winnipeg.

The Deputy Postmaster-General, PERTH (W. Australia), will receive tenders until 3 p.m. May 24 for supply of four 40 ft. and 10 50 ft. steel towers. Local representation necessary.

TENDERS RECEIVED AND ACCEPTED.

London County Council have accepted the tenders of the following firms for tramway fittings and equipment :—

British Westinghouse Co., Dick, Kerr & Co., British Insulated & Helsby Cables, London Electric Wire Co. & Smith's, Liverpool Electric Cable Co., General Electric Co., Western Electric Co., Callender's Co., India Rubber, Gutta Percha & Telegraph Works Co., G. McLellan & Co., North British Rubber Co., J. G. Ingram & Son, Irwell & Eastern Rubber Co., F. Mountford, Brecknell, Munro & Rogers, Imeson, Finch & Co., T. Bolton & Sons, Dyer & Young, P. Hooker, A. Cort & Co., Micanite & Insulators, British Isola Co., Roburine Co., Ebonestos Mfg. Co., Wiggins & Sons, A. Round, Crystalate Mfg. Co., Bullers (Ltd.), Doulton & Co., F. W. Rowlands & Co., W. C. Wrigley & Co., J. Holroyd & Co., Hadley Bros., West Bromwich Spring Co., G. Salter & Co., J. Steel & Sons, Tempered Spring Co., Smith Bros. & Hill, Lion Spring Co., Dart Spring Co., Highton & Co., Player & Mitchell, G. D. Peters & Co., Hurst, Nelson & Co., Howarth & Hanson, E. Showell & Sons, Gabriel & Co., United Electric Car Co., Anti-Attrition Metal Co., Davis & Timmins, Deptford Engineering Co., F. W. Cotterill, Bayliss, Jones & Bayliss, E. H. Bentall & Co., Smethwick Stamping Co., Armstrong, Stevens & Son, Derited Stamping Co., J. B. Brooks & Co., Wilkes (Ltd.), C. Dunn (Ltd.), Woodall & Co., Central Marine Engine Works, Hunter & English, Blake Boiler Wagon & Engineering Co., Warren & Sons, East Ferry-road Engineering Co., Head, Wrightson & Co., C. Bunn (Ltd.), J. Williamson & Co., Northampton Direct Castings Co., T. Summerson & Sons, J. Crowley & Co., National Rail & Tramway Appliances Co., J. Martin & Son, Davis Gas Stove, Diamond Foundry, J. Wells (Ltd.), Brydon & Co., J. Crowley & Co., S. Osborn & Co., Cammell, Laird & Co., W. Shaw & Co., Hadfield's Steel Foundry Co., Edgar Allen & Co., T. Firth & Sons, T. Bolton & Sons, Isaac Storey & Sons, P. & W. McLellan, Frodingham Iron & Steel Co., Dermatine Co.

London County Council have also accepted the following tenders :

A. N. Coles (lowest tender) for roadwork and platelaying for reconstruction of tramways from Tooley-street to Deptford, £123,675. 19s. 10d. (Three tenders received; highest £133,920. Chief engineer's estimate £132,701. 0s. 2d. Mr. Coles is to be allowed to sublet the plough box covers and rain drain boxes to Hadfield's Steel Foundry Co., yokes and castings to the Anderston Foundry Co., tie rods, bolts and nuts to Bayliss, Jones & Bayliss, and jumper cables to Callender's Co., W. T. Henley's Co. and General Electric Co.)

David Bridge & Co. for shafting bearings, brackets, &c., for second section of central car repair depot, £456. 18s. (One other tender received, £553. 8s. Chief officer's estimate £510. Messrs. Bridge & Co. are to be allowed to sublet portions of the work to the Empire Roller Bearings Co.)

Alley & MacLellan (lowest tender) for air compressor and receiver for second portion of central car repair depot, £187. 10s. (Seven tenders received; highest £275. 10s. Chief officer's estimate £250. Messrs. Alley & MacLellan are to be allowed to sublet the air receiver to Muir & Findlay or T. Balmforth, and valves to Dewrance & Co.)

Patent Shaft & Axletree Co. for 4,800 steel driving wheel tyres for tramcars at 21s. 6d. each. (Sixteen tenders received; highest 50s. 9d., lowest 17s. 1d. Four were lower than the accepted tender, but the schedule as to wages was not filled in.)

John Batt & Co. for 1,600 steel tyres for driving wheels of tramcars at 15s. 9d. each. (Fifteen tenders received; highest 30s. Three were lower than the accepted tender, but the schedule as to wages was not filled in. Messrs. John Batt & Co. are to be allowed to sublet to Bochumer Verein Stahlwerke (Bochum, Germany) and the Vereinigte Stahlwerke van der Zypen und Wissener Eisenhütten A.G. (Cologne-Deutz, Germany, the manufacture of the pony-wheel tyres.)

Edinburgh Corporation have accepted the tender of the Lahmeyer Electrical Co. for supply of insulated cable for the year ending May 15, 1911, amounting to £5,202. 17s. 9d.

At the Council meeting questions were asked as to the tenders submitted, and in reply Mr. STEVENSON said any firm would accept the contract on the terms laid down by the Council with regard to standard wage, but the Council had no knowledge of whether the firm would pay the standard rate of wages. In their country the conditions of labour

Digitized by Google

were entirely different. The point was that the Council was saving £660 on the contract. He moved approval, mentioning that the lowest British tender was £600 dearer.

Mr. RAWSON complained that the Council were penalising their own workmen and allowing foreigners practically to take the bread out of their mouths. He moved that the order be given to the British firm whose tender was next to the one mentioned.

This motion was carried by 23 votes to 9.

Hammersmith (London) Council received the following tenders for cables, the names in parentheses indicating where the cable was made: Western Electric Co. (*accepted*), **£660** (Woolwich); Standard Cable Co., £625 (Germany); Union Cable Co., £658. 4s. 9d. (Germany); Aubert, Grenier & Co., £672 (foreign); Callender's Cable & Construcion Co., £700 (Erith); Siemens Bros. & Co., £700 (Woolwich); Johnson & Phillips, £700 (Charlton); British Insulated & Helsby Cables, £705. 9s. 4d. (Prescot); W. T. Henley's Telegraph Works Co., £710 (London); W. T. Glover & Co., £715 (Salford); General Electric Co., £735. 8s. 9d.; Craigpark Electric Cable Co., £948. 16s. 6d. (Glasgow).

Wigan Corporation have accepted the following tenders for annual stores:—

General Electric Co., Dorman & Smith, Eckstein, Heap & Co., Metallic Seamless Tube Co., H. G. Mayer & Co., and Morgan Crucible Co., electrical accessories; Baxendale & Co. and General Electric Co., electric lamps; John Bolton, T. Tyldesley, G. Makinson and I. Sandback, engine room stores.

Dick, Kerr & Co., Hele-Shaw Clutch Co., Fleming, Birkby & Goodall, Brecknell, Munro & Rogers, Watlington & Co., Boydell & Co., L. Andrew & Co., British Westinghouse Co., S. Cook & Co., A. Clare & Co. and P. R. Jackson & Co., tramcar accessories; R. W. Blackwell & Co. and Imeson, Finch & Co., overhead material; R. Young & Co., engine room stores.

Bermondsey (London) Council have accepted the following tenders:—

Electricity meters, British Thomson-Houston Co. and Ferranti (Ltd.); time switches, Ferranti (Ltd.); demand indicators, Reason Mfg. Co.; cut-outs, General Electric Co.; ceiling troughs and terminals, General Electric Co.; standard fuses, General Electric Co.

Walsall Council has accepted the following tenders:—Rees Roturbo Mfg. Co., new transformer and switchgear, £715; Callender's Co., laying new trunk main, £1,286. 14s. 2d., and extending feeders and laying l.-t. cables £1,075. 13s. 7d.

Keighley Council have accepted the following tenders:—

E. Green & Son, economiser, £165; British Thomson-Houston Co., Tirrill regulator, £250; British Westinghouse Co., transformer and switchgear, £245. 18s.

Heckmondwike Council have accepted the tender of W. T. Henley's Telegraph Works Co. for cables for extensions to the premises of the Bradford Dyers' Association.

Walsall Council have accepted the tender of Callenders' Co. for cables at £2,361. 13s. 7d., and the Rees Roturbo Mfg. Co. for transformer and switchgear, £715.

Worksop Council have accepted the tender of the Mordey-Fricker Electricity Meter Co. for the supply of 50 prepayment meters at 43s. 9d. each.

Hammersmith (London) Council have accepted the tender of H. Mansfield for three-way ducts at £246. 13s. 4d., less 2½ per cent.

The Bastian Meter Co. have again secured the contract for 5 ampere meters at Edinburgh.

Southend Council have accepted the tender of Walter Scott (Ltd.) for 50 tons of 40 ft. tram rails at £7 per ton, plus 5s. for royalty.

Buxton Council have placed an order with Ferranti (Ltd.) for meters.

Huddersfield Council have accepted the tender of J. Marsden & Son for wiring the Birkby schools at £119.

Eccles Council has accepted the tender of Bertram Thomas for the extension of a traction switchboard for £48. 10s.

Lancaster Council have accepted the tender of E, Green & Sons for the renewal of economisers, at £120.

The tender of Messrs. Siemens Bros. Dynamo Works has been accepted by Walthamstow Council for supply of Tantalum lamps.

Dartford Council have accepted the tender of Johnson & Phillips for cables, and that of the Universal Electrical Mfg. Co. for a feeder pillar.

The contract for the electric lighting of St. Paul's Cathedral, Dundee, has been secured by Mr. T. C. Keay.

Johannesburg Corporation have placed orders with W. T. Henley's Telegraph Works Co. for 1,000 pairs of cut outs, and with Fraser & Chalmers for tram rails, fish plates, bolts, &c.

The Commonwealth Postmaster-General's Department, South Australia, has accepted the tenders of the British Insulated & Helsby Cables for jointing sleeves and switching cords; Western Electric Co. for condensers, switching and three-conductor cords; Gibbs, Bright & Co. for h.d. copper wire; W. Wallis for w.i. brackets for railway rails; Williams & Co. for iron spindles for insulators; H. Rowe & Co. for ammeters; and J. Bartram & Sons for condenser telephones.

BUSINESS NOTICES.

The partnership between Morgan Ivan Manderstjirna Williams and Harold W. Couzens (carrying on business as Morgan Williams & Couzens), consulting engineers, 39, Victoria-street, London, S.W., has been dissolved. Debts by Mr. Couzens, who continues the business under the old name, and at the same address.

Frank B. Hellon and Herbt. P. Tavernor (trading as F. B. Hellon & Co., electricians, 57, Moorfields, Liverpool) have dissolved partnership. Debts by Mr. F. B. Hellon, who continues at the same address.

Plant for Sale.—Eastbourne Corporation advertise for sale a 50 kw. steam alternator. Particulars from the borough electrical engineer, Mr. J. K. Brydges.

"Railway and Travel Monthly."—The first number of this magazine is just issued. Its articles range over railway matters in general, the most interesting being those descriptive of "Twentieth Century Railway Development," the new locomotive works of the London & South-Western Railway at Eastleigh, and "British Express Trains and Locomotives." We hope our contemporary will not fail to remember that there is an electricity section of railway working.

Kelly's Directory of the Building Trades.—We have received from Messrs. Kelly's Directories (Ltd.), 182-184, High Holborn, London, W.C., a copy of the 11th edition of this well-known directory, which contains 2,530 pages (exclusive of indexes) and about 300,000 classifications.

The directory is designed to give complete lists of all the various professions, trades and businesses connected with the constructive arts, and the publishers have spared no pains to make the new edition as complete and accurate as possible. No distinctions are made in the directory; a small town, if a builder carries on business in it, finds a place equally with the large provincial city or the metropolis itself. The work, which is as reliable as it is possible to make a book of so comprehensive a character, contains: (1) Lists of metropolitan, county and borough surveyors; (2) every ascertainable name in the towns and villages alphabetically arranged under each county; (3) the names under each particular trade (in London and its suburbs) alphabetically arranged; (4) the names for the rest of England, Scotland and Wales similarly arranged; (5) the names for Ireland arranged under towns and trades; and (6) the names for the Channel Islands and Isle of Man also arranged under towns. It is claimed that the whole of the names given in the directory have been personally checked by the publishers' canvassers and their returns afterwards arranged by a staff of clerks specially trained to the work. The directory is published at 30s.

"Export Merchant Shippers' Directory."—We have received from the Carter Publishing Co., 116, High Holborn, London, W.C., a copy of the 1910 (45th) edition of this directory, which appears to have been carefully revised. The work is divided into two volumes, Vol. I. being devoted to London and Vol. II. to the provinces. In addition to the list of exporters, places of shipment and classes of goods shipped, and the lengthy alphabetical index to the class of goods shipped, &c., much useful information of a commercial and business character is given. To increase the utility of the book generally, and particularly of Vol. I. (London section), memo pages have been interleaved in the itineraries of the City. The published price of the directory is 15s. 6d. nett.

"Lloyd's Lawyer."—From "Lloyd's Weekly News," 12, Salisbury-square, London, E.C., comes a copy of "Lloyd's Lawyer: Legal Advice for All," which contains much information on legal points likely to arise in connection with current business affairs. A feature of the publication is that it contains particulars of nearly all recent Acts relating to industrial matters, including the Trade Boards Act, the Children's Act, the Labour Exchanges Act, Workmen's Compensation, Small Holdings and Old Age Pensions. As might be anticipated in a first edition of a book of this character, many important subjects are omitted, but no doubt a revised edition will include some of those. The work, which contains a great deal of information of general use, is published at the popular price of 6d.

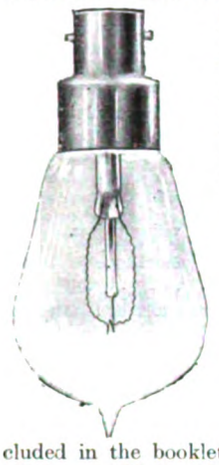
The Coming Holidays.—Modified as will probably be the holiday arrangements of many business men, owing to the course of public events, the busy man will still be interested in a publication which has been prepared for his special benefit to enable him to see at a glance the facilities which are offered on one of the best holiday routes in the kingdom—that of the London & South-Western Railway. The 12th annual official illustrated guide to the holiday and health resorts and show places on this extensive line has just been issued, and contains a large quantity of serviceable information and interesting illustrations of places in the United Kingdom, the Channel Islands,

Digitized by Google

Normandy and Britanny which are reached with easy facility and comfort by this company's trains and steamers. These particulars include no less than 115 golf courses, in convenient proximity, many hundreds of hotels, furnished houses and apartments, and other information which will save time and temper in the solution of the difficult annual problem "Where to spend a holiday." 50,000 copies of this guide have been issued, and it can be obtained free at any station on the L. & S.W. system, or from any of the company's agents at home or abroad.

CATALOGUES, &c.

One-watt Battery Lamps.—Messrs. Siemens Bros. Dynamo Works have issued a price list of one-watt battery lamps suitable for use on pressures between 2 and 16 volts. These lamps have filaments of drawn wire and an efficiency of about 1 watt per candle-power. Users of this type of lamp should apply to Messrs. Siemens for this list, as it contains full details whereby great reductions are obtainable when large quantities of these lamps are purchased. The accompanying illustration gives a good idea of the general appearance of the lamps.



Two-pin Plug.—Messrs. Marsh, Son & Co. have placed on the market a new two-pin plug whose special feature is its flatness.

Wire Ropes and Fittings for Mining.—Messrs. W. N. Brunton & Son have ready a new catalogue dealing with this subject. Included in the booklet are particulars likely to be of use to mine managers. Those of our readers interested in this branch of work should obtain a copy of the catalogue.

Siemens' Woolwich and Dalston Works.—From Messrs. Siemens Bros. & Co. comes a pamphlet in which a full and interesting description of the company's works at Woolwich and Dalston. The details are likely to be of considerable interest to our readers, as in the latter works Tantalum lamps are manufactured, and we propose to recur to the subject again.

Alternating-current and Induction Motors.—Messrs. T. Harding Churton & Co. forward an interesting pamphlet on this subject. The question is dealt with not only from a commercial, but also from a technical point of view, and the information given should be of service to intending purchasers of motors.

Sterling Telephones.—The Sterling Telephone & Electric Co. send a publication dealing with their common battery automatic intercommunication telephones.

Gearing.—A pamphlet from the Buffoline Noiseless Gear Co. informs us that the company are bringing out a new catalogue dealing with gearing for all purposes and with Buffoline pinions made by a special process.

Motor-starters.—The Braulik Engineering Co. have ready a new list of motor-starters, controllers, &c., and a list dealing with motors and dynamos.

Passenger Cars for Lifts.—Messrs. A. & P. Steven have published a catalogue showing their designs of wrought-iron and wood lift cars. The catalogue is amply illustrated throughout, and indicates that the range covered by the firm in their manufactures is a large one.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during April, 1910, and (*b*) during the current year from Jan. 1 to April 30, with the increases or decreases compared with the corresponding periods of 1909:—

Electrical machinery (*a*) £44,170 (increase £9,579), (*b*) £181,589 (increase £27,661); telegraph and telephone cables (*a*) £15,743 (increase £8,190), (*b*) £52,921 (increase £20,563); telegraph and telephone apparatus (*a*) £16,895 (increase £690), (*b*) £58,796 (decrease £1,731); other electrical wires and cables, rubber insulated (*a*) £12,987 (increase £8,914), (*b*) £49,227 (increase £31,205); with other insulations (*a*) £2,825 (decrease £5,148), (*b*) £8,894 (decrease £28,967); carbons (*a*) £10,545 (increase £658), (*b*) £46,291 (increase £226); glow lamps (*a*) £32,987 (decrease £10,082), (*b*) £172,954 (increase £11,283); arc lamps and electric searchlights (*a*) £125 (decrease £143), (*b*) £1,401 (decrease £6,229); parts of arc lamps and searchlights (other than carbons) £6,825 (increase £3,066), (*b*) £24,199 (increase £8,077); primary and secondary batteries (*a*) £4,384 (increase £310), (*b*) £13,841 (decrease £4,440). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £112,341 (increase £8,170), (*b*) £460,718 (increase £28,218).

Exports.—The exports of electrical machinery, material, &c., (*a*) during April, 1910, and (*b*) during the current year from Jan. 1 to April 30, and the increases and decreases compared with the corresponding periods of 1909, are as follows:—

Electrical machinery (*a*) £144,737 (increase £5,170), (*b*) £462,498 (decrease £11,667); telegraph and telephone cables (*a*) £60,896 (increase £13,406), (*b*) £804,136 (increase £658,402); telegraph and telepone apparatus (*a*) £17,126 (increase £1,451), (*b*) £52,480 (decrease £13,145); other electrical wires and cables, rubber insulated (*a*) £39,229 (increase £13,030), (*b*) £137,426 (increase £48,612); with other insulations (*a*) £32,443 (increase £12,426), (*b*) £79,131 (decrease £792); carbons (*a*) £1,612 (increase £1,204), (*b*) £6,190 (increase £3,719); glow lamps (*a*) £9,977 (increase £4,855), (*b*) £41,807 (increase £19,276); arc lamps and searchlights (*a*) £1,954 (increase £979) (*b*) £6,922 (decrease £142); parts of arc lamps and searchlights (other than carbons) (*a*) £1,162 (decrease £63), (*b*) £4,680 (decrease £1,614); primary and secondary batteries (*a*) £7,201 (decrease £767), (*b*) £33,570 (decrease £4,831). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £207,083 (increase £54,828), (*b*) £1,318,079 (increase £741,770).

BANKRUPTCIES, LIQUIDATIONS, &c.

The public examination took place last week of William Henry Palmer, electric light contractor, &c., formerly carrying on business in Great Castle-street, London, W.

In April, 1909, debtor sold his business to a company, which took over the assets, but not the liabilities, and he stated that he owed £1,070 to unsecured creditors and had no assets. Attributed his failure to trade losses and bad debts.

A first and final dividend of 3s. will be payable on May 23 (or subsequent Mondays and Wednesdays) at the offices of F. Nicholls White & Co., 14, Old Jewry-chambers, London, E.C., to creditors of C. H. W. Biggs (trading as Biggs & Sons), printer and publisher, 139 and 140, Salisbury-court, Fleet-street, E.C., and Glebe Lodge, The Glebe, Champion Hill, S.E., London.

A dividend is to be paid in respect of the separate estate of Joseph G. S. Cunnington, electrical engineer and contractor (lately trading with H. P. Allison, as Laing, Wharton & Cunnington, at 7, Great Newport-street, London, W.C.) Claims to Mr. A. Page, 28, King-street, Cheapside, London, E.C., by May 24.

A dividend is to be paid to creditors of Walter S. Jenkinson, electrical engineer, Rodborough, near Stroud. Claims to Mr. C. Scott, Station-road, Gloucester, by May 24.

A meeting to receive an account of the winding up of the Himalaya Electric Railway (Ltd.) will be held on June 10 at 28, Chapel-street, Liverpool.

The Failure of S. W. Hart.—*An Explanation.*—In reference to a paragraph appearing on p. 168 of our last issue we have received the following letter from the Hart Accumulator Co. (Ltd.):—

TO THE EDITOR OF THE ELECTRICIAN.

Sir: We wish to correct an erroneous impression that has arisen in some quarters in regard to the notice appearing in your issue of the 6th instant, relative to the meeting of creditors of Mr. S. W. Hart last Wednesday at the London Bankruptcy Court.

According to the report you publish it appears that Mr. Hart stated he was the inventor and patentee of the Hart Accumulator, and we wish to make it clear that there is no truth whatever in this statement of his, as the inventor and original owner of the "Hart" patents was our present engineer and managing director, Mr. E. J. Clark.

The matter is one which in no way concerns the position of our company, as although the name of Mr. Hart is associated with our own, this was only by reason of him being financially interested in one of our patents, and Mr. Hart has never taken any active part in the management, so that our business will not be affected in the slightest degree.

In regard to the debtor's statement that he attributed his failure to the depreciation in value of his shares, we fail to understand why this excuse should have been put forward, as our company has never been in a better position than it is to-day. From the date of formation of the company up to the present time our business has been steadily developing, and our works have been enlarged time after time to cope with the large demand that we have had to meet for our storage cells. We much regret that the name of our company has been brought by Mr. Hart into the matter of his bankruptcy, as there was not the slightest reason for him doing so, and as the report you publish only concerns the debtor's own private affairs we should be very glad if you will insert this explanation in your next issue to avoid any further misunderstanding.

The Hart Accumulator Co. (Ltd.),
Stratford, London, May 10. F. J. Holmes.

"The Inventions of Nikola Tesla."—"The Electrician" Co. have inquiries for copies of Mr. T. C. Martin's book, published about 1894, entitled "The Inventions of Nikola Tesla." Anyone desirous of disposing of copies of this book will please address the Publisher, 1, 2 and 3, Salisbury-court, Fleet-street London.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

February 14, 1910.

3,567 SNAGGE. Telephone receiver rest.
3,578 DUTTON & MCKENZIE & HOLLAND. Signalling and interlocking for railways and tramways. (Addition to No. 784 '09.)*
3,582 WALL. Call boxes for telephones and the like.
3,637 PATTERSON. Electric cab-controlling system for railways.*

February 15, 1910.

3,651 RUSHTON. Electric contacts for electric incandescent lamps and the like.
3,697 LUX. Electrically controlling valves. (Date applied for, 15/2/09.)*†
3,706 COMINGS. Packing incandescent electric lamps and similar frapile articles.
3,729 GUNNER. Shade carrier ring for electric lamp-holders and the like.
3,733 MARSEILLE & GOUIN. Manufacture of alkaline accumulator electrodes for preventing the dropping of active material therefrom. (Addition to No. 15,373/09. Date applied for, 8/3/09.)*†
3,756 CHISHOLM-ELLAMS. Facilitating the recording of telephone calls.

February 16, 1910.

3,802 CUNNINGHAM. Magneto-dynamo armatures.*
3,818 SIEMENS BROS. & CO. & DIESELHORST. Electric cables.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Co. (Ltd.)

The seventy-sixth ordinary general meeting of this Company was held on Wednesday, under the presidency of Sir JOHN WOLFE BARRY, K.C.B.

The SECRETARY (Mr. A. R. Hardie) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I feel sure that the stockholders at this meeting will like to take the opportunity, as a corporate body, of expressing to the Throne their sense of the great public disaster which has overtaken the nation in the death of our beloved Sovereign King Edward VII. It is a loss which is not only a public disaster, but which I think appeals to most of us—in fact, I may say to each and all of us—as a deep personal loss. The services of the late King were not confined to his own country and to the Empire over which he so well presided—they were really world wide, for the influence of his Majesty was felt in every part of the globe. I am, therefore, certain that the stockholders will feel with me that, as it happens we are assembled in general meeting just after the death of the King, a resolution should go from the meeting expressing not only their sense of the great public loss which has been sustained, but also of their profound sympathy with his Majesty, their Majesties the Queen and the Queen Mother, and with the other members of the Royal Family in their heavy bereavement. I, therefore, beg to propose the following resolution

"*That the stockholders of the Eastern Telegraph Co. in General Meeting assembled humbly beg leave to express to his Majesty the King their profound grief at the death of his illustrious and universally-beloved father King Edward VII., and to offer their respectful sympathy with his Majesty the King, their Majesties the Queen and Queen Mother, and with the other members of the Royal Family in their bereavement. The stockholders further ask to be allowed to express their profound and dutiful attachment to the Crown and their heartfelt sense of loyalty to his Majesty.*"

The MARQUESS OF TWEEDDALE seconded the motion, which was carried unanimously, all present upstanding.

The SECRETARY afterwards read the auditors' report.

The CHAIRMAN then said: Gentlemen, I am glad to say the directors are able to present a satisfactory report to the stockholders. The gross revenue for the half-year amounted, in round numbers, to £620,900, as against, for the corresponding half-year of 1908, £566,100, or an increase of £54,800. The income from messages and other receipts shows a satisfactory increase of £49,200, while interest on investments, &c., is £5,600 more than for the corresponding half-year. The improvement shown in our message receipts is spread over practically every branch of our traffic, and is largely attributable to business having reference to rubber and oil. It is, however, satisfactory to note that the receipts from traffic exchanged with South Africa show an increase of £10,000, while the receipts from traffic with India are £12,500 more than they were for the half-year to December, 1908. The South African traffic was not affected by the boom in rubber and oil, the improvement being due to commercial activity generally. On the expenditure side it will be seen that the expenses for the half-year amounted, in round numbers, to £250,500, as against, for the half-year ended December, 1908, £253,600, or a decrease of £3,100. The ordinary working expenses have increased by £2,500, while differences in exchange have adversely affected the comparison of the two half-years to the extent of £1,000. On the other hand, the item in the accounts under the heading of expenses attending maintenance of cables is £6,600 less than for the corresponding half-year, so that the nett result shows a decrease in the total expenses—as I have already stated—of £3,100. The actual expenses attending maintenance of cables show an increase of £4,300; but the amount received from foreign governments and other telegraph companies in respect of the charter of our cable ships is £10,900 more this half-year than in the half-year to December, 1908, the nett result being a reduction in the expenses of £6,600.

I referred at the last meeting to the operation that had been in progress for some time of gradually renewing the original Aden-Bombay cable. During the half-year a further 100 knots have been renewed, the cost of which, amounting to £10,676, has been charged as usual against the general reserve fund. There are about 220 knots of this No. 1 section still to be renewed. It has been decided to increase the reserve which has been made as a provision on account of the market fluctuations of our reserve fund investments, and a further £50,000 has accordingly been taken from the general reserve fund for this purpose, making a total provision on this account of £180,000. At the time this fund was originally created, the investments amounted to about £1,300,000, and a provision of about 10 per cent. on this amount was set aside. At the date of these accounts we have over £1,800,000 invested, and by increasing this provision to £180,000 the Board is continuing the principle adopted and generally approved in 1907. I think the nett result of the year's working may be considered satisfactory, as we have been able to carry £70,000 more to the general reserve fund than we did in 1908, while maintaining the payment of the usual dividend and bonus of 7 per cent.

Referring to the paragraph in the report on the subject of an extended news service, the Associated Companies have long been anxious to make some special arrangement whereby a considerable addition to the volume of British Imperial news might be distributed throughout the whole of the Empire, so that our colonies and dependencies might be more in touch with the facts and ideas of the mother country. You may remember that a substantial reduction in the rates of ordinary press messages exchanged with India, South Africa, Australia and many other places was brought into operation in August last year, and these rates remain in force, and are all in the above direction of greater inter-communication. But to attain more fully the special object which we had in view, it was necessary to make some arrangement by which the press conveying the news to the public through the medium of their publications should be allowed to send a greater number of words without addition to the contribution hitherto made by them.

It was not an easy matter to bring about a practical scheme acceptable to everyone, but I am glad to say that after much consideration and consultation with those interested in this important matter, we have been able to begin a service by arrangement with Reuter's Company. The arrangement enables that agency to have the distribution of 150,000 words per annum of Imperial news at Aden, which place is *en route* to all the Eastern colonies and dependencies of Great Britain. On the way to Aden the news is also made use of to supply Gibraltar, Malta, and Egypt. It is sent on to South Africa, and used *en route* for Zanzibar, Uganda, Seychelles and Mauritius. From Cape Town it is telegraphed to the British colonies on the West Coast of Africa. At the present time, part of the news is sent on for distribution from Aden to India, and is available for distribution amongst the Indian newspapers. We hope that in a very short time arrangements will be made with the Indian Government whereby the public in India may have the benefit of the whole of the increased service. Negotiations are still in progress, and we hope that before very long the British colonies of the Straits Settlements and Hong Kong will also receive the additional news, and similar negotiations are being carried on for the extension of the service to Australasia. I now move the adoption of the report and accounts, and the payment of the dividends and bonus set out therein.

The VICE-CHAIRMAN and MANAGING DIRECTOR (Sir John Denison-Pender, K.C.M.G.) seconded the resolution, which was carried unanimously.

A hearty vote of thanks to the Chairman, Directors and staff for their able administration of the Company's affairs was then carried unanimously, and the proceedings terminated.

Eastern Extension Australasia & China Telegraph Co. (Ltd.)

The seventy-third ordinary general meeting was held on Tuesday, under the presidency of Sir JOHN WOLFE BARRY, K.C.B.

The GENERAL MANAGER (Mr. F. E. Hesse) read the notice convening the meeting and the auditors' report.

The CHAIRMAN said: Ladies and gentlemen, we meet to-day under the shadow of a great national bereavement and disaster in the death of King Edward, who was a monarch revered and appreciated by the whole country, and, I may say, by every civilised nation—a monarch whose wise judgment and profound political wisdom, combined with a personal interest and sympathy with the highest and lowest of his subjects, were most remarkable. His high qualities were and are highly appreciated by one and all, so that each one of us feels his death to be not only a public disaster, but also a deep personal loss. I feel sure that the meeting will wish to record its sense of loss, its sympathy and condolence with the King and the Royal Family, and its attachment and loyalty to the Crown; and therefore I wish to move for the acceptance of this meeting—"That the shareholders of the Eastern Extension Australasia & China Telegraph Co., in general meeting assembled, humbly beg leave to express to his Majesty the King their profound grief at the death of his illustrious and universally beloved father King Edward VII., and to offer their respectful sympathy with his Majesty and the Royal Family in their bereavement. The shareholders further ask to be allowed to express their profound and dutiful attachment to the Crown and their heartfelt sense of loyalty to his Majesty." (Hear, hear.)

The MARQUESS OF TWEEDDALE, K.T., seconded the resolution, which was approved by all present upstanding.

The CHAIRMAN (continuing) said: Turning now to the accounts, when I last addressed you I mentioned that the commercial depression which had prevailed in the Far East for some considerable time, and had adversely affected our traffic receipts, appeared to be at last passing away. The improved report and accounts now before the meeting show that the views I then expressed were justified, and I am happy to say the present outlook appears to be still encouraging.

Dealing with the revenue, you will find that the figures for the past six months show that the gross receipts amounted in round numbers to £315,000, against £307,000 for the corresponding period of 1908, showing an increase of £8,000. The actual result, however, is better than these comparative figures indicate seeing that £15,000 of exceptional revenue in connection with the Tasmanian cables was included in the accounts for 1908 which does not appear in the present accounts; consequently, if this exceptional revenue were left out of the comparison, the receipts would show an increase for the half-year of roundly £23,000. The working and other expenses amounted in round numbers to £143,000, against £151,000 for the corresponding period of 1908, showing a decrease of £8,000, which is principally due to the expenses attending the maintenance of our cables having been considerably less during the past six months than in the same period of the previous year. Comparing the figures for the whole year, the results are as follows:—Gross receipts amounted to £606,000 for 1909, against £597,000 for 1908, or an increase of £9,000. The expenditure amounted to £337,000 for 1909, against £339,000 for 1908, showing a decrease of £2,000. Thus, in spite of the depression in the first half of 1909 the net result of the past year's working was £11,000 better than in 1908. The net profit for the half-year was roundly £152,000, and, after adding nearly £59,000 brought forward from the previous half-year, there remained an available balance of £211,000.

Digitized by Google

The usual quarterly interim dividends of 2s. 6d. per share were paid during the past year, and it is now proposed to distribute a final dividend for the year of like amount, making a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution for the year 1909 of 7 per cent. on the share capital. The usual additions have been made during the past year to the maintenance ships', insurance, and depreciation funds, and, after applying £50,000 of the revenue balance to the general reserve fund, the sum of £26,000 is carried forward, or £8,000 more than in the corresponding period of 1908, when £18,000 was carried forward. I now move the adoption of the report and accounts, and the declaration of the dividend and bonus set out therein.

The MARQUESS OF TWEEDDALE seconded the resolution, which was carried unanimously.

Resolutions re-electing the retiring Directors (the Marquess of Tweeddale, K.T., and Sir John Wolfe Barry, K.C.B.) and the auditors were then carried, and a cordial vote of thanks to the Chairman, Directors and staff brought the proceedings to a close.

Western Telegraph Co. (Ltd.)

The seventy-third ordinary general meeting was held on Wednesday, under the presidency of Sir JOHN WOLFE BARRY, K.C.B.

The SECRETARY (Mr. E. Steer Hodson) read the notice calling the meeting and the auditors' report.

The CHAIRMAN then said: Gentlemen, before proceeding to the regular business of the general meeting, I feel quite certain that the stockholders of the Western Co. will like, as they are assembled at this sad time, when we are all mourning the death of our King, to approach the Throne with some resolution of sympathy, condolence and loyalty. The Eastern and the Eastern Extension Companies have both adopted a resolution and I shall ask you to make it your own, so that all the three companies —the Associated Companies—can send a resolution in the names of themselves individually and collectively. A resolution similar to that submitted to the meetings of the Eastern Extension and Eastern Telegraph Companies (set out on page 213) was then proposed by the chairman, seconded by the deputy-chairman, Sir John Denison-Pender, K.C.M.G., and approved on behalf of the shareholders by Mr. George Ennis, and carried unanimously.

The CHAIRMAN (continuing) said: We submit to-day a report and statement of accounts which we think you will consider satisfactory. The receipts from messages compared with the corresponding half-year show an increase of £43,408, and from other sources £4,428, together £47,836. All classes of telegraphic correspondence with South America and West and South Africa contributed to the improvement in our revenue, and I am pleased to say that the prospects for the current half-year are of a gratifying character. We are committed to a reduction in the tariff on June 1 next with South America, which will entail a considerable loss of revenue unless the traffic increases proportionately.

With regard to the general and other expenses, those incurred in London were more by £183; at the stations abroad they were increased by £5,683; the cost of maintaining the cables was more by £2,604; income tax shows an increase of £1,897, the four sums making a total of £10,367. Against this, however, there was a net reduction of the amount of other items due chiefly to expiration of royalties and reduced expenses in connection with improved apparatus for cable working at the stations. This decrease amounted to £1,121, making a net increase in expenditure of £9,246. An analysis of the accounts shows that the increase in salaries and wages and cost of training staff is due to annual promotions and to an increase in the number of the men employed required for our growing traffic. Travelling, house allowances and contributions to the pension fund were also consequently higher. We have also had to fit up new and larger offices at four stations and increase the staff quarters at another, causing an increase in the repairs and renewals of furniture account. Larger sums were spent on agencies, advertising, postage, office expenses and bankers' commission in connection with the increased revenue. Decreases are shown in the cost of the maintenance of our landlines, repairs to buildings, medical expenses, and one or two other items. First and second interim dividends, amounting to £62,379, have been paid, and after transferring £155,000 to the general reserve fund, and £10,000 to the land and buildings depreciation fund, there remains a balance of £6,008, which is carried forward to the next account.

The new cable referred to by me at the general meeting last November between the Island of Ascension and the River Plate has been successfully completed; the expenditure upon it has been met mainly out of our reserve fund and partly by the issue of debenture stock under the powers vested in the Board by the articles of association of the Company. In connection with the Argentine direct cable the Board are now considering the question of strengthening the means of communication in other parts of the Company's system. I now move the adoption of the report and accounts.

The DEPUTY-CHAIRMAN seconded the motion, which was carried unanimously.

Mr. J. BULL asked if the Chairman had any reason to alter the opinion which he had expressed at former meetings with regard to wireless telegraphy.

The CHAIRMAN replied that nothing had occurred up to the present to alter his general view, that for a service of telegraphy, except for ships, the cable had such advantages that it would always beat any system of wireless telegraphy. The great utility to his mind of wireless telegraphy was in the communication with ships, which could not, of course, be served by cable. He looked forward to still greater benefits and greater development in the communications between the land and ships and between ships and ships, but as far as anything they knew at present, for quickness, certainty and secrecy there was no comparison between the service given by a cable and that given by any system of wireless telegraphy.

A cordial vote of thanks was then passed to the Chairman, the Directors and the staff, and the proceedings terminated.

West African Telegraph Co. (Ltd.)

The twenty-fifth ordinary general meeting was held on Wednesday under the presidency of the MARQUIS OF TWEEDDALE, K.T.

The SECRETARY (Mr. John Cambrook) read the notice calling the meeting.

The CHAIRMAN referred feelingly to the sad circumstances under which they met, and a resolution of sympathy with the Royal Family was carried unanimously.

The CHAIRMAN then said: There is little in the accounts to which, I think, special attention need be drawn. Gross revenue for 1909 amounted to £59,000, against, for the year 1908, £56,300, or an increase of £2,700, due principally to our increased receipts from the South African joint purse. Interest and dividends on reserve fund investments are increased by £500. The working expenses for the year amounted to £22,200, against, for the year 1908, £24,800, or a decrease of £2,600. This is explained by the fact that the general expenses at stations show a reduction of about £800, while the expenses attending maintenance of cables are £1,600 less than they were for the previous year. Other items in the revenue account also show small decreases. The net result for the year is a profit of £36,800 (against £31,500 last year), which, with the balance brought forward from last year, enables us to make a substantial contribution to our reserve fund, and to pay the same dividend of 4 per cent., which has been declared for the last few years. The new staff quarters at Bolama, to which I referred at the last meeting, have been completed during the year, and the balance of the cost has been charged against the general reserve fund. I now move the adoption of the report and accounts.

The MANAGING DIRECTOR (Sir John Denison-Pender, K.C.M.G.) seconded the motion, which was carried unanimously.

The retiring director (Mr. Robert Kaye Gray) and the auditors were then re-elected, and a vote of thanks to the chairman, directors and staff brought the proceedings to a close.

West Coast of America Telegraph Co. (Ltd.)

The thirteenth ordinary general meeting was held on Tuesday, Sir JOHN DENISON-PENDER, K.C.M.G., presiding.

The SECRETARY (Mr. Fredk. L. Robinson) read the notice convening the meeting, and the auditors' report.

The CHAIRMAN, after feelingly referring to the illness and death of King Edward, said: I think the accounts and report leave very little for me to say, but there are one or two points on which, perhaps, you may like further information. As regards the traffics, they are £2,000 down. That is not a very serious matter, and really comes from a falling-off in the local traffic—the through traffic has been good—and from the cable being down in the year under review for 67 days against 57 in the preceding 12 months. That, of course, means that during the period of interruption there was a very considerable reduction of traffic, and the opposition got the business which would otherwise have gone over our line. But, unfortunately, when you look at the expenses you find that they are £6,000 up. In 1908 the expenses reached the sum of £33,200, whereas in 1909 they were £39,200. An increase of £6,000 looks a very considerable item on such a figure as £39,000, but I think that when I have explained the various items you will see that a great deal of it is entirely satisfactorily accounted for. First of all, you have the allowances on the coast which we have had to give, as living has become dearer. You have the increased value of the Chilian currency, which also makes a considerable difference to us. Then you have the usual things that we have at home—rent, rates, taxes and travelling expenses—and also, not a very considerable item, but still everything helps to mount up, we have had to open an agency at La Paz, in Bolivia. The increases in these items which I have mentioned come to £2,000 out of the £6,000. Cable work is not like manufacturing, where, when you have not the work to do, you can reduce your staff. In cable work you must keep your staff. A great many of the clerks are sent from England, and the local men have to be retained. Therefore, whether you have heavy traffics or not the staff charges remain pretty much the same. I have accounted for £2,000 out of the increase of £6,000. With regard to the remaining £4,000 it is really due to an increase in the cable repairs. The repairs have cost us considerably more because the ship spent 10 days longer at the work than in the previous year, and the amount of new cable put in has been considerably more. That is a charge which I have always said should not be, in my opinion, included in the general expenses, because we may assume that if we put in more cable one year we have taken out bad cable and have given that portion of the cable a new life. Therefore, we may hope that if we have an excessive charge for cable maintenance one year we shall get a relief in future years, so that if we could manage it—but I think it would be a very difficult thing—the cable repairs should be spread over a period of years. Then in 1908 you will remember we received £1,500 for the charter of our steamer. In the past year the steamer was not chartered. Consequently we are minus that sum, and that makes the comparison rather an unfair comparison with the preceding 12 months. The only new matter really that I can put before you this year is the new steamer which I referred to at the general meeting held last May. We had to replace the old steamer, which was 31 years old, and this new steamer delivered on your station has cost, roughly

Digitized by Google

speaking, just under £20,000. We wrote down the old steamer in our books some years ago to £10,000. We received £3,000 for her when she was sold the other day, leaving a loss on that of £7,000. But I am glad to say that during the latter years we had raised a sum of £12,000 as "steamer depreciation fund," and therefore the cost of the new steamer will be, to a certain extent, reduced. At £20,000 she is not at all an expensive boat. She is doing her work well, she is a much steadier ship than the last one, and in every way I think she will prove to be a more satisfactory boat. I may also mention that when we send out cable to the coast we have to do so in tanks, and put it in a chartered steamer, or at any rate we had to get space in an ordinary commercial steamer, but the new steamer carried out that cable and so saved us in that way £2,100, which really goes in reduction of her cost. I do not think there is anything else to refer to, and I move the adoption of the report and accounts.

Sir ALBERT J. LEPPOC CAPPEL, K.C.I.E., seconded the motion, and it was agreed to unanimously without discussion, as was a resolution approving the dividend of 2½ per cent. (tax free).

The retiring director (Mr. Alexander Johnston) and the auditors were then re-elected, and a vote of thanks to the Chairman brought the proceedings to a close.

West India & Panama Telegraph Co. (Ltd.)

The sixty-sixth ordinary general meeting was held on Wednesday, Mr. WALTER BISHOP KINGSFORD presiding.

The MANAGER and SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the auditors' report.

The CHAIRMAN said: Gentlemen, our total receipts for the half-year amounted to £34,678. 12s. 1d., or only £193 short of those with which we are comparing. On the expenses side the total expenditure (£23,557. 18s. 6d.) is £1,398 more than that for the corresponding period. Of the increased expenditure of £1,398 no less than £1,300 is in connection with expenses attending repairs to cables. Nearly £800 of this is accounted for by our repairing steamer having been engaged for 97 days during the half-year, as compared with 63 days in the corresponding period, whilst the sale of old core, &c., realised about £500 less than it did in the corresponding half-year. The directors have charged revenue with £7,980. 14s. 7d. in respect of the normal expenses of repairing our cables, but the sum of £2,414. 8s. 11d., representing the cost of 33 knots of new cable laid in on special repairs to the Jamaica–San Juan and the St. Kitts–Antigua sections, has been charged to reserve account. At our last meeting I spoke of the exceptionally severe storms and floods which prevailed in November throughout the West Indies, and especially in Jamaica and Hayti. Two of our main cables landing in Jamaica were broken, thus cutting off communication for several days with all of our stations east of that island. Our cable between Jamaica and Colon was also interrupted during nine days from the same cause. Of course, these abnormal interruptions served to keep our repairing steamer very fully employed. Hence the increased expenditure. The storms and floods also badly damaged our land lines in Jamaica, and the repair of these cost us nearly the whole of the £268, the extra outlay shown under "Maintenance of land lines." As the result of the half-year's working, inclusive of interest and the amount brought forward from last half-year, there remains an available balance of £13,310 to be dealt with. I am very glad to tell you that the traffic receipts for the current half-year to the end of April show a satisfactory increase. I now move the adoption of the report and accounts and the payments therein set out.

Mr. HENRY HOLMES seconded that resolution, which was carried unanimously.

The retiring director (Mr. W. B. Kingsford) and the retiring auditors were then re-elected, and a very cordial vote of thanks to the chairman, directors and staff of the company brought the proceedings to a close.

Submarine Cables' Trust.

The thirty-ninth ordinary annual meeting was held on Tuesday, the MARQUESS OF TWEEDDALE, K.T., in the chair.

The SECRETARY (Mr. Sidney Collett) having read the notice calling the meeting,

The CHAIRMAN, after referring to the sad death of King Edward, said the revenue for the year to April 15 amounted to £25,259. Deducting working expenses and adding £228 brought forward, the available balance was £24,328, against £24,315 in the previous year. We have paid the usual half-yearly coupons at the rate of 6 per cent. net (absorbing £17,952), and with the surplus we have acquired 52 certificates, *ex* the coupon of reversion. This is the largest number of certificates we have ever acquired with the surplus funds of the Trust in any year, and absorbed £6,201, leaving £175 to be carried forward. We have now acquired and cancelled 1,260 out of the original 4,200 certificates. There have been some re-arrangements of our capital during the year, and our securities show an appreciation over original cost of £181,980. I now move the adoption of the report and accounts.

Sir JOHN DENISON-PENDER, K.C.M.G., seconded the resolution, which, after a brief discussion, was carried unanimously.

The re-election of Messrs. Deloitte, Plender, Griffiths & Co. and Messrs. Gane, Jackson, Jefferys, Wells & Co. as auditors was then approved, and a vote of thanks to the chairman and his co-trustees brought the proceedings to a close.

BRITISH WESTINGHOUSE ELECTRIC & MFG. CO. (LTD.)—At the meeting on Monday the chairman (Mr. J. Annan Bryce, M.P.) said that though they were not able to show a profit on the past year's working, the figures showed a distinct improvement, compared with 1908. In regard to their holdings in other companies these represented holdings in the Clyde Valley Power Co.'s shares (about £200,000), Traction & Power Securities Co.'s shares (about £50,000) and Mersey Railway 4 per cent. debenture stock (about £30,000). The last security had considerably improved in value since the line was electrified, and it was now apparently earning its 4 per cent. interest on these debentures. The Clyde Valley Co. had turned the corner and was beginning to make profits, so that the directors had reason to hope that the value placed upon that security (its cost to the company) would eventually be realised. The Traction & Power Securities Co. shares had improved somewhat since last year, due to the improved position of the Mersey Railway and Clyde Valley Companies, in which they held large interests. He was glad to be able to say that, notwithstanding a most unpropitious year, the falling off in the amount of orders, compared with 1908, was only about 6½ per cent. It was particularly satisfactory to observe that the export business continued to expand, and all means were being adopted to develop that side of their operations, especially in the British possessions. They were continuing to cultivate friendly relations with the foreign Westinghouse companies, in conjunction with whom they were, and had been, doing a fair amount of business abroad. Competition had continued to be as severe as ever, and manifestly if there was only enough business to partially fill the works of manufacturing companies, there must inevitably result a cutting of prices; while they were specially handicapped by having works much too large for the amount of business offering. Paucity of orders led to demoralisation in prices under conditions of over-production, and they could only wait for revival in trade and the natural growth of the electrical business, meanwhile carefully fostering economy in all branches of the business. There were distinct signs of improvement in the volume of business.

CALCUTTA ELECTRIC SUPPLY CORP. (LTD.)—During 1909 7,856,383 units of electricity were sold, compared with 6,765,792 units in 1908. The number of houses connected was 5,078, against 4,396, and the equivalent connections in 8 c.p. lamps show an increase of 73,437 (from 378,835 to 452,272 8 c.p.). A considerable demand has arisen in the northern districts of Calcutta for electrical energy for power, and in order to meet this, and at the same time to economise the cost of production, it was proposed to erect a large h.t. generating station at Cossipore. Mr. Jenkin (of Sir Alex. Kennedy & Jenkin) has visited Calcutta to advise the board, and on his recommendation it has been decided to place at once some additional plant in the Ultadangha station of the company. Sir Alex. B. W. Kennedy has been appointed consulting engineer to the company. The net profit amounted to £67,023. 14s. 11d. (compared with £58,188. 0s. 4d.), and after adding balance forward (£3,303. 13s. 8d.) and deducting interim dividend at rate of 6½ per cent. on the ordinary shares, and the preference dividend, &c., the available surplus is £46,134. 5s. 11d., compared with £41,668. 13s. The directors recommend that £17,000 be placed to depreciation and renewals account, and a final dividend at the rate of 9½ per cent. on the ordinary shares (making 8 per cent. for the year), leaving £5,492. 1s. 3d. to be carried forward. There is no diminution in the applications for current, additional connections equivalent to 73,437 8 c.p. lamps having been made during last year, compared with 57,972 in the previous year.

CALLENDER'S CABLE & CONSTRUCTION CO. (LTD.)—The directors' report for 1909 states that the balance at credit of profit and loss account is £54,362. 5s. 9d., and, with £45,884. 10s. 7d. brought forward, the total is £100,246. 16s. 4d. Deducting debenture interest and preference dividend (£23,500) and appropriation for depreciation of buildings, plant and machinery (£8,294. 6s. 6d.), the available balance is £68,452. 9s. 10d. It is proposed to pay an ordinary dividend of 10 per cent., less tax (10s. per share whereof 5s., less tax, has been paid), absorbing £17,000, a bonus of 5s. per share (less tax) (£8,750), leaving £42,202. 9s. 10d. to be carried forward. The value of business done during 1909 showed a considerable reduction compared with recent years. The quantity of work available was even less than usual, and the struggle for orders was consequently severe, especially in the home trade. It is, therefore, with considerable satisfaction the directors notice the improvement in trade which has taken place since the beginning of the year, with the consequent increase in orders which have been placed with the company. The Anchor Cable Co. has again done well, and in spite of the extraordinary rise which has taken place in the price of rubber has been able to show even better results than in 1908.

COMPAGNIE BELGE DE TELEGRAPHIE SANS FIL (MARCONI SYSTEM). The "Financial News" states that at a meeting of this company on May 5 dividends of 50fr. on the ordinary shares and 24fr. on the founders shares were voted. The net profits for the past year were 47,229fr., against 26,706fr. in 1908. The increase in net profits is attributed to the daily paper the "Atlantic Daily News," which appears on all vessels of the principal French, German and Dutch steamship lines.

CRAIGPARK ELECTRIC CABLE CO. (LTD.)—At the meeting last week Mr. W. S. Brown, who presided, said that they were now in a very satisfactory position, having lost nothing in contracts through the rise in rubber. During the first few months of the year, owing to the appreciation in rubber, they barely made ends meet, but the latter part had witnessed a distinct improvement, and they were now in a sound position.

DELHI ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—At the meeting last week Col. Sir Buchanan Scott said the loss for the past year was £3,225, after charging debenture interest. The result was principally due to the low receipts from the tramway section during the winter months of 1908. The Diesel oil engine and other plant had arrived at Delhi, and its erection was nearly completed. The total cost of that extra plant was approximately £5,000. A satisfactory agreement had been made with Delhi Municipality for lighting Delhi for three years,

Digitized by Google

and the directors were in negotiation with a department of the Government of India for a large amount of lighting.

DUDLEY, STOURBRIDGE & DISTRICT ELECTRIC TRACTION CO. (LTD.)—The directors reported at the meeting last week that the gross receipts for 1909 amounted to £44,357. 19s. 11d. Deducting expenses, including repairs and maintenance, placing £2,000 to renewals and increasing depreciation accounts by £997. 14s., there remains £6,875. 3s. 5d. Deducting preference dividend, and adding £136. 19s. 5d. brought forward, £2,012. 2s. 10d. remained available, and the directors recommended a dividend of 2 per cent. on the ordinary shares. Expenditure on capital account during the year amounted to £1,339. 17s. 4d. This account has been credited with £49,567. 14s. 3d., of which £49,505 represents the purchase price of the tramways and light railways in Dudley. The purchase of these lines by the Corporation has been completed and have been leased to the company for 30 years from Jan. 1, 1909. An arbitration is pending to determine the price to be paid by the company to the Corporation for electrical energy for the next five years. It is expected that the order authorising the transfer of the Smethwick Electric Lighting Order (1898) from the Birmingham & Midland Tramways to the Shropshire, Worcestershire & Staffordshire Electric Power Co. and the sale to the power company of the generating stations at Harts Hill, Amblecote and Lye will be obtained and the sale carried out in the course of the present year. The parcels and goods service has given satisfactory results.

ELMORE'S GERMAN & AUSTRO-HUNGARIAN METAL CO. (LTD.)—The directors' report for 1909 states that the position of the Metall Co. has improved. The weight of goods sold shows an increase of 243 tons. The large amount of freight which the company has now to handle has necessitated the installation of a railway siding, while the increased business required the erection of a large building for storage as well as bunkers for coals. A powerful hydraulic push bench has been erected, which has increased the speed in the production of the large sizes of copper tubes at a reduced cost. The home trade was not good during the year, and a large proportion of the sales was for export; the average selling price received was, therefore, less than in previous years, with the result that, notwithstanding increased sales, the net profit is very little larger. Owing to increased output the cost of production has been still further reduced. Although the dividend receivable from the Metall Co. is 10 per cent., against 9½ per cent. last year, the amount standing to credit of profit and loss is not sufficient to permit of a dividend being declared on the company's shares.

At the meeting on Wednesday the report and accounts were adopted on the motion by the Chairman, Mr. John MacFarlan.

GRAVESEND & NORTHFLEET ELECTRIC TRAMWAYS (LTD.)—The total revenue for 1909 was £11,280. 3s. 1d., compared with £11,207. 0s. 7d. for 1908. Profit was £1,113. 12s. 7d., compared with £788. 0s. 5d., and available balance is £1,173. 9s. 3d. In view of the exceptional expenditure incurred in litigation in regard to the metering of the current supplied by Gravesend Corporation, the directors recommend that this amount be carried to reserve. The directors have under consideration the question of appeal against the decision of the High Court in January last, or, in the alternative, of resorting to arbitration if they fail to obtain a fair allowance by friendly negotiation.

JOHNSON & PHILLIPS (LTD.)—Mr. R. W. Blackwell presided at the meeting on Wednesday and said that during the past year the company's business had improved to a certain extent. It had not, of course improved to the extent desired, but they had made a profit for the year over and above that of the preceding year of £5,322. It was the expectation and hope of the directors that the past year would turn out much better. It was, however, the case that for the last four to five months of the year practically all orders seemed to cease, and business was practically at a standstill. He thought that had been the case in almost every concern which had anything like a similar business to themselves. Of course, orders being slow, competition was much greater, and the business that was taken during the year was taken at prices which were distinctly low throughout, while both copper and rubber were ruling exceedingly high. During the five years of thee ompany's existence they had set aside for depreciation on machinery and plant £18,200, and they had redeemed debentures to the extent of £20,390. Under those circumstances it seemed that it was unnecessary that a special fund should be written off this year for depreciation. Things were looking fairly well for the present year. They were busier in the shops than they had been for a long time past, and they sincerely hoped that the profit for the present year would be greater than it was last year.

The report and accounts were adopted, and Messrs. W. Claude Johnson and Thos. Dence were elected directors.

RANGOON ELECTRIC TRAMWAY & SUPPLY CO. (LTD.)—At the meeting on Monday Mr. Frank Tobin said that the company had made very considerable progress. The ordinary shareholders would receive a small dividend (3 per cent.), and he hoped this was an earnest of better things to come. The most important and satisfactory branch was the tramway, which had vastly increased its takings. In regard to public lighting, there was little to be said; all had worked smoothly with the municipality. The demand for private lighting and power was beginning to grow rapidly. They had ordered a turbine larger than any they had hitherto used. They had made a contract for the supply of coal for the next two years at a figure which would show a very appreciable economy on that they had been used to up to the present.

WOLVERHAMPTON DISTRICT ELECTRIC TRAMWAYS (LTD.)—At the meeting last week the directors reported that the total revenue for the year 1909 amounted to £22,851. 3s. 1d. Deducting expenses (including debenture interest, repairs and maintenance) and providing £500 for renewals, left a profit of £64. 19s. 11d., making, with £197. 13s. 6d. brought forward, £262. 13s. 5d., which the directors recommend should be carried forward. The capital outlay amounted to £1,132. 19s. 8d. Capital account has been credited with the proceeds of the sale to Dudley Corporation of the lines and equipment in Dudley, and the cars allocated to those lines. The purchase by Dudley Corporation of the company's tramways in Dudley has been completed, and the purchase price received. The falling off in traffic receipts is attributed to the bad weather and to the severe depression in trade. The parcels and goods service has given satisfactory results.

NEW COMPANIES, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

BRITISH ELECTRIC AUTOMATIC MACHINES (LTD.) (109,404.)—Reg. May 3, capital £150,000 in £1 shares (25,000 preferred), to aquire, deal with and turn to account any invention relating to automatic postage, ticket vending and printing machines, automatic letter boxes, automatic stamp affixing and registering machines, and any invention relating to postal or railway appliances, &c. First directors, N. Von Nettelbladt, Capt. J. P. Wood and H. Limbeer. Reg. office, Caxton House, Westminster, S.W.

FRENKEL'S ILLUMINATED SIGNS (LTD.) (109,072)—Reg. April 21, capital £500 in 475 preference shares of £1 each and 500 ordinary shares of 1s. each, to acquire a licence granted to L. S. Levy by the Reflector Synd. and to carry on the business of manufacturers of and dealers in illuminated advertising signs, and to adopt an agreement with J. Frenkel & Co. Private company. Reg. Office, Basishaw House, Basinghall-street, London, E.C.

GARRETT, HUNT & CO. (LTD.) (109,995)—Reg. April 19, capital, £2,000 in £1 shares, to take over the business of electrical engineers and contractors carried on by C. W. Garrett and G. T. Hunt, as Garrett, Hunt & Co. Private company. First directors, C. W. Garrett, G. T. Hunt, and C. J. W. Daniels. Reg. Office, 181, High-street, Lewisham, S.W.

HILL & HARRINGTON (LTD.) (108,963)—Reg. April 18, capital £2,000 in £1 shares, to take over the business carried on as Hill & Harrington, and to carry on the business of electrical and mechanical engineers, contractors, &c. Private company. First directors, J. Harrington and G. R. Barham. Reg. office, 41, Berners-street, London, W.

W. F. PEARE (LTD.) (3,557.)—Reg. in Dublin April 21, capital £10,000 in £1 shares, to acquire business of an electrical engineer carried on by W. F. Peare at Waterford. Private company. First directors, Sir W. G. D. Goff and H. W. D. Goff. Reg. office, 3, Catherine-street, Waterford.

MORTGAGES AND CHARGES.

ACKROYD & BEST (LTD.)—Issue on April 14 of £1,450 debentures, part of a series of which particulars have already been filed.

BERRY CONSTRUCTION CO. (LTD.)—Particulars of £2,000 debentures, created April 11, has been filed, the whole amount being now issued. Property charged, company's undertaking and property, present and future, including uncalled capital. No trustees.

FERABIN LAMP & ELECTRICAL ACCESSORIES (LTD.)—Particulars of £2,500 debentures, created May 4, have been filed, the whole amount being now issued. Property charged, certain patent relating to galvanic dry cells and any other patents which the company may become entitled relating thereto under an agreement dated Jan. 28, 1910. No trustees.

RECEIVERSHIP.

MUNSTER ELECTRIC LIGHTING CO. (LTD.)—A notice of the appointment of R. H. Bindloss, 26, North John-street, Liverpool, as receiver, on May 2, 1910, under powers contained in debentures dated Oct. 1 and Dec. 27, 1909, has been filed.

CITY NOTES.

MEMORANDA (May 12).—Bank rate 4 per cent. (since March 17, 1910). Price of silver, 24⅛d. per oz. Consols 81⅝—81¾ for money; 81⅞-82 **for account. Consols Pay Day, June 1; Stock and Shares Continuation Days, May 25 and June 8; Ticket Days, May 25 and June 9; Pay Days, May 27 and June 10; Mining Shares Carry Over Day, May 24.**

PRICES OF METALS (London).—*Copper*, **cash,** 56¾; **three months,** 56⅝. *Lead*, English, 12¾—13¼; foreign, cash, 12⅝; three months, 12¾. *Spelter*, 21⅞—22⅛. *Tin*, English, 143—150; foreign cash, 150; **three months,** 152. *Iron*, Cleveland, cash, 50/-, and **three months,** 50/11.

CENTRAL ELECTRIC SUPPLY CO. (LTD.)—The 4 per cent. guaranteed debenture stock transfer books of this company will be closed from 18th to 31st inst. inclusive.

CHLORIDE ELECTRICAL STORAGE CO. (LTD.)—A dividend at the rate of 6 per cent. upon the preference shares has been declared. In future the company's financial year will end March 31 instead of June 30.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted a quotation to £300,000 5 per cent. first debentures of the *Manaos Tramways & Light Co. (Ltd.)*. The committee have been asked to allow a further issue of $1,500,000 7 per cent. cumulative preference stock (in shares of $100) of the *Mexican Light & Power Co. (Ltd.)* to be quoted.

NOTES.

Diversity Factor.

APART from economies in running and in first cost due to the use of plant of large capacity, an electricity supply undertaking has the advantage, as against private installations, of a large diversity factor, due to the maximum demands of the various classes of load, and also of individual consumers, occurring at different periods throughout the day. The fixed charges on the necessarily large expenditure on mains may in many cases be sufficient entirely to counteract any economies in generation, but it is to the diversity factor that electricity supply undertakings must look to a large extent to obtain any economy over independent plants. In this connection we may mention some figures relating to the Commonwealth Edison Co., of Chicago, given in a recent issue of the "Electrical World." These seem to indicate that for private houses the diversity factor is 6·25, for commercial lighting 2·3, for a scattered motor load 2·5, and for large lighting or motor installations 1·4. In each case the ratio between the sum of the maximum demands of individual consumers and the actual maximum demand recorded at the generating station is given, and the figures will, doubtless, prove of interest to engineers in this country, as owing to the smaller use which is now being made of maximum demand indicators it is becoming more difficult to obtain particulars of this kind. The figure for residential consumers given above is very striking, a very much smaller figure being usually adopted. The difference is, perhaps, accounted for by the much greater use made of apparatus for electric heating and cooking in Chicago, this, of course, being likely to affect the result very considerably. In this connection, we may mention that some time ago in our correspondence columns Mr. R. S. HALE, of the Edison Electric Illuminating Co., Boston, gave an average figure of between 2½ and 5 for residential lighting for an infinite number of consumers; whilst Mr. F. FERNIE estimated for private house lighting in this country a value for the diversity factor of something over 1·5.

The Local Government Board and Street Lighting.

THE recent Local Government Board inquiry at Grimsby found Mr. H. R. HOOPER, the L.G.B. Inspector, in a critical frame of mind. The question at issue was whether a loan of £2,000 should be granted for the purpose of lighting the side streets by means of metal filament lamps. The Public Lighting Committee are of opinion that a better light can be obtained electrically than by the existing gas lamps. Mr. HOOPER, however, seemed to think that this was by no means evident, and he criticised some of the existing lighting, more particularly the arc lamps (which, by the way, are of an old type and are being replaced out of revenue), although this method of lighting was by no means connected with the question at issue. Mr. HOOPER concluded by stating that the Committee would have to show that the new light would be an improvement and that they could give electric light quite as cheaply. There is much to be said in favour of a due regard to such questions as cost and efficiency on the part of the Board, but we fail to see why Mr. HOOPER should proceed further and question the efficiency of the metal filament lamp for street lighting. Apparently, he is of opinion that the 63-watt lamp does not give anything like 50 c.p., and, that if it does, its life must be only 200 or 300 hours. Mr. W. A. VIGNOLES, Borough Electrical Engineer, stated that this was by no means the case, and that lamps in actual use at Grimsby had shown a life of 1,900 hours. Certainly this is borne out by the experience

Digitized by Google

of other engineers, and we think that Mr. HOOPER might have made himself better acquainted with the position.

Rival Illuminants.

IN view of frequent statements that artificial illumination by gas is many times cheaper than where electricity is used, and of attempts to belittle the progress of electric lighting, it is interesting to notice that the gas industry does not view the present position with equanimity. Thus, at the meeting of the Welsbach Incandescent Gas Light Co. last week the Chairman referred to the "severity" of electric light competition, which had now made itself felt even in regard to the illumination of small houses. That the Company fully appreciate the future importance of electric lighting is shown by the Chairman's statement that the Board were convinced that they had adopted a right policy in entering the electrical business. Attention may also be called to the fact that whilst many electrical engineers are endeavouring to encourage the use of light units of greater candle-power, one of our contemporaries connected with the gas industry has been drawing attention to the frequent efforts now made to show gas consumers how they may effect considerable economies by the adoption of lower units of light where applicable. In this connection it is mentioned that burners may shortly be expected which will only consume between $\frac{1}{2}$ and $\frac{3}{4}$ cubic foot of gas per hour and give a light of about 17 candles. The advantages possessed by electric lighting in the way of easy control by switches has led to many attempts to introduce similar facilities with gas lighting. The apparent reluctance of the public to experiment with such contrivances, however, has doubtless led our contemporary to suggest that "a house after dusk always looks brighter, and gives the inmates a greater sense of comfort, by having a light in almost every room. With the small incandescent burner units this condition can be satisfied in an inexpensive way." We fail to see, however, how the inmates can see the house look brighter unless all the doors are thrown wide open, whilst the effect on the atmosphere of a gas jet in every room is not pleasant to contemplate. Moreover, most of us have an inherent desire to economise in these days of increasing financial burdens, and thus the switch is important, even with a more efficient light.

Power Plant on Piles.—According to the "Electrical Review and Western Electrician," the new station of the Atlantic City Electric Co., which is being built in a meadow near New York Avenue, offers considerable difficulty to the selection of a stable and permanent style of foundation. Owing to the extremely marshy character of the soil it was necessary to plan a piling system, and from the results of tests it is calculated that fifteen hundred and thirty piles will be necessary to support the station. The tops of these piles will be 6 in. below the level of low tide so that they will be constantly submerged. Upon them will be placed a solid mat or pad of concrete, upon which will rest the building and machinery foundations, some of which will be carried to 10 ft. above low tide.

1,200-volt Continuous-current Traction.—According to "Engineering News," fourteen 1,200-volt direct-current systems for railways are at present in operation. Two of these are in Italy and 12 are scattered about the United States. It is stated that over 66,000 H.P. of 1,200-volt motors had been built or ordered up to December 31, 1909.

Electric Traction in Chicago.—A recent issue of the "Electric Railway Journal" mentions that the Chicago Elevated Railway Commission is considering five plans to solve the problem of "through routes" for elevated trains in that city. Thirty-eight plans were submitted to the Commission, and five of these were selected for more careful study. Mr. B. J. Arnold, who is chairman of the Commission, feels that progress has been made in narrowing down the work. It is pointed out that each of the four elevated railway companies is operating under a separate ordinance granted by the city, and that the interrelation of the elevated lines is caused by the joint use of the "down-town" Union loop. The companies are doubtful whether they can afford to haul passengers for a greater distance than about 6 miles for 2½d., but there is apparently a desire on the part of everybody concerned to reach a solution of the question if possible.

Curious Interruption to Service at the Gary Steel Works. Several interruptions to the electric service have lately occurred at these works without apparent reason. As will be remembered, the works are to a large extent operated by electricity generated on the premises by a large gas-engine plant, although connection can be made to an outside supply in cases of emergency. In seeking to determine the cause of the trouble, one man, said to be the night foreman of the power plant, was particularly zealous. One evening this man was found unconscious at the entrance to the concrete tunnel in the basement of the power house. When revived, he declared that he had solved the mystery, and that his injury had been caused by an intruder whom he had found meddling with the electric plant. Investigation is said to have proved, however, that the injured man himself was the meddler. The trouble was caused by short-circuiting the 'bus bars by a piece of iron pipe, and the mischief maker is believed to have struck an iron beam in hurriedly emerging from the tunnel, fracturing his skull. No serious damage was done to the plant, although the trouble caused the Steel Company some delay and annoyance. No motive is ascribed for the deed, and the sanity of the man who perpetrated it, and who is now in the hospital, is questioned.

Possibilities of Electric Traction in Japan.—According to the "Electrical World," in the opinion of an observant traveller who visited Japan recently there is a large future in that country for electric railways in addition to the Government steam railway system. This opinion is confirmed by interviews with a number of Japanese who are well informed on the situation. For a number of years, interrupted only by the exigencies of war, the Japanese Government has been taking over the steam railways belonging to private corporations and has been building connecting links to complete the system. The Imperial Government railways now consist of 5,248 miles of road and there are only 445 miles of road in the country under private ownership. These lines are widely scattered and have been built to serve private interests, such as mining works, rather than public needs. Ten years ago the Government owned but 979 miles of the 3,172 miles then in operation. One reason for believing that future railways will be largely electrically driven is that Japan has many water-powers which are going to waste, and these powers could be used to operate electric railways for feeding the steam lines in districts which are not reached by the latter. These lines should be cheaply constructed, for, apart from the rails, material is plentiful and labour is cheap. Japan, for instance, is sending sleepers to both the United States and China. The Government now operates about 25 miles of trolley lines round Yokohama Bay, and is extending these lines. The tramcars use the same stations as the steam railways in many places and connections are made between the two systems of transportation. Another reason why electric railways are well suited to supply the needs of

Digitized by Google

Japan is that the chief function of the steam railways at the present time is the transportation of passengers. According to the last report of the Imperial Government railways, the receipts from passengers were £3,757,373 and from freight were £2,930,362. The passenger business more than doubled during the year. There is provision for three classes of passengers, and an analysis of the traffic shows that the third-class passengers were carried at the rate of a little more than 0·35d. per mile, and that the average fare paid by each passenger of this class was about 7½d.

London, Brighton & South Coast Railway Electrification. As we have already announced, nothing has been definitely decided concerning the further electrification of the suburban service of the Brighton Railway Co., but when the shareholders of the Company next meet it is probable that a definite scheme will be laid before them for the electrification of that section of the Company's suburban line which runs to the Crystal Palace. It is to be greatly regretted (on behalf of the Crystal Palace Co.) that this step could not have been taken by the Brighton Railway Co. at an earlier date. This, however, was not the fault of the railway company, as modern practice was not sufficiently advanced to admit of so important a step being taken earlier. We hope it will not now be too late to serve as an aid to the better financial position of the Crystal Palace.

Wireless Telegraphy on the Eiffel Tower.—At midnight of May 23rd a wireless message will be dispatched from the Observatory on the Eiffel Tower to vessels at sea. There is also a specially-designed clock on the Tower which, according to the "Matin," sends out at frequent intervals a different electric signal, and it is asserted by Capt. Guyon and M. Bouquet de la Grye that by this means the longitude of a distant locality can readily be calculated when local time is known. The object of the first-mentioned operation is that all chronometers at sea may be checked at noon, 8 p.m., and midnight. It will be remembered that the installation on the Eiffel Tower is already in regular communication with Dakar, Port Étienne and Rufsque on the Atlantic coast of N.W. Africa, as well as with the Canary Islands, and with Bizerta and Oran on the Mediterranean coast, and it is anticipated that the next group to come into the network will include Abecher and Loango and Brazzaville in the interior of Africa, and, later, that Port Étienne will be in direct touch with several South American countries.

Electric Locomotives on the Loetschberg Line.—According to "Le Genie Civil" the Bernese railway authorities have recently ordered some electric locomotives for operating this line. They will be of two different types of construction. The first type is carried on two bogies, the three axles of which are coupled together. Each of these bogies is operated by a 1,000 H.P. motor through cranks and gearing. Each motor is fed with current at a pressure of 420 volts, the line voltage being 15,000. The electrical equipment weighs 42 tons, and the locomotives complete weigh 86 tons, the axle pressure being 15 tons, except on the two end axles, where it is 13 tons. The tractive effort is 12·8 tons at a speed of 26 miles an hour. The second type of locomotive has a capacity of 1,600 H.P., and is made up of two identical units coupled together. Each of these units is fitted with motors which drive the axles through cranks, but without gearing. Each motor is fed from the secondary of a transformer, the output of each unit being 800 H.P. The electrical equipment weighs 50 tons and the locomotives complete weight 93 tons. These machines are designed for running at from 43 to 45 miles per hour.

Electrification of the Boston Railways.—According to the "Electrical World" public opinion in favour of electrification of the steam railways at Boston continues to exert pressure upon the legislature for early action requiring the adoption of electricity in the metropolitan district. A long statement was issued last week by Mr. W. C. Ewing, chairman of the Committee on transportation of the United Improvement Association, refuting some of the arguments of counsel at recent legislative hearings against electrification. It was pointed out that while the advantages of eliminating the smoke nuisance had been given considerable emphasis at hearings before the legislative committee on metropolitan affairs, the great transportation advantages of electrified service had repeatedly been emphasised before the legislature. Economy of operation derived from the running of short and frequent trains will benefit the public and the railroads. Short, frequent trains are exactly what the "suburbanite" needs. The flexibility of electrification will give more frequent service at reduced cost; the elimination of shunting will be most advantageous, and overcrowding will be diminished. With more frequent and cleanly service, population will be attracted to the suburban territory, as it is not under the present régime. The traffic of the railways will be greatly increased by the introduction of electric service. The Railroad Commission and the Joint Board of Metropolitan Improvements are strongly in favour of electrification, and it is contended that it is time for the legislature to take definite action requiring the railroads to make a positive move in the matter instead of postponing the introduction of a type of service desired by practically the entire population of eastern Massachusetts.

Static Strains in H.T. Circuits.—In a recent issue of the "Electric Journal" Mr. P. H. Thomas summarises the results of some experiments he has made on this subject. He states that when a "dead" transformer is connected to a live line a strain may be produced on the layers of the coil next to the terminal which may be as great as the line voltage. When a short line is charged suddenly from live 'bus bars there may be produced a momentary voltage which will be not more than double the normal. When a long line is charged, a strain similar to that in the short line is produced, doubling the potential first at the end of the line and afterwards along the whole length. This result assumes that the charging terminal of the line is abruptly raised to and maintained at full normal potential until the wave is fully formed, and also that the losses are zero. The fundamental principles governing the charging of a cable are the same as those of a transmission line. Opening an unloaded high-tension circuit may be nearly the equivalent of charging the circuit, since before the line is completely freed from the 'bus bars it is often momentarily recharged several times. When a branch of small electrostatic capacity is supplied with energy from a main line, the rise of potential at the farther end may be twice as great as at the end of the main line. In addition to switching, other causes of static strains are earthing, short-circuiting, lightning, &c., when these cause abrupt changes of potential. A rise of potential due to resonance is always possible, but genererally improbable. It requires that there be an oscillating circuit and an exciting cause which must be of very nearly the same frequency as the natural period of the oscillating circuit. When an alternating E.M.F. of high frequency is applied to a long line the danger that resonance will occur is usually greatest, as it may be produced by a large number of frequencies. High-voltage transformers should be so designed as to possess a good and constant factor of safety, both in the outlet terminals and between those turns of the winding which are next to these line terminals. This can usually be accomplished by providing extra insulation on the end portions of the windings, and by eliminating all voltage taps from these parts, confining them to the inner turns of the windings.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. A. Fraenckel and Mr. B. J. M. Lane contribute an article on "Short-Circuit Losses in Alternating-Current Commutator Motors."

We give the first instalment of an article describing the new generating station of the Westminster Electric Supply Corpn.

We also give an account of the electrical equipment at Smith's Docks, Middlesbrough.

We conclude our abstract of the Paper on "Commutation Phenomena," read by Mr. G. W. Worrall before the Birmingham local section of the Institution of Electrical Engineers.

Digitized by Google

Fulham (London) Council have adopted a scheme of free wiring of consumers' premises and also for letting metal filament lamps on hire for outside shop lighting.

An inquiry has been held into the application of Wimbledon Corporation for permission to borrow £5,800 for electricity supply extensions.

The report on the past year's working of Birmingham electricity supply undertaking has been issued, and shows that substantial progress has been made. Considerable extensions of the generating plant and mains are projected.

Companies' Meetings, &c.—The report of the Anglo-Argentine Tramways states that a concession has been obtained by the Company for the construction of subway electric tramways of an aggregate length of about 10 miles. The Company's concession has been fixed at 80 years, and it is proposed to create new capital to provide money for the new lines, extensions of the system, &c.

The report of the Allgemeine Elektricitäts Gesellschaft (Berlin) states that business is satisfactory, but prices have been affected by keen competition. Several of the departments show an increased output compared with the corresponding period last year.

INSTITUTIONS AND SOCIETIES.

Glasgow Section of the Institution of Electrical Engineers.—At a meeting of this Section on May 10th Mr. E. G. Tidd, the chairman, moved that a loyal address and vote of condolence be sent through the parent Institution to His Majesty King George V. The local committee as nominated were elected. It was intimated that it had been agreed that the local Section should unite with the Iron and Steel Institute for a joint excursion on the Clyde in the specially chartered steamer "Duchess of Hamilton" on June 9th.

Newcastle Section of the Institution of Electrical Engineers.—The following are the nominations proposed by the committee for the session 1910-11: *Chairman*, Mr. C. Faraday Proctor; *Vice-Chairman*, Mr. C. S. Vesey Brown; *Past Chairmen*, Messrs. J. Pigg, Mr. A. L. E. Drummond and Prof. H. Stroud; *Committee*, Messrs. J. A. Anderson, L. E. Buckell, E. Fawssett, H. F. Fisher, H. Henderson, J. H. Holmes, F. O. Hunt, W. D. Hunter, G. Ralph, H. L. Riseley, J. M. Robb, R. Rutherford, G. Stoney, C. Vernier, W. W. Wood and Prof. W. M. Thornton; *Hon. Secretary*, Mr. H. W. Clothier; *Hon. Treasurer*, Mr. W. A. Clatworthy.

Students' Section of the Institution of Electrical Engineers.—The annual report of this Section states that during the past session there have been 10 general meetings and the annual general meeting held in the Library of the Institution, in addition to those held by the local sections; the average attendance at these meetings was 25, the highest recorded being 35 on February 2nd. The opening address was delivered by Mr. J. H. Rider on November 17th and was entitled "The Importance of Attention to Details." Ten Papers, ranging over numerous subjects, were read and discussed. In pursuance of the idea adopted last session no visits have been arranged this year, but the committee would welcome any suggestions, especially to visit places which perhaps could not be seen except under the ægis of the Institution. The committee have adopted this course in view of the fact that the need for such visits is now amply supplied by the college engineering societies. Thirty-eight students took part in the summer tour to Germany, which, due to the efforts of Mr. E. W. Moss, was a pronounced success. The committee desires to place on record its appreciation of Mr. Moss's organisation of the tour. A tour has been arranged to take place from July 25 to July 30, 1910, to visit works in and around Birmingham. The sixth annual dinner took place at the Trocadero Restaurant on Wednesday, January 26, 1910. The dinner was very successful, but the number present was not so large as was hoped, and the Committee feel that this function does not receive the support it deserves from the Students' Section as a whole.

Institute of Metals.—As already announced, the annual May lecture of this Institute will this year be delivered by Prof. Gowland, F.R.S., who will take as his subject "The Art of Working Metals in Japan." The lecture will be given on Tuesday, May 24th, at 8:30 p.m., at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. Prof. Gowland's discourse will be illustrated by numerous diagrams and lantern slides. It will be of a topical character, in that it will deal with metallurgy in Japan, a country in which great interest is now being displayed as a result of the recently opened Japan-British Exhibition. In view of the special interest of the subject of the lecture, the Council of the Institute of Metals have decided not to confine admission entirely to members of the Institute. Tickets admitting visitors may therefore be had gratuitously on application to the secretary of the Institute, Mr. G. Shaw Scott, Caxton House, Westminster, S.W., to whom applications for tickets should be made not later than Saturday next.

International Congress of Radiology and Electricity.—We understand that a number of Papers have been promised for this congress, which, as we have already announced, will be held at Brussels on September 15th, 16th, and 17th. The range of subjects covered is very large. We are requested to state that communications relating to the physical sections should be addressed to Prof. Rutherford or Mr. W. Makower, at the Physical Laboratory, University of Manchester, and communications relating to the biological section to Dr. W. Deane Butcher, "Holyrood," Ealing, London, W. Intending members should, however, communicate directly with the general secretary, Dr. J. Daniel, 1, Rue de la Prévôté, Brussels.

Verband Deutscher Elektrotechniker.—The eighteenth annual meeting of this association will be held at Brunswick on May 25th, 26th, 27th and 28th. An extensive programme of lectures and Papers has been arranged, among them being the following: "On Art in Technology," by Prof. P. Behrens; "On the Latest Results obtained with Electric Cables on Extra-high Voltages," by Dr. L. Lichtenstein; "Indirect Lighting by High-Candle Power Tungsten Lamps," by Dr. B. Monasch; "The Compound Commutator Single-Phase Motor operating as Motor and Generator," by Mr. R. van Cauwenberghe; and "New Automatic Switchgear and Speed Indicators," by Dr. E. Wagmüller, as well as a discussion on the subject of "Electricity on the Land." Excursions and visits will be made to places of interest in the neighbourhood.

Society of Engineers.—We have been requested by the Secretary to remind our readers that the latest date on which essays in competition for the Status Prize can be received is Tuesday, May 31, 1910.

Railway Signal and Telegraph Engineering Institute.—A meeting of the members of the above Society was held at the St. Marylebone Church Institute on Wednesday, April 27th, at which Mr. E. Hollman, of the Metropolitan Railway, read a Paper on the "Spagnolletti System of Interlocking," as installed on a portion of that railway. The Paper was illustrated by a number of sketches, and an installation of the actual instruments as used, these being kindly lent by the engineer. After the reading of the Paper an interesting discussion took place, and a practical demonstration of the working as between two signal cabins was given, at which Mr. W. J. Buck assisted.

ARRANGEMENTS FOR THE WEEK.

MONDAY, May 23rd.

The National Electrical Manufacturers' Association.

8 p.m. Meeting at Caxton Hall, Westminster. Discussion on "The Effect of Free Trade or Protection upon the Electrical Industry," to be opened by Mr. Hugo Hirst (from the Protection point of view) and Mr. J. E. Kingsbury (from the Free Trade point of view).

THURSDAY, May 26th.

Royal Institution.

3 p.m. Meeting at Albemarle-street, Piccadilly. Lecture on "The Constitution and Internal Structure of Alloys," by Mr. W. Rosenhain (Lecture I.)

Institution of Electrical Engineers.

8 p.m. Annual General Meeting at the Royal Society of Arts, John-street, Adelphi.

FRIDAY, May 27th.

Physical Society of London.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: (1) "On an Oscillation Detector actuated solely by Temperature Variation of Resistance," by Dr. W. H. Eccles. (2) "Exhibition of a Resonance Transformer," by Mr. A. Eagle. (3) "The Limitations of the Weston Cell as a Standard of Electromotive Force," by Dr. S. W. J. Smith.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, May 23rd.—"A" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 9:30 p.m.

Tuesday, May 24th, "B" Company.—Company Drill, 7 to 9:30 p.m.

Wednesday, May 25th.—Gymnasium, 6 to 9:30 p.m.

Thursday, May 26th, "C" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

Friday, May 27th, "D" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7:15 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

Saturday, May 28th.—Musketry at Runemede.

NEW GENERATING STATION OF THE WESTMINSTER ELECTRIC SUPPLY CORPORATION.

Of the many metropolitan electricity supply companies, the Westminster Electric Supply Corporation, if not the oldest, must be numbered among those that started in the earliest days of electric lighting. The oldest is the London Electric Supply Corporation, which has completed 24 years of its career—many of them exceedingly eventful. The Kensington Company comes next, having supplied for 22 years, and two other companies have been in operation for 20 years, while over 19 years must go to the credit of the Westminster Corporation. It was so far back as 1889 that the Company obtained a provisional order, and in 1890 operations were commenced, a description of the original scheme appearing in THE ELECTRICIAN of October 31, 1890. Prof. (now Sir) Alex. B. W. Kennedy was appointed engineer of the undertaking in January of that year, and has since that date been continuously connected with the undertaking, the most recent generating station of the Company being designed by him. The reason for laying down this station and the arbitration in connection therewith are probably still fresh in the minds of our readers, but it may be as well here briefly to summarise the proceedings.

By the London County Council Act, 1900, the Council were empowered to obtain possession of the site of the Millbank-street station of the Westminster Electric Supply Corporation in connection with proposed improvements, including the construction of an embankment. Although the Council have not, up to the present, made much progress with this scheme, the supply company naturally felt the uncertainty of their tenure of the Millbank-street site, and were anxious to obtain the new station and site, which, by the terms of the Act, the London County Council had to provide. After lengthy negotiations, a site in Horseferry-road was offered to the Company. This site, although much larger than the Millbank-street site, had the disadvantages, compared with the latter, that it was no longer possible to obtain water-borne coal, or to dispose of ashes except by means of carting, whilst water for condensing purposes was not so easily obtainable as in the case of the Millbank-street station, which was close to the river.

These considerations were discussed in the arbitration which commenced in October, 1908, and which was reported in THE ELECTRICIAN of October 30, 1908, and subsequent issues. As the result of this arbitration the Council agreed to pay to the Westminster Electric Supply Corporation a sum representing the difference between the cost of coal delivered at Horseferry-road and of coal brought by barges to the Millbank-street site. This increase in cost was stated at the time of the arbitration to amount to no less than 2s. 6½d. per ton. It will be seen that as this agreement remains in force until 1931, when the electricity undertaking becomes purchasable by the Council, a very large sum is due to the Westminster Electric Supply Corporation on this account.

The Council also arranged to construct a subway and to lay four 20 in. pipes from the new generating station to the river, so that water for condensing purposes would be available from that source. The arrangements in connection with this supply of water are probably the most interesting feature of the new station.

An idea of the distance over which the condensing water has to be brought can be obtained from Fig. 1, which shows the general arrangement of the pipes. It may be mentioned that no grids are fixed at the intakes on the bed of the river, all strainers being situated in the power station. The four pipes are of slightly different lengths, so that the hot discharge from any pipe is not liable to enter other pipes through which cold water is flowing.

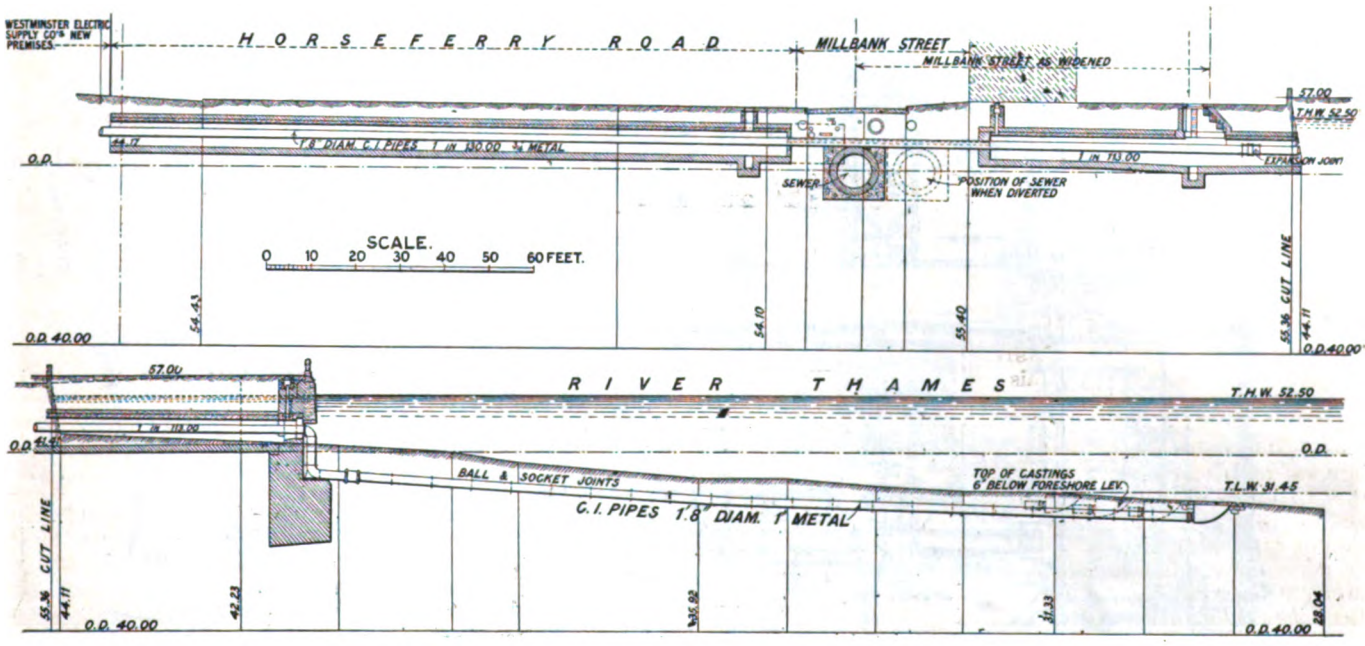

FIG. 1.—LONGITUDINAL SECTION OF SUBWAY AND WATERPIPES FROM HORSEFERRY-ROAD STATION TO THE RIVER.

Grids, comprising bars spaced about ⅞ in. apart, are fixed at the station on each of the four pipes and a very ingenious system has been adopted for minimising trouble due to choking of the grids and pipes. All the discharge from the condensers is passed through one pipe, whilst the other three pipes can, if necessary, be used for the intake. This results in the discharge pipe and grid being well scoured out, due to the high velocity of the water. When the pressure gauges show that any intake pipe is becoming choked, such pipe is used for the discharge from the condensers, and the pipe previously used for the discharge, and which has become cleared from deposit, is utilised for the intake. By changing over in this way it is possible to keep the pipes in a satisfactory condition, and to prevent a great deal of the trouble likely to arise where river water containing a lot of foreign matter is used for condensing purposes.

The water is drawn from the river by three electrically-driven Rees Roturbo pumps, and after passing through the above-mentioned grids and through these pumps, as can be seen from Fig. 4, the water flows through a Bailey and Jackson.

Digitized by Google

rotary strainer, of which two are installed. The principle of this useful apparatus is now well known, owing to the attention which was called to it in connection with Mr. Rider's I.E.E. Paper on "The Electrical System of the London County Council Tramways." It will be remembered that these strainers, which are due to Messrs. Bailey and Jackson, of the City of London Electric Lighting Co., have proved very satisfactory at the Greenwich station of the Council. The unstrained river water passes through a slowly revolving grid on its way to the condensers, whilst the discharge flows through the grid in the opposite direction, thus washing away any deposit clinging to the strainer surface. The grid is rotated at a speed of about one revolution in two minutes. Each strainer is capable of dealing with 325,000 gallons of water per hour normally, and not less than about 500,000 gallons per hour in an emergency. It consists of a cast-iron casing in four parts, the casing being mounted upon a substantial cast-iron base, and provided with 18 in. inlets and outlets. Internally it is fitted with two rubbing strips, faced together back and front. An inspection cover is provided on the outside circumference of the top casing, while side inspection is provided for by four inspection blank covers. The cast-iron rotor, about 60 in. in diameter, is fitted with specially constructed brass grids, and is mounted upon a main shaft of 5 in. diameter, with gunmetal and leather packing rings, arranged to prevent the bye-passing of water as far as possible and also to allow of easy access for overhauling and repairs. A 1 in. water service for maintaining the water seal is provided, and the quantity of sealing water for each strainer amounts to about 400 gallons per hour.

Since at low tide the pumps are from 8 ft. to 10 ft. above the level of the river, it is evident that care must be taken to obviate trouble due to air accumulating at the highest points in the pipes so causing the pumps to lose their suction. As a precaution, therefore, a vacuum pump has been installed in the station and is connected to the higher points in the pipes; in this way air pockets are prevented.

Attention has already been called to the disadvantage of the new site in Horseferry-road as regards facilities for obtaining coal and the removal of ashes. Both these operations have to be carried out by means of carts. The general arrangement can be understood from Fig. 2, which shows diagrammatically the coal and ash-handling plant. Coal is tipped from carts at the roadway, indicated in Fig. 2, into a hopper on the basement floor. From this hopper a continuous conveyor, of the swinging bucket type, and supplied by Messrs. Spencer & Co., of Melksham, Wilts., raises the coal and conveys it into bunkers over the boiler house, measuring boxes and shoots being fixed as shown for each boiler. The conveyor is capable of dealing with about 25 tons of coal per hour, and is driven by a totally enclosed motor. All parts of the conveyor outside the building are covered in and protected by a framework of steel plates.

The ash transporter was specified to lift, at a rate of about 50 ft. per minute, a skip containing 40 cubic ft. of wet ashes from the basement outside the boiler house to the ash bunker overhead, from whence they are discharged through shoots to carts.

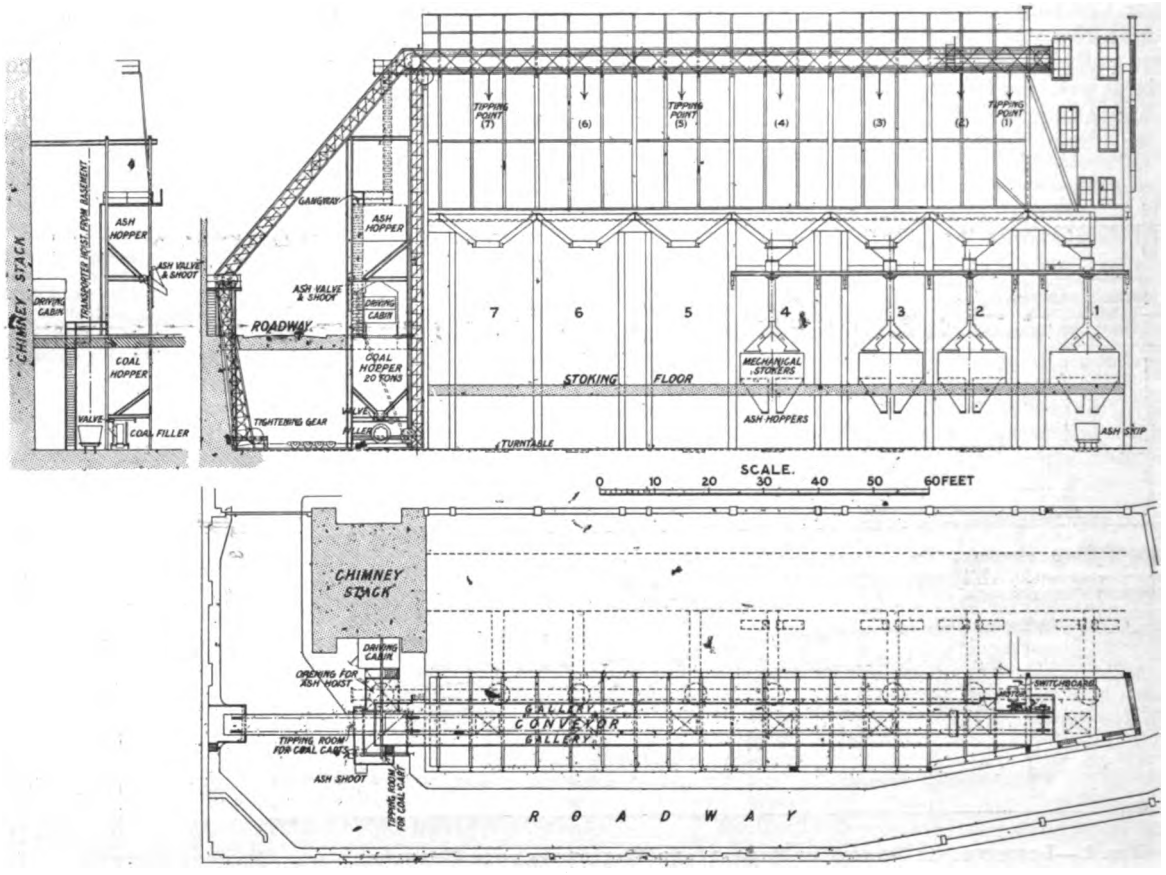

FIG. 2.—COAL AND ASH HANDLING PLANT.

The transporter is driven by a series-wound direct-current enclosed motor. Each ash skip stands on a trolley which runs on rails on the boiler house basement floor.

Before considering in detail the plant installed in the new station, it is interesting to note that by their Act the Council had to provide plant in the Horseferry-road station of equal capacity to that possessed by the supply company in their Millbank-street station. As a matter of fact, however, the new plant is of slightly greater capacity, the excess being paid for by the Company. The Millbank-street station has now been shut down, and was handed over to the Council on the first day of this month. The result is that the Westminster Electric Supply Corporation are now in possession of a station designed on modern lines, and considerable economies are expected to be shown in the costs of generation. The buildings have been constructed to meet all requirements until the undertaking becomes purchasable by the Council in 1931. As in the case of the Millbank-street station, a low-tension continuous-current supply only is given, but several motor-generators are installed,

Digitized by Google

in which high-tension three-phase current supplied from the Grove-road station of the Central Electric Supply Co. is transformed to continuous current, these machines operating in parallel with the main generators.

Boilers.—Four Babcock & Wilcox boilers have been installed, each being fitted with superheater and operated in connection with an economiser. Each boiler, fitted as above, is capable of evaporating normally 20,000 lb. of water per hour, from a temperature of 75°F., into steam at a pressure of 200 lb. per square in. with 150°F. superheat; whilst when necessary each unit is capable of evaporating 25,000 lb. of water per hour.

The superheaters are of the usual Babcock type, consisting of solid drawn mild steel tubes 1½ in. external diameter, bent to shape and expanded at the ends, with wrought steel boxes.

The mechanical chain-grate stokers are of Messrs. Babcock & Wilcox latest pattern. In this, the movement of the grate is continuous, differing in this respect from earlier patterns, where a ratchet and pawl drive was adopted. The links are also closer together. This fact, together with their steady movement, allows a smaller class of coal to be burnt. The speed of the grate bars is variable to suit different classes of coal and conditions of firing, whilst the hopper is so arranged that the fuel is spread over the whole width of the grate, the thickness of the fire being regulated by a vertical movement of the fire door.

The shafting for driving the stokers extends for the whole length of the boiler house, and an electric motor is installed at each end, a clutch disconnecting either motor as required.

Each economiser consists of 160 solid drawn mild steel tubes, $3_{1}\frac{3}{8}$ in. outside diameter.

Water for the boilers is supplied by two Weir feed pumps and an electrically driven centrifugal pump by Messrs. W. H. Allen & Son, each being capable of delivering 60,000 lb. of water per hour against a boiler pressure of 210 lb. per square inch. The electrically driven pump is found to be more economical, but, on the other hand, the steam pumps will generally be employed, since the exhaust steam from these pumps is taken through a feed water heater, so that the feed water may be raised in temperature before it enters the economisers.

A Lassen and Hjort water-treating and filtering plant has been installed for softening the make-up water for the boilers, and among other accessory plant may be mentioned two Lea water recorders, one measuring the hot well discharge and the other the make-up water, and a CO_2 recorder. The whole of the above plant, together with electrically driven centrifugal pumps for the hot well, &c., and all the pipe work has been carried out by Messrs. Babcock & Wilcox.

(To be continued.)

ELECTRIFICATION OF INSULATING MATERIALS.*

BY W. JAMIESON, B.SC.

The difficulty of carrying out experiments in electrostatics in this climate is well known, and as the author has had occasion for some years to show experiments of this kind to large classes of students, frequent failures led him to investigate the best kind of materials to use for producing electrification in a humid atmosphere. Of all the substances tried, by far the best was rolled celluloid sheet, particularly if the surface were well burnished. This, under the worst possible atmospheric conditions, electrifies with ease, and a gentle rub with the fingers suffices to raise the substance to a very high potential indeed. While this has to some extent been already known, though not made use of, in the manufacture of electrostatic apparatus, a further curious effect was discovered during the investigation; if two pieces of this celluloid sheet be drawn smartly between the finger and thumb, not only are the outsides electrified but the inside surfaces as well, one being positively the other negatively electrified. While seeking for an explanation of the phenomenon I found that on every occasion on which I tried the experiment the strip in contact with the thumb was +, but on asking others to try, no consistent results could be obtained; sometimes one strip was positively electrified, and on the next attempt negatively electrified.

Mr. M. MacCallum Fairgrieve, of Edinburgh Academy, having tried the experiment, found that the kind of electrification seemed to depend on whether the pieces were bent to one side or the other when drawn through the fingers, and this seems to be the true explanation. When the two strips are drawn through the fingers they are not only compressed but bent to one side or the other. Of the two inner surfaces in contact one is concave the other convex, that is, the particles of the one surface are in compression and those of the other in tension. The molecular difference due to this tension and compression combined with the direct pressure evidently produces the electrification.

Of the surfaces in contact the one in compression is, for celluloid and the other substances mentioned below, always negatively electrified, and the one in tension is always positively electrified. The amount of electrification is remarkable, in view of the minute differences one would expect to find in the two surfaces. In the dark a flash may be seen when the surfaces are separated, and if the experiment be repeated several times, a distinct odour of ozone is observed. Having found celluloid to possess this property, I proceeded to examine other substances, and got similar effects under suitable conditions with paper, shellac, substances impregnated or varnished with shellac, vulcanite and mica. Unless at suitable temperatures, and conditions of dryness, the effect with the materials mentioned is not so great as with celluloid. The fact that combined pressure and bending produced under suitable conditions electrification of insulating materials led naturally to the investigation of the electrification of layers of these materials as used in electrical machinery. Utilising celluloid as the most convenient substance it was found that if a layer of strips were subjected to combined pressure and bending, all the strips were electrified as explained above. It might be thought that since the quantities of electricity produced at the inner surfaces are equal in amount, and opposite in sign, no outward sign of the electrification should be apparent until the layers are separated. In practice this is not so, for immediately the bending and compressive forces are removed, the relative positions of the surfaces are altered; irregular leakage effects take place more at one place than another, and the result is that one electrification usually predominates, though the amount of this differential charge may be small.

In many electrical machines there are layers of insulating materials subjected to alternating stresses of pressure and bending combined; for example, in transformers due to the alternating field setting up vibrations, and in generators due to want of balance and change of flux. Is it possible that these layers could become statically charged in the way mentioned? To test this a layer of strips of celluloid was carefully discelectrified, and mounted, bent and compressed, on the base of a small motor running at 3,000 revs. per min. The spindle carried an eccentric load, thus vibrating the layers. After a time the layers showed electrification as a whole, while the separate strips were strongly electrified. At the same time a number of strips were fixed to the edge of a wooden disc (keyed on to the shaft of the motor) and loaded. This disc was eccentrically mounted. On rotating the motor at a rapid rate the layers became electrified as before. These experiments suggest the possibility of static charges being produced in electrical machines simply by vibration and rotation; it is possible, therefore, that cases of insulation breakdown may occur through these causes alone.

Besides the application to transformers and generators a further practical illustration of the phenomenon described is to be seen in printing machines. The author considers that much of the electrification of the paper produced in these machines is due to the combined bending and pressure exerted on the paper by rollers. It is probably for this reason that sometimes the sheets are + and sometimes — off the same roll. The author has constructed an electrical machine in which bands of celluloid running over pulleys produce + and — charges in this way. While the results given above are anything but complete and by no means conclusive, the author considers the subject worthy of further investigation. Though the differential charges mentioned are small they are cumulative and may become large in a long run. This would seem to indicate that more care should be taken to consolidate insulating material used in layers, and to prevent it coming adrift, and so setting up the kind of electrification mentioned.

DISCUSSION.

Mr. W. W. LACKIE (Glasgow), referring to the little sparks to be seen between the commutator bars, asked if such were due to the static charge referred to in the Paper.

Mr. CAMPBELL MCMILLAN thought that possibly the phenomena referred to in the note accounted for the static charges off belting. In the dryer atmosphere of New York he had seen a discharge across 14 in. to 18 in. Regarding the layers of insulation in the windings of machines, from a mechanical point of view any loose play was usually guarded against, more so at the end windings. In some large turbo sets which had broken down he found that there had been a material movement of the winding, due, no doubt, to the heavy torsional effects rubbing through the insulation.

Mr. W. MCWHIRTER had had much experience with faults, many of them inexplicable, but in view of the phenomena explained by Mr. Jamieson, there was no doubt that electrostatic action was the reason. Further, he found there was a greater tendency for this type of breakdown to develop on machinery with overhead lines, as the sudden release of the electrification in these lines during a thunderstorm, though there might not even be a lightning discharge, tended to puncture the insulation. As to the author's electrification of paper theory, he (Mr. McWhirter) over 25 years ago had been called in to try and get this trouble eliminated at a certain paper mill. His arrangement consisted of two rows of earth-connected discharging cones touching the paper both on the top and bottom sides, but he found that even that was not sufficient. Probably the scintillating sparking at the commutator bars referred to by Mr. Lackie was due to the fact that micanite, not mica, had been used as insulation between the bars. He thought there was also another cause—namely, the varnish in the insulation might have picked up small particles of carbon dust—a frequent source of trouble. Still there might be something in Mr. Jamieson's theory, as he only found the sparking referred to where micanite was used. As to static discharge from belting, he always found that the worst offenders in this respect were badly trimmed belts—*i.e.*, belts having a lot of slip, &c.—where the frictional theory of static electricity would account for the spark.

Mr. SUTCLIFFE stated that he had seen in many cases of armature breakdowns there were decided punctures, indicating that there was something in Mr. Jamieson's theory.

Mr. J. A. ROBERTSON (Greenock) gave an instance of a machine which had broken down in the equalising coils at the ends of slots. The insulation was presspahn paper. There was no evidence of the breakdown being due to rubbing of conductor against paper, but there were decided indications of puncture holes. He found that some of the best kept belt drives showed strong electrification, especially if the belt was of a laminated type.

Mr. JAMIESON, in reply, thought that the sparking between the bars would be due to the phenomena explained. In his experiments, he might say, he had made special precaution to prevent relative motion between the different layers of material. In regard to belts, from experiments he had made, he found that if two or more layers of celluloid or paper were made to pass over an even number of pulleys, say, 8 or 10, as shown in the diagram herewith, there was no sign of electrification, but if the laminated strip was made to pass over one or more (an odd number) of pulleys there was decided electrification.

* A Paper read before the Glasgow local section of the Institution of Electrical Engineers (slightly abbreviated).

TELEPHONE CIRCUITS.*

BY PROF. J. PERRY, F.R.S.

Summary.—The author gives an easy method of calculation for the spacing of Pupin coils. This method gives a result practically correct, and can be used in the case of any network or other combination of resistances, inductances and capacities.

About a year ago Mr. Sidney Brown told me that he wished to place contrivances at equal distances in telegraphic or telephonic circuits and that it was necessary to make calculations, beforehand, because in a telephone line, say, of 300 miles or more with similar contrivances inserted every 1 or 2 miles, it was practically impossible to proceed by any kind of experimental adjustment. He spoke of various kinds of contrivance involving combinations of condensers and inductance coils and transformers and even rotary motors and generators; some in series with the line and others as shunts to earth. Exact investigation of what occurs in telephonic and telegraphic signalling in general is quite impossible. Transmitting and receiving instruments are various in their complexity: signals give rise to all sorts of functions of time and space; cables are not uniform in character, and when they are loaded with inductances, capacities, &c., the expressions employed in exact mathematical analysis are too complex for even the greatest mathematicians to deal with. Ordinary people like myself ought to keep on the lower levels and not talk about "waves" in such problems. The fundamental equation for v or c in an ordinary cable is exactly the same as that for the conduction of heat through a solid bounded by parallel plane faces; in the heat problem nobody dreams of talking about waves. It is easy to convert the differential equations into wave equations, and in the hands of exceptionally clever men the physical ideas involved become important. Even when Mr. Brown's problem is taken up in a mere mathematical way it is troublesome, and I can offer no exact solutions. I have, however, found a simple method of making the kind of calculation required, correct enough for all practical purposes and the method can be applied by non-mathematical persons. I mean that the necessary calculations may be made by any person who understands formulæ sufficiently well to be able to apply arithmetic to them. The idea came to me at St. Louis when I was listening to a Paper by Prof. Kennelly, but I then had no interest in pursuing the subject. Prof. Kennelly has published many illustrations of great value of the use of *cosh* and *sinh* functions; he gets no more credit now than Columbus did after he showed how to make the egg stand upright.

Let me say that much of the arithmetic consists in converting such an expression as $\alpha+\beta i$, where i means $\sqrt{-1}$, to the shape $r(\cos\theta+i\sin\theta)$, which is conveniently written $r(\theta)$. I need hardly say that if this is raised to the nth power the result is $r^n(n\theta)$ where n may be negative or fractional. Also when $r(\theta)$ operates upon such a function of the time as $a\sin qt$ it converts it into $ar\sin(qt+\theta)$. Cosh $r(\theta)$ and sinh $r(\theta)$ will be found tabulated (for $\theta=45^\circ$) by Prof. Kennelly. Unfortunately for our purposes we use only small values of r for which Prof. Kennelly's tables have only a few entries. But calculation is easy enough. Write $r(\theta)$ in the shape $\alpha+\beta i$. Then

$$\cosh r(\theta)=\cosh\alpha\,.\,\cos\beta+i\sinh\alpha\,.\,\sin\beta$$

and

$$\sinh r(\theta)=\sinh\alpha\,.\,\cos\beta+i\cosh\alpha\,.\,\sin\beta,$$

so that the calculation is easy for any values of α and β.

I will first make a few statements, the foundation of my reasoning.

1. It is well known that any looped line or cable containing a receiving instrument at the end of the loop has its equivalent in a cable whose far end goes to earth through the receiving instrument, the outer coating of the cable being everywhere to earth or of zero potential. The mathematical proof of this is very easy and I shall not give it, although I do not know that it has been published.

2. In all difficult problems cables are so long that for all practical purposes we may suppose them to be infinitely long. Thus it is well known to practical people that when lines of 30, 40, &c., miles of the same cable are experimented upon, the rate of diminution of current per mile is the same except for regions near the ends, and these end effects are much the same for all lengths of line except in short lines.

3. In any long, uniform cable at equidistant points, A, B, C, &c., when a simple periodic current is flowing, its value at these points being, C_A, C_B, C_C, &c., the ratio of C_A to C_B is the same as that of C_B to C_C, &c. This is true except near the ends.

4. In a long cable with perfectly similar contrivances, A_1A_2, B_1B_2, C_1C_2, &c., at equidistant places A, B, C, &c.; when a simple periodic current is flowing, its value at corresponding points being A_1, A_2; B_1, B_2; C_1, C_2, &c., the ratio of A_1 to B_1 is the same as that of B_1 to C_1, &c., and these are also the same as the ratio of A_2 to B_2, B_2 to C_2, &c. We may say the same about the voltages at corresponding points. It is seen that I assume an infinite line, but even in the case of an infinite line my assumption is that there is *some* diminution in the amplitude of the current from A_1 to B_1. If the circuit behaved like a mere ohmic resistance the current would be the same everywhere but the voltage would not.

5. Neither telephone nor telegraph signalling can be studied correctly through the behaviour of periodic currents, but it has been found in practice that in telephony, if we assume that all currents are periodic functions of the time, the frequencies being not much less than 600 nor much greater than 1,000 per second, the most important being 800, good transmission of such currents is found to mean good transmission of speech.

6. It is quite a usual thing to find that experimenters are using transmitting and receiving devices which are not the best for a particular cable. For a receiving instrument, for example, there is a best resistance and inductance (or combination of inductance, capacity, back E.M.F., &c.). In every case yet studied by me (but I can imagine others) the most suitable receiver causes the current and voltage near that end of the line to be different from what they would be if the line were infinitely long. Thus, for example, with simply periodic currents in the standard cable it will be found that at any place far from the ends, voltage divided by current is of the form $r(-45^\circ)$ or $\alpha-\alpha i$. If the telephone or other receiving instrument has a resistance R and an inductance L, each of which is proportional to the square of the number of turns of wire upon it, and if the effect on the instrument (such as the deflection of a coil, &c.) is proportional to the current turns received, this effect is a maximum if $R=\alpha$ and if $L=\alpha/q$, where q is 2π times the frequency. It is easy to show that if we wished the receiving instrument to produce the same effect as an infinite prolongation of the cable, it ought to have a resistance R and a negative inductance $L=-\alpha/q$, which is a capacity $1/\alpha q$. It is then not merely when unsuitable instruments are used, but also when the most suitable instruments are used that we have end effects.

7. A line with equidistant similar contrivances, when they are not too far apart, may be replaced (mathematically) by a line whose properties (as to resistance, inductance, capacity, leakance, &c.) are continuous, for many purposes of calculation.

The simplest case of uniform distribution of properties in an infinite line was studied in my Paper read before the Physical Society in 1893. Let v and c be the voltage and current at any place whose distance from the sending end is x; let $v_0\sin qt$ be the voltage when x is 0. If r, l, s and k are the resistance, inductance, leakance and capacity per unit length, we have

$$v=v_0e^{-hx}\sin(qt-gx), \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where

$$\sqrt{\frac{kqr}{2}}\sqrt{\sqrt{\left(1+\frac{q^2l^2}{r^2}\right)\left(1+\frac{s^2}{k^2q^2}\right)}\mp\left(\frac{ql}{r}-\frac{s}{qk}\right)} \quad (2)$$

is the value of h if the minus sign be taken and the value of g if the plus sign be taken. The following formula for the current c is useful—

$$c=\sqrt{\frac{h^2+g^2}{r^2+q^2l^2}}v_0e^{-hx}\sin\left(qt-gx+\tan^{-1}\frac{g}{h}-\tan^{-1}\frac{lq}{r}\right). \quad (3)$$

I showed in tables how good signalling was affected by changes in the values of the constants and specially by alterations in l and s. There was nothing very new in my Paper, but it enabled the non-mathematical man to understand some of the discoveries of Mr. Heaviside. At that time I saw no easy way of calculating how the introduction of detached equidistant contrivances caused discrepance from the idea of continuously distributed properties.

In much that follows, lq will be so large compared with r that, taking $s=0$, we have $h=\frac{r}{2}\sqrt{\frac{k}{l}}$; $g=q\sqrt{kl}$. If s is small but not negligible, g is as before, but

$$h=\frac{1}{2}\left(r+\frac{sl}{k}\right)\sqrt{\frac{k}{l}}.$$

As for other uniform distribution of properties, it is only necessary here to speak of those which may immediately be put in the above shape. For example, besides having merely r and l in series in the line, we may have something of the nature (mathematically) of k_1 farads per mile, so that instead of $r+lqi$ we have $r+lqi+1/k_1q_1$ or $r+qi(l-1k_1q^2)$. This is as if we had merely the resistance r and an inductance $l'=l-1/k_1q^2$.

Again, instead of the leakance s which is the reciprocal of a resistance R, let us have also something of the nature of an induc-

* Paper read before the Physical Society. A short account of the discussion which followed the reading of this Paper appeared in our issue of March 11th, p. 902.

Digitized by Google

tance L, say, and assume R to be small relatively to Lq. Then instead of s we have

$$\frac{1}{R+Lqi}=\frac{R}{L^2q^2}-\frac{i}{Lq}.$$

Thus the common expression $s+kq$ becomes $\frac{R}{L^2q^2}+qi\left(k-\frac{1}{Lq^2}\right)$.

For preliminary calculations it is generally sufficiently correct to assume R/L^2q^2 to be zero.

We may now consider that the telephone line has, per mile, a resistance r, an inductance $l'=l-1/kq^2$, a leakance $s=0$, and a capacity $k'=k-1/Lq^2$. It will be found desirable in almost all cases to have l' so large that we may take $h=r/2\sqrt{k'/l'}$ and $g=q\sqrt{k'l'}$. Assuming these conditions to exist we have, very nearly,

$$c=\sqrt{\frac{k'}{l'}}v_0\epsilon^{-\frac{1}{2}rx\sqrt{k'/l'}}\sin(qt-qx\sqrt{k'l'}).$$

For a line of, say, L miles in length, the amplitude of the arriving current is a maximum if $\sqrt{l'/k'}=\frac{1}{2}rL$. In fact, the arriving current is the sending current divided by ϵ. It will be found that in practice we never have so small a value of h as this gives, and we generally try to make h as small as possible. We can approximate to the above conditions by inserting contrivances at equal distances in the line. I will take a few examples. I prefer just now to consider a cable in which I have recently taken an interest: $r=18$ ohms per mile, $k=0{\cdot}055\times10^{-6}$ farad per mile, $s=0$, $l=0$. I take q to be 5,000 (that is, a frequency of 800).

1. This cable with no contrivances, $h=g=\sqrt{kqr}/2=0{\cdot}04975$. So that if x is 1 mile, $\epsilon^{-hx}=0{\cdot}9513$. That is, there is an attenuation of 5 per cent. per mile.

2. Let $l'=l=0$. That is, there is neither inductance nor capacity inserted in the line. Now let there be an inductance leak to earth which causes k' to be $0{\cdot}01375\times10^{-6}$. Then $h=g=\sqrt{k'qr/2}=0{\cdot}024875$, so that $\epsilon^{-h}=0{\cdot}97513$, or there is an attenuation of 2·55 per cent. per mile. The approximation to this is by an inductance to earth of L henrys per mile, where $0{\cdot}055\times10^{-6}-1/Lq^2=0{\cdot}01375\times10^{-6}$, or L=0·972 henry. When I use an inductance to earth I generally prefer to put it in series with a condenser. Thus, instead of an inductance of 0·972 henry, I would use an inductance of 1·012 henrys in series with a condenser of 1 mfd. This enables the line to be tested more easily. Instead of an inductance leak of 0·972 henry per mile we may insert $0{\cdot}972/m$ henry every m miles. As m gets greater the discrepance from the continuous conditions gets greater. The problem to be solved, later, is in all cases to find the discrepance for a particular value of m and what therefore is the most convenient distance by which contrivances ought to be separated.

3. Suppose $l'=-0{\cdot}09112$ and $k'=-0{\cdot}0125\times10^{-6}$. These values will cause c to be a maximum if the distance is 300 miles. It will be found that they mean a capacity of $0{\cdot}439\times10^{-6}$ farad per mile in series with the line and an inductance leak of 0·5925 henry per mile. Here $g=0{\cdot}16775$ and $h=\frac{1}{2}\sqrt{k'/l}=0{\cdot}00033$. This means an attenuation of 0·333 per cent. per mile when q is 5,000. Now when q is taken as 3,000 or 4,000 the attenuation is 0·64 or 0·53 per cent. per mile.

The approximation to these conditions is (*a*) a contrivance every m miles consisting of a capacity of $0{\cdot}439/m$ microfarad in series with the line and an inductance leak of $0{\cdot}5925/m$ henry; or (*b*) a contrivance every m miles consisting of a capacity of $0{\cdot}439/m$ microfarad in series with the line between two inductance leaks each of $1{\cdot}185/m$ henrys; or (*c*) a contrivance every m miles consisting of two condensers in series, each of the capacity $0{\cdot}878/m$ microfarad, the point of junction being put to earth by an inductance of $0{\cdot}5925/m$ henry. It will be found that as m is smaller and smaller the line with detached contrivances approximates more and more to the line with continuous properties.

Detached Contrivances.—Suppose we have contrivances at the equidistant places A, B, &c., m miles apart. There is a contrivance whose terminals are A and A_0, another whose terminals are B and B_0, &c. Between A_0 and B we have the standard cable. Let the currents in the line at A, A_0 and B be c, c_0 and C. Let the voltages at these points be v, v_0 and V. Let $V/C=v/c=\rho$. Knowing the nature of the contrivance we can calculate v_0 and c_0 from v and c. It is also known that

$$V=v_0\cosh mn+\frac{r+lqi}{n}c_0\sinh mn,\quad C=c_0\cosh mn+\frac{n}{r+lqi}v_0\sinh mn,$$

where $n=\sqrt{(r+lqi)(s+kqi)}$. Putting V/C or ρ equal to v/c, we have a quadratic to calculate ρ and therefore V and C.

I am in the habit of writing $c=1$, meaning $c=\sin qt$, and then $v=\rho$. Whatever the contrivance may be, $\frac{V}{C}=\rho=\frac{\alpha+\beta\rho}{a+b\rho}$, where α, β, a and b are given in value; they are usually complex unreal quantities. Solving for ρ and finding C we have two answers, C_1 and C_2 say. In general $C_1C_2=1$, and if $\frac{1}{2}(a+\beta)$ be called P, $C=P\pm\sqrt{P^2-1}$. Now P is very easily evaluated, and therefore C.

Examp'e.—(1) If our contrivance is a resistance r_1 in series with the line $c_0=c=1$, $v_0=r_1+\rho$. Thus if r_1 is an ohmic resistance R in series with a capacity K and an inductance L, $r_1=R+Lqi+1/Kqi$. This is a very simple case, the simplest form of which is that of Mr. Pupin, a mere inductance coil in the line. The trouble in such a case is that the whole telephonic current passes through the coil and there is considerable ohmic loss of energy. It is to be remembered that the value of R to be taken in any such case may be many times the ordinary resistance, because c^2R is taken to be the total loss of power, and this is due to hysteresis, eddy-currents, &c., as well as mere ohmic loss.

2. Again, taking a case already mentioned; the contrivance consists of two equal resistances r_1 in series with the line and a resistance leak to earth r_3 from the point of junction of the other two. It is easy to show that $c=1+\frac{r_1}{r_3}+\frac{\rho}{r_3}$ and $v_0=2r_1+\frac{r_1^2}{r_3}+\rho\left(1+\frac{r_1}{r_3}\right)$, and it follows that

$$P=\left(1+\frac{r_1}{r_3}\right)\cosh mn+\left(\frac{n}{r}r_1\left(1+\frac{r_1}{2r_3}\right)+\frac{1}{2r_3}\frac{r}{n}\right)\sinh mn.$$

It may be well to work out one example. In the above-mentioned cable $r=18$, $k=0{\cdot}055\times10^{-6}$, $s=0$, $l=0$; take $q=5{,}000$,

$$n=\sqrt{rkqi}=0{\cdot}07036\ (45^\circ),\quad \frac{n}{r}=0{\cdot}003909\ (45^\circ),\quad \frac{r}{n}=255{\cdot}8\ (-45^\circ).$$

Let us place contrivances at $m=4{\cdot}263$ miles apart. I choose this distance because $mn=0{\cdot}3$ (45°), and this happens to be given in Prof. Kennelly's table, which tells me that

$$\cosh mn=1{\cdot}0007\ (2^\circ.35'),\quad \sinh mn=0{\cdot}29994\ (45^\circ.51').$$

To imitate the continuous case given above we need an inductance leak of 0·5925 henry per mile or $L=0{\cdot}5925\div4{\cdot}263$ every 4·263 miles. Hence $r_3=Lqi=694{\cdot}7i$. Now r_1 is a condenser of capacity $K=\frac{0{\cdot}878}{4{\cdot}263}10^{-6}$, so that as $r_1=1/Kqi$, $r_1=-971{\cdot}13i$. Inserting these values in the above formula, I find $P=-0{\cdot}05384-0{\cdot}068078i$, and $C=1{\cdot}057\ (183^\circ.54')$ or $0{\cdot}946\ (-183^\circ.54')$. That is, there is an attenuation or increase of 5·5 per cent. in 4·263 miles or 1·3 per cent. per mile. Observe how different this is from the effect of the continuous distribution.

As another case, a most important one, consider the standard subterranean cable $r=88$, $k=0{\cdot}05\times10^{-6}$, $s=0$, $l=0$.

I. Without contrivances $h=g=\sqrt{rkq}/2$. If $q=5{,}000$ (a frequency of 800), $h=0{\cdot}1049=g$. There is an attenuation of 11 per cent. per mile. It is to be observed that notes of frequencies 1:2 are attenuated in the proportion 1: $\sqrt{2}$. This is probably good, because it is known that the graver notes of speech need to be of greater intensity for distinct hearing. But the changes in phase are also as 1: $\sqrt{2}$, whereas for good hearing they ought to be as $\sqrt{2}$:1. Using this cable with no contrivances it is found in practice that there is good telephonic speech to a distance of 40 miles. When $q=5{,}000$ a current 1 is reduced to 0·015 or $\frac{1}{66}$ of itself in 40 miles. If $q=6{,}000$ (a frequency of 930) a current of 1 is reduced to 0·01 with a lag of 2·3°; whereas if $q=4{,}000$ (a frequency of 640) a current 1 is reduced only to 0·0238, but it has a lag of 215°. In fact, the two lags in actual time are as 22 to 29. If, then, we find such attenuations and lags in any case we may infer that good telephone speaking is possible.

II. I will first give examples of a tuned circuit, that is, very perfect transmission of one musical note of frequency 800. Keeping to the contrivance which has two condensers in series, each of capacity K in the line and an inductance leak of L henrys to earth from the point between the condensers, it is easy to write out the general expression for P in terms of m and r_1 and r_3 (at all events when mn is small), and it may be studied. Now for any particular m find the values of r_1 and r_3 which will cause P to be nearly 1 (0°) and therefore C to be nearly 1 (0°). I have already explained that we have no right with the above formulæ to get a really constant current like this, but we have a right to approach it very nearly. If $m=1$ mile, then K=0·5917 mfd. and L=0·8324 henry. If $m=2{\cdot}755$ miles, K=0·2273 mfd. and L=0·3692 henry. Even when m is as much as 5·51 miles, a very considerable distance for such a cable, I find that I can use values of K and L which cause the attenuation to be comparatively small.

We see that by means of contrivances placed at considerable distances apart we can tune a long circuit so that it will transmit a current of one frequency, just as if the line were a mere ohmic resistance. I do not know whether practical men see great value

Digitized by Google

in having this power. It may be important to inventors. It is well, however, to say that when we have such a line, unless the contrivances are rather close together, the circuit is really a tuned one, tuned to a particular frequency and not good for the transmission of other frequencies.

III. Isolated contrivances. When m is so great that cosh mn and sinh mn are practically equal, calculations are particularly easy. Thus, taking the case in which $q=5{,}000$, $r=88$, $k=0{\cdot}05\times10^{-6}$.

We have

$$\frac{r}{c}=\rho=\sqrt{r/kq}\,i=593\ (-45^\circ)=419{\cdot}3\ (1-i)=\alpha-\alpha i=\alpha-\beta_1 i,\ \text{say.}$$

1. If in the middle of a very long line we merely insert an inductance leak to earth of L henry; $L=\frac{\alpha}{q}=\beta=0{\cdot}11725$ gives the best effect. This multiplies the received current by 1·414 and causes a lead of 45°.

2. An inductance of L=0·11725 henry in series with the line and a leak to earth which is a condenser of capacity $1\div\beta_1^2$ farads (in the present case 0·532 mfd.); this causes the current to be multiplied by 1·414 and to get a lead of 225°.

3. An inductance of 0·11725 henry in series with the line and no leak to earth. This multiplies the received current by 1·414 and it creates a lag of 45°.

IV. Returning to the contrivance consisting of two equal condensers in series with the line and an inductance to earth from the point between the condensers. For good telephonic speech it is evident that the inductance ought to be small, otherwise there is too much dependence on frequency; there is some tuning. We want k'/l' to be small and nearly constant and $k'l'$ to be small also. We cannot effect both these objects, but we can obtain fairly good speaking by compromise. Thus, let $k'=-0{\cdot}05\times10^{-6}$ and $l=-0{\cdot}128$, so that K=1/3·2 mfd. and L=0·4 henry. Thus if m is 1 mile, $r_1=-320i$ and $r_3=2{,}000i$. I find that if $q=5{,}000$, C=0·9704 (24°.3), it $q=4{,}000$, C=0·9647 (35°). This is, with a frequency 800 there is an attenuation of 3 per cent. and a lag of 24° per mile, whereas with a frequency of 640 there is an attenuation of 3½ per cent. per mile and a lag of 35°. We get practically the same results by continuous formulæ.

Practical men will now see their way to easy calculation of the effect of placing any kind of contrivance in a circuit, and I need not give any more examples. It is to be remembered that condensers suitable for telephonic purposes are very cheap, a few shillings per microfarad, whereas inductances are expensive. Also, it has to be remembered that when the whole telephonic current passes through an induction coil, its resistance becomes of very serious importance, for the cost of coils of similar construction is proportional to the 3/2 power of L/R if L is the inductance and R the resistance of the coil.

Appended to the Paper is a table of the values of sinh r (45°) and cosh r (45°) to supplement that published by Kennelly.

RAILWAY ELECTRIFICATION,

At the present time the subject of railway electrification is one of the most important topics in engineering circles. The following abstract of a lengthy discussion which took place a short time ago at a meeting of the American Institute of Electrical Engineers should therefore prove of interest to electrical engineers in this country. The discussion was in connection with a Paper by Mr. C. T. Hutchinson on "The Three-phase Installation in the Cascade Tunnel of the Great Northern Railway Co," of which an abstract appeared in our issues of January 14th & 21st.

President STILLWELL remarked that the three-phase system had been in use in Italy and in Switzerland for a number of years, and, since 1904 on what might be called a large scale, on the Valtellina line. From 1890 until recently but little attention had been paid in the United States to the practical application of the polyphase motor to railway purposes. It had received during that period careful study, but the conclusions reached were negative, so it was not introduced in commercial service. In the United States at the present time there were three different systems operating electric traction of the heaviest kind—namely, the direct-current, the single-phase and the three-phase systems. All these were doing their work not only successfully, but in a manner that showed a marked improvement over the steam locomotive operation that they had superseded. The steam railroad managements of the country were beginning to awaken, and were asking which was the best system for general railway work. It was here that one of the functions of the Institute came in. In the U.S.A. there was no government commission to decide general standard specifications and to pass on the claims of various systems before adoption, as, for example, in Germany. He was always glad, therefore, to have this subject presented, because there was nothing within the scope of the Institute that was of greater technical interest or that compared with it in commercial importance.

Mr. W. S. MURRAY, as a single-phase man in other fields, said that, so far as the Cascade Tunnel was concerned, he was heartily in agreement with Dr. Hutchinson's chosen method of electrification. The author stated that traction developed by motors of the three-phase type admitted of 3 per cent. or 4 per cent. greater adhesion than in the case where single-phase motors were used. Now, the single-phase motor was admittedly heavier than the three-phase motor of the same capacity, and, therefore, if it lacked adhesion in its torque developing characteristic, which statement was by no means accepted by all, the deficiency was taken care of by its excess weight. A frequency of 25 cycles was also applicable to single-phase installations, but it was true that the use of three-phase apparatus assured less costly generators. This saving, however, was offset in the case of single-phase installations by less costly switchboards. He agreed with Dr. Hutchinson that, in regard to mechanical clearance, ¼ in. was ample for all practical purposes, and that the yard proposition on two overhead wires was not practicable; this was true of main-line tracks where high speeds and many switches were involved. He supported the author's views in regard to simplicity, capacity and reliability of the induction motor, but regretted that its electrical characteristics did not conform to those required by the general traction problem. It was to the alternating-current series motor what the direct-current shunt motor was to the direct-current series motor. The direct-current shunt motor had disappeared for ever on all traction lines, and he did not believe that it could reappear under the cloak of alternating current.

Mr. E. B. KATTE thought the reasons for adopting a three-phase system over the whole mountain division were quite obvious, but he was surprised to note that this same system would probably have been used if only a 4 mile tunnel section was to have been considered. Without going into figures, it would seem that a direct-current system with storage batteries would have made unnecessary the use of steam locomotives in starting electric trains, and at the same time would have relieved the power station from the sudden inrush of current, thus securing better regulation at the water wheels. And further, by adopting multiple-unit control for the locomotives, two or more at the head of a train could have been operated with one-half the number of men. He asked the author why the earth wire was finally omitted. When the transmission line of the New York Central was designed, similar provision was made for an earth wire, but after further consideration it was left out, for the reason that the poles were of steel and each carefully earthed to a large copper place set in permanently wet ground, and it was believed that each pole would act as a lightning rod and thus protect the line. However, on the Great Northern line the poles were wooden and the insulator pins did not seem to have been earthed, consequently if an earth wire was ever necessary, these would appear to be conditions under which it would be most valuable.

Mr. BION J. ARNOLD was surprised at the excessive friction of the Mallet compound locomotives, given as an average of 46 lb. per ton. Ordinarily the friction load for steam railway trains was estimated at 6 lb. per ton on level straight track. This excessive friction was probably due to the greater number of cylinders, reciprocating parts and extra weight of the valve motion of these engines; and it indicated that some of the advantages of these immense engines were offset largely by this excessive friction. The author had adopted a method which gave him a single speed for his electric locomotives and resistance was used when starting. Such practice would not do in case the power were produced by a steam power plant on a railroad of any great magnitude, and a different conclusion would have to be drawn as to the method of control to be adopted in case the three-phase system were made applicable to a large railway system.

Mr. F. N. WATERMAN said there was one interesting property of induction motors which was not exhibited in the present instance, because only one train was operated—namely, the action of moving trains as flywheels to keep down the peaks or to minimise the fluctuations of output of the central station. This was illustrated on the Valtellina line. With only one train running the ratio of maximum to average ordinate of the output curve was about 3·5 to 1; the average run was short, requiring frequent acceleration. With four to six trains on the line the ratio of maximum to average output fell to 1·7 or 1·8 to 1, giving a load factor of 55 to 60 per cent. The reason why the ratio of maximum to average was a favourable as 3·5 to 1 with single-train operation was the employment of cascade control for most of the trains. The remarkably favourable results on the Italian State railways were unquestionably due to the peculiarity of induction motors that they ceased taking current if the frequency fell by the amount of their slip, and returned current if it fell to a greater extent. The water wheels driving these generators fell off in speed some 5 per cent. as full load came on, while the average slip of synchronously running trains was less than 1 per cent. Hence, as the shock of starting a train came upon the power house the frequency fell, and it had to fall only 1 per cent. entirely to relieve the station of other loads. A further fall would cause the moving trains to return energy to the line and help supply the starting current. This momentary relief of the station resulted in the high load factor noted. This property of induction motors should be of great value where a small number of trains was operated. Of course, relief of the power house by this means was only momentary; whether it would be of consequence at all in such a proposition as the author was dealing with was perhaps problematical. He had had some calculations made showing the effects of tandem control of three-phase motors in comparison with the series-parallel control

Digitized by Google

of the New York Central locomotives. It was impossible to include a computation for the single-phase locomotive, because sufficiently accurate information was not available. The table showed that the tandem control with two speeds—a method that left the entire equipment available for either kind of running—was at least not inferior to the New York Central locomotives, employing four motors and their three groupings, in respect of maximum draught on power house or total energy consumption, but was rather better. If handled on the basis of constant-current input, which was not the custom in direct-current practice in America, he believed the three-phase locomotive would show rather a noticeable advantage when the application of the three-phase motor to railroad work had received the same thorough study and development as given to the direct-current motor.

Comparisons of Three-phase and Direct-current Locomotives.

Type of locomotive.	Total train wght. (tons).	Net train wght. (tons).	Distance. Feet.	Time. Sec.	Speed max. miles per hour.	Kilowatts. max.	Kw.-hours.	Watt-hours per ton-mile. gross.	Watt-hours per ton-mile. useful
New York Central (weight 95 tons)	435	340	27,300	426	58·4	1,320	110·0	49·4	62·8
Valtellina 2 speed type (weight 68 tons)	408	340	27,300	426	58·5	1,660	104·0	49·1	59·4

New York Central.....	265	170	29,800	403	60·5	1,800	82·0	54·9	85·5
Valtellina 2 speed type	238	170	29,800	404	59·5	1,660	71·0	52·8	74·0
Valtellina 3 speed type	238	170	29,800	402	59·5	1,660	60·0	44·7	62·5

From a mechanical point of view he was much interested in the motors of the Italian State railways. The clearance used there between rotor and stator was 2 mm. (about $\frac{1}{12}$ in.), and the wear of the bearings in some 60,000 miles of operation was about 0·3 mm. The reason for such a result was that the collector rings were outside the bearings, leaving it only necessary properly to proportion the spiders to have virtually the entire interior of the rotor for bearings and lubricating means.

Mr. J. H. Davis compared the conditions at Cascade Tunnel with those encountered on the Belt Line Railroad of the Baltimore & Ohio, where direct-current electric traction had been used for 14 years—this being the first installation of electric locomotives for heavy traction purposes in the United States.

Mr. L. R. Pomeroy had obtained particulars of a road test of a Mallet locomotive over the section described in the Paper—namely, from Leavenworth to the Cascade Tunnel summit—a distance of 32·4 miles, with an average grade of 1·35 per cent. and a limiting grade of 2·2 per cent.; also from a neighbouring road having similar physical conditions, an actual coal record for a period of six months, of individual classes of locomotives, representing 156 locomotives making 1,382,092 miles, and consuming 174,121 tons of coal, as follows:—

No.	Class.	Engine-miles.	Tons of coal.	lb. per 1,000 ton-miles	lb. per engine-mile.
55	2-8-2 simple	291,070	33,418	191	230
6	2-8-2 compound	81,150	10,275	175	251
24	2-8-0 simple	299,036	33,931	345	227
71	2-8-0 compound	710,836	96,479	306	271
156	.....	1,382,092	174,121	...	...

Some figures of the test referred to were as follows: Distance, 32·4 miles; running time, 4 hours; total time, 7 hours; average speed, 8·1 miles per hour; coal used per trip, 23,000 lb.; coal per square foot of grate per hour, 74·03 lb.; coal per 1,000 ton-miles, 896 lb.; average weight hauled, 810 tons; average number of cars per train (all loaded), 21; average grade, 1·35 per cent.; maximum grade, 2·2 per cent.; indicated tractive force, 60,000 lb.; type of locomotive 2-6-6-2 (L2), Mallet; total weight of locomotive, 225 tons. From the foregoing data the speaker made a few deductions. A train with a trailing load of 2,500 tons over the section of road on which the test was made would require about 5,750 kw.-hour at the rail per trip. Assuming a modern steam generating station, the coal used per trip at 15 miles per hour would be about 5 lb. per kilowatt-hour (at the rail), or a total of 28,750 lb. With the same tonnage per train under steam conditions at 15 miles per hour three steam locomotives would be necessary. Increasing the speed of the steam train from 8·1 miles per hour to 15 miles per hour reduced the tonnage about 30 per cent. per locomotive, giving a total weight, including locomotive, of 725 tons per locomotive. The coal consumption of the three steam trains then became at 717 lb. per mile 68,832 lb., the difference in favour of electricity being 58 per cent. Taking a basis of 50 per cent., the speaker showed that the annual coal saving for the 156 steam locomotives would equal $348,242. As the Mallet type of locomotive claimed to be 30 per cent. better than the above locomotives, this amount might be reduced 30 per cent. to $243,769; adding the saving in water ($25,000) the net saving became $268,769. This amount capitalised at 5 per cent. represented $5,375,380, which sum alone, not figuring on other savings, such as train crews, reduction in train-mileage with the same tonnage, and the advantage of a great increase in capacity, showed that such a mountain section came very near being a situation where one could accomplish by electrification what was now impossible under steam conditions. Approximate figures from three railroads which showed separately in the annual reports the coal per locomotive-mile for freight and passenger service, based on the total coal for the year, gave the consumption per horse-power-hour as 12·30 lb., 12·86 lb. and 14·0 lb. for passenger service, and 9·64 lb., 11·20 lb. and 10·0 lb. respectively for freight service; while from individual road tests it was found that the coal consumption frequently was from 4 lb. to 8 lb. per horse-power-hour. It was not quite fair, therefore, to the electric side to base the comparative costs on a road test without adding a liberal amount to cover this "contingent" feature.

Mr. W. N. Smith thought the objection to two trolley wires was partly obviated by the slow speed of 15 miles per hour. In his opinion this was the salvation of the wheel-trolley contact system adopted. But even slow speed could not mitigate all the disadvantages of two trolley wires of opposite polarity. It was in respect to the trolley problem that the single-phase system was likely to be regarded as superior for some time to come. Future development in the perfection of the moving contact would probably be in the way of the wide roller type with pantagraph mounting, as distinct from the narrow trolley wheel or the sliding shoe; for the sliding shoe, widely used for high-speed work at the present time, seemed susceptible of further improvement, if wear and tear at high speeds and heavy currents were to be overcome. Speeds of 20 to 30 miles per hour might sometimes be thought advisable on a mountain grade of this type, and he suggested that the next locomotives to be built for this electrified section, or a similar one, would be fitted either with pony wheels or with side rods for coupling to motors placed on top of the frames, or possibly with both of these contrivances. The increased flexibility of locomotive design from the mechanical standpoint, which was consequent upon placing the motor on top of the frame and using side rods and jack shafts, and the general mechanical uniformity with the frames and running gear of existing steam locomotives, would make an electric locomotive appear more like a standard piece of machinery to the railroad operating man than had hitherto been the case. The great advantages would be the raising of the centre of gravity, the ready standardising of mechanical parts independently of electrical equipment, and the ability to use the same arrangement of frames and running gear for either direct-current, single-phase or three-phase motors. With such construction safe speeds were not limited to 15 miles per hour. Without it, track maintenance and liability to derailment might continue to be as disadvantageous to the electric locomotive at high speeds as they had been in the past. In spite of the objections that had been urged against the term "continuous capacity," as applied to railway motor specifications, the author apparently took it for granted that it was bound to survive; and it was to be hoped that its evident applicability to the specification of locomotive motors would lead to a more universal recognition of its appropriateness in specifying the smaller sizes of railway motors.

Mr. F. S. Denneen said that the chief reason for selecting the direct-suspension type instead of the more elaborate catenary type, now so popular, was the greater mechanical and electrical simplicity of the former.

Mr. W. I. Slichter mentioned that the principal characteristic which differentiated American from European railway installations was size. American trains were about three times as heavy as the European trains, and the heavy traffic over single-track roads required that every operation must be performed with the utmost reliability. In the locomotives under consideration, as the tractive effort had to be applied gradually, steadily and continuously, any scheme of double-speed connection, such as concatenation or changeable poles, was undesirable, as in these it was necessary to cut out at least a portion of the motors while the change was being made.

Mr. E. F. W. Alexanderson remarked that railway motors of the ordinary type were in most cases limited in capacity by the temperature rise in service; this was substantiated by the fact that there was allowed a higher temperature than that found economical with stationary machinery. The continuous capacity of such motors of the closed type was usually about one-third of the capacity for one hour, whereas the continuous capacity of the Great Northern motors with forced ventilation was 79 or 74 per cent. of the hourly capacity at 500 volts and 625 volts respectively. In attempting to meet the Great Northern requirements it was immediately apparent that a motor of any reasonable size would run too hot unless forced ventilation were used. It was naturally attempted to make the artificial cooling as efficient as possible by taking advantage of the structure of an alternating-current motor with distributed windings, thus bringing the air into intimate relation with the active parts. In order not to waste space in the length direction of the motor—which had already been encroached upon by the double gearing—the air was led through holes or channels running longitudinally through the core. This system of ventilation proved successful, and tests showed that the continuous capacity with forced ventilation was practically the same as the hourly rating on a standard basis without ventilation. The weight efficiency of the three-phate railway motor was often referred to. It might, therefore, be of interest to compare the Great Northern motor with two other well-known locomotive motors—the Detroit River tunnel locomotive (a freight locomotive of the same weight and mechanical design provided with four motors of the double-geared type), and the Simplon,

Digitized by Google

a well-known three-phase locomotive. In the accompanying table was shown the comparative figures for a stationary three-phase motor of the same dimensions. All three induction motors had practically the same armature peripheral speed, and the weight per horse-power was favourable. The Simplon motor was favoured by a small air-gap, but handicapped by being wound for high voltage. The comparison of the four-motor types showed a relative consistency and also indicated the great possibilities of the inductive motor for high-continuous output.

—	Detroit River tunnel, 600 v., d.c.	Great Northern, 625 v., 3 phase.	Simplon, 3,000 v., 3 phase.	Stationary motor, 550 v., 3 phase.

Mr. C. L. DE MURALT thought that what the author brought out principally was that the efficiency of the three-phase system was extremely high. There was no other system that would show the same efficiency under the same conditions. Some engineers claimed it was not good practice to use two trolleys. It was not an operating feature at all; it was a matter of suitable design and proper location of overhead line. Once these were taken care of, the road would operate with two overhead wires just as well as with one. There was hardly any difference in maintenance either, because the maintenance cost was made up of labour rather than of material.

Mr. C. TOWNLEY said that, with reference to uniform torque, their observations on single-phase locomotive performances did not support the view that the so-called pulsating torque of that motor was practically in evidence. The comment of a prominent steam railroad engineer on the question of constant speed was that the conditions which affected the operation of trains on schedules and which caused delays were many of them entirely foreign to any question of traction. Various and diverse influences caused delays, requiring trains to make up time if they were to be maintained on schedule. Therefore, an inflexible and a uniform speed was undoubtedly somewhat of a disadvantage, even though the running time and operating conditions indicated that ordinarily it was desirable to maintain a uniform speed when the trains were running.

Mr. C. P. STEINMETZ mentioned that, in addition to its use on a mountain division, another application of the induction motor would be for very high speed passenger service. At speeds of 50 or 60 miles an hour or above, the air friction produced a considerable part of the train resistance; there was a decrease of the difference between the power required to run on a level track at a constant speed and the power of acceleration, and, therefore, an approach to the same conditions as running on a mountain division. For general railway work, however, as at present carried out in America, the three-phase locomotive was not as well suited as the direct-current locomotive or the single-phase locomotive, for the reason that the direct-current series motor or the alternating-current commutator motor could directly replace the steam locomotive in present railway operation, while the three-phase induction motor locomotive was not at its highest efficiency, when operating on a railway system under existing conditions. The method of operation must be rearranged to a constant-speed service. Whether the constant-speed operation of the railway would be disadvantageous, or advantageous, over the present variable-speed method, required further consideration.

Mr. F. J. SPRAGUE (communicated) remarked that the Cascade Tunnel installation was one of three in America of almost identical requirements, but each was characterised by a different electrical system. Two, the Sarnia single phase and the Cascade three phase, were in operation, while the Detroit Tunnel direct-current locomotives had been fully tested. In each case the steam locomotive could only be used under the maximum disadvantages. None of these installations represented normal trunk line requirements. He had for nearly three years made a study of such a trunk line, presenting, perhaps, the most difficult operating problem he had encountered. He referred to a stretch of nearly 140 miles on the Sacramento Division of the Central Pacific Railroad, over the Sierra Nevada Mountains. The section was normally single tracked, with sidings every few miles, raising the aggregate trackage to something over 200 miles. The physical conditions were such as to present extreme difficulties to double tracking, although second tracking was being added for a part of the distance. There were nearly 32 miles of snowsheds and tunnels, and in winter the snowsheds formed practically continuous tunnels. The grades were severe, there being a rise of about 7,000 ft. in 83 miles in one direction, with a ruling grade of 2·4 per cent., and the amount of curvature was startling. Over this division practically the entire freight and passenger traffic from the Union Pacific Railroad for Central California passed. Freight trains, often over ½ mile in length, and with 2,000 to 2,500 tons trailing load, were operated in both directions. These trains required as many as four consolidated locomotives, or two of the heaviest Mallet compounds. The running speed was sometimes as low as 7 miles an hour, and the schedule speed for the division was seriously interfered with by opposing traffic. Coupled with this freight operation was passenger operation in both directions, in trains up to nearly 400 tons trailing load, way trains, "limited" Pullmans, and fast mail trains, operating at double the freight speeds, and with coasting speeds as high as 50 miles an hour. This division was approaching the limit of steam capacity, especially when considered in relation to the balance of the system, and the question was whether such a division could be operated electrically, and, if so, what could be gained thereby. Would the object be economy in fuel? Such alone would not warrant electrification, although the general line of investigation of railroads operated by electricity showed about 50 per cent. in coal economy. If carried out, electrification would be primarily for the purpose of increasing capacity, and thereby effecting ultimate economy. The investigation of the possibilities of electrification on this road had been conducted on a plan somewhat different from that ordinarily taken. It was not deemed wise first to decide upon a system, but rather to ascertain the costs of locomotives by various systems which could perform a service determined as essential to effective operation, and then to collate all the facts, advantageous and otherwise, affecting capital cost and cost of operation, after which the best system to meet the existing conditions could be determined. If asked what system would probably be indicated, he must frankly say that he did not know. That electrification was possible he did know, and that such could be successfully carried out he did not doubt, with increased capacity and general economic results.

Mr. MAX TOLTZ took exception to the author's figures for the rail resistance, given as 6 lb. per ton. Dynamometer tests gave 6·5 lb. to 14·25 lb. per ton. In the tunnel, with its soot and wet rails, the resistance used to be over 10 lb. per ton. The rail resistance of the Mallet locomotive was stated to be 47 lb. per ton, computed from ammeter readings. This figure was much too high, and was probably due to the air pump action of the pistons in the cylinder.

Mr. C. T. HUTCHINSON, in reply, merely answered the questions that had been asked. The earth wire was omitted, as there was no lightning on that side of the mountain. In regard to the high frictional resistance of the Mallet locomotives, the tests were carefully made by competent observers, and he was sure were accurate expressions of the conditions that existed. He did not pretend that the internal losses of the Mallet, when operating under its own steam, were represented by those figures; there was no direct comparison between the two conditions.

SHORT-CIRCUIT LOSSES IN ALTERNATING-CURRENT COMMUTATOR MOTORS.

BY A. FRAENCKEL, DR.ING., AND B. J. M. LANE, B.SC.

Summary.—Results of experimental researches on the losses due to the short-circuit currents in alternating-current commutator motors are given. These show a rapid decrease of the loss with increasing speed, other conditions being equal. An explanation of this phenomenon is given, and oscillograms are shown from which the decrease of the short-circuit current with increasing speed, and for a given short-circuit E.M.F., is deduced. The influence of the short-circuit currents on the line pressure and current is illustrated.

Since alternating-current commutator motors have been in use much trouble has been experienced owing to the currents which are induced by the pulsations of the main field linked with the armature coils undergoing commutation. These currents not only cause sparking at the brushes and give rise to considerable losses, but they also cause a phase displacement between flux and current, and consequently diminish the torque of the machine for a given current value.

A large number of devices have been designed in order to diminish these currents, the chief tendency being towards the use of commutating fields. By these means the short-circuit currents may be reduced to a limited extent, and heavy sparking avoided; but since a commutating field of proper magnitude and phase cannot be obtained for all speeds and working conditions, there still remain at nearly all load conditions short-circuit currents causing additional losses.

An experimental research on these losses was published by Prof. Bragstad and Mr. S. P. Smith in THE ELECTRICIAN, 1906 (Vol. LVII., p. 996). In this Paper it is shown how the losses depend upon the E.M.F. induced in the short-circuited coils by the pulsations of the main field and the drop of pressure between brush and commutator, the experiments having been carried out for one definite armature speed. The losses were determined by taking the difference between the power delivered from the mains to the exciting coil, firstly when no brushes were on the commutator, and secondly when the brushes were on and placed in the neutral zone. In both cases the armature E.M.F. in the axis of the stator exciting winding and due to flux pulsations had the same value.

In carrying out similar experiments to those mentioned, the

Digitized by Google

authors of the present Paper found that the losses not only depend upon the E.M.F. induced in the short-circuited coils, and upon the brush contact resistance, but that for a certain brush resistance and induced E.M.F. they vary to a great extent with the speed of the machine. The present investigation is intended to explain this phenomenon, and includes a series of experimental results and oscillograms that have been obtained.

Firstly we will consider theoretically the phenomena that occur.

Theoretical Considerations.- For the sake of simplicity, let us initially deal with the case in which *the brush width is equal to that of one commutator segment*, so that for a parallel winding only one coil can be short-circuited, or for a series winding p coils, p representing the number of pairs of poles.

The differential equation for the short-circuit is

$$e = ri + L\frac{di}{dt},$$

where e = E.M.F. induced by the main field,
i = current in the coil,
r = total resistance of circuit,
L = self-induction coefficient of the coil for the stray flux.

While the self-induction coefficient does not vary much, and may practically be regarded as constant, the resistance r varies greatly with the relative position of brush and segments. In fact, r consists of three parts, the resistance of the coil R_s, the resistance of the two connectors between the coil and the

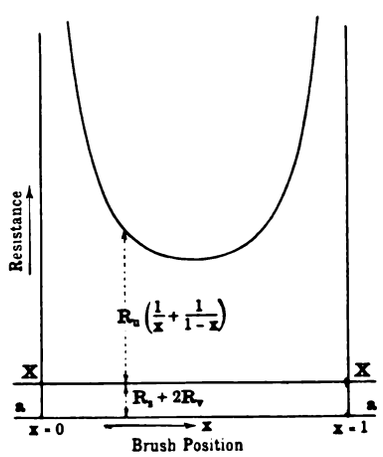

Fig 1.

commutator and the contact resistance at the brush surface. The latter consists of two parts, corresponding to the two segments 1 and 2.

Let R_K = specific brush-contact resistance,
F_u = contact surface between brush and commutator,
$R_u = \frac{R_K}{F_u}$ = contact resistance for total brush surface,
$F_{u1} = x \times F_u$ = the fraction of the brush surface covering segment 1,
$F_{u2} = F_u - F_{u1} = F_u(1-x)$ = fraction of brush surface covering segment 2,

The total resistance is thus

$$r = R_s + 2R_r + R_u\left(\frac{1}{x}+\frac{1}{1-x}\right),$$

where x varies from 0 to 1 for the different positions of the brush on the segments. *Supposing now that the armature is at rest* so that x is constant, and that the induced E.M.F. varies according to a sine law; then, if R_u and L be regarded as constant, the short-circuit current will also be a sinusodial function of time and vary with the same frequency as the induced E.M.F. Actually the E.M.F. $L\frac{di}{dt}$ for the line frequency is so small compared with the ohmic drop of voltage that its influence on the phase and magnitude of the current may be neglected and the latter may be regarded as being in phase with the induced E.M.F.

Thus, if E is the effective value of the induced E.M.F., the loss due to the current in the short-circuited coil is

$$\frac{E^2}{R_s + 2R_r + R_u\left(\frac{1}{x}+\frac{1}{1-x}\right)}.$$

For the different positions of the brush the resistance $R_u\left(\frac{1}{x}+\frac{1}{1-x}\right)$ varies as shown in Fig. 1, being infinite for $x=0$ or 1 and a minimum for $x=\frac{1}{2}$, the minimum value being $4R_u$. If we plot a second abscissa, $a-a$, whose distance from the first is equal to R_s+2R_r, then the ordinates between $a-a$ and the curve give values for the total resistance. Thus, for the different positions of the brush the losses will be shown by a curve having the same form as that shown in Fig. 2.

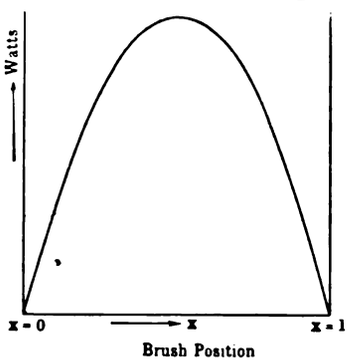

Fig. 2.

If the value R_s+2R_c is small, then the loss may be written in the form $\frac{E^2}{R_u}x(1-x)$, and in this case the curve in Fig. 2 will be a parabola. Thus it is seen that for different positions of the brush at standstill the losses vary considerably, the mean value being about two-thirds of the maximum.

It may be noted that the supposition that the brush contact resistance remains constant is not correct, as we shall see later on. However, for an analytical treatment no other supposition is practicable.

If now the armature rotates, the short-circuit of every individual coil lasts for only a short time, T, which is determined by the width b of the brush and the circumferential velocity of the commutator v_K. $T = \frac{b}{v_K}$. During this short time the E.M.F. induced in the short-circuited coil by the field pulsations varies from $e_1 = E_{max.} \sin wt$ to $e_2 = E_{max.} \sin w(t+T)$, as shown in Fig. 3; and, since T is a small fraction of the time of

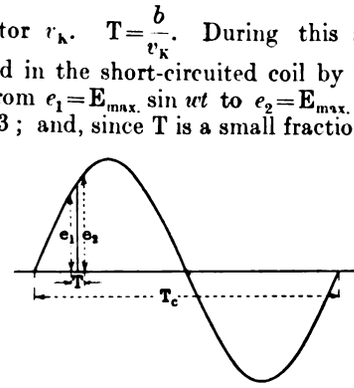

Fig. 3.

the period T_c, we may regard the induced voltage as being constant over the short-circuit period and equivalent to the mean value of e_1 and e_2. The short-circuit current will in this time increase from zero to its maximum value, and fall to zero again, having thus a far higher frequency than when the armature stands still. Consequently the effect of self-induction in this case cannot be neglected. If we had only ohmic resistance the current would follow the same law as in the case of the armature being at rest and the brush gradually brought into different positions with respect to the segments, so that the losses would follow the same parabolic law, the maximum loss taking place at the middle position of the brush with respect to two segments. The maxima of the different currents would follow a sine wave according to the sine wave of the induced E.M.F., and the mean loss would remain constant. The effect of

Digitized by Google

self-induction is that the currents will increase more slowly, and will not be able to reach their maximum values when the brush contact resistance is a minimum—*i.e.*, after half the time of short-circuit has elapsed. When the currents have reached their maxima, then the contact resistance is already higher. Consequently the maximum currents and the losses will decrease. In order to show this effect we must integrate the differential equation.

Let t represent the time from the beginning of the short-circuit. Then $t = Tx$, where x has the same meaning as before, and

$$r = R_s + 2R_c + R_u\left(\frac{1}{x} + \frac{1}{1-x}\right).$$

The E.M.F. of self induction $= L\frac{di}{dt} = L\frac{di}{T dx}$,

and so $$e = i(R_s + 2R_c) + R_u\left(\frac{1}{x} + \frac{1}{1-x}\right)i + L\frac{di}{T dx},$$

or $$\frac{di}{dx} + \frac{i(R_s + 2R_c)T}{L} + \frac{iR_uT}{L}\left(\frac{1}{x} + \frac{1}{1-x}\right) = \frac{eT}{L},$$

where e, as shown, may be regarded as constant and equal to

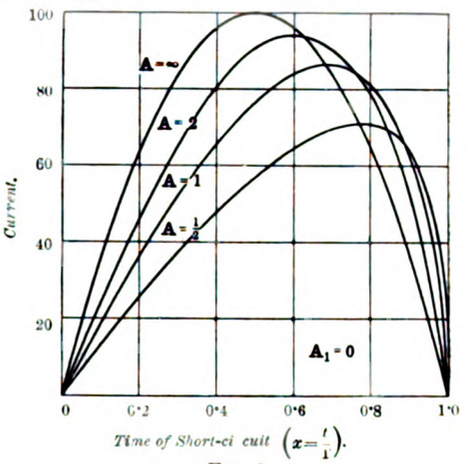

FIG. 4.

the mean of the two momentaneous values at the beginning and at the end of the short-circuit.

Let $$\left(\frac{R_s + 2R_c}{L}\right)T = A_1$$

and $$\frac{R_uT}{L} = A.$$

then $$\frac{di}{dx} + i\left\{A_1 + A\left(\frac{1}{x} + \frac{1}{1-x}\right)\right\} = \frac{eT}{L}.$$

The solution of this equation is*

$$i = \epsilon^{-A_1 x}\left(\frac{x}{1-x}\right)^{-A}\int_{x=o}^{x=x}\frac{eT}{L}\epsilon^{A_1 x}\left(\frac{x}{1-x}\right)^{A} dx.$$

where ϵ is the base of the natural logarithm. The value of i may be determined by a point to point method if values for A and A_1 are assumed, and we take the different values of x from zero to unity. A and A_1 are proportional to the time of short-circuit, or inversely proportional to the speed. A number of curves have been calculated, firstly when $R_s + 2R_c$ was neglected—*i.e.*, $A_1 = 0$, and secondly when $R_s + 2R_c = \frac{1}{2}R_u$, or $A_1 = A/2$. The curves in Fig. 4 correspond to a constant value for e, and are calculated for values $A = \infty$ (standstill), $A = 2$, $A = 1$ and $A = \frac{1}{2}$. They represent conditions for the first case, while corresponding curves are shown in Fig. 5 for the second case. From these curves the loss at any moment may be calculated, since this is equal to ri^2, r being the instantaneous value of the total resistance. If the mean loss W over the short-circuit period is plotted as a function of $\frac{1}{A} = \frac{L}{R_uT} = \frac{L}{R_u}\frac{v_k}{b}$, it will be seen how the loss decreases with the speed. This is shown in Fig. 6. For an infinite speed the loss would be nil.

* "Electrical Review," 1900, p. 211. Arnold Die Gleichstrommaschine, Bd. I., p. 419.

It is, however, to be expected that the actual losses will decrease more rapidly than those determined from the calculation, since the brush-contact resistance is not constant, but increases with decreasing current-density. As seen from the calculation, the maximum current and the corresponding density decrease with increasing speed. If now the higher resistance corresponding to the smaller density is taken into account, the maximum current will be less than that calculated, and the total loss diminished.

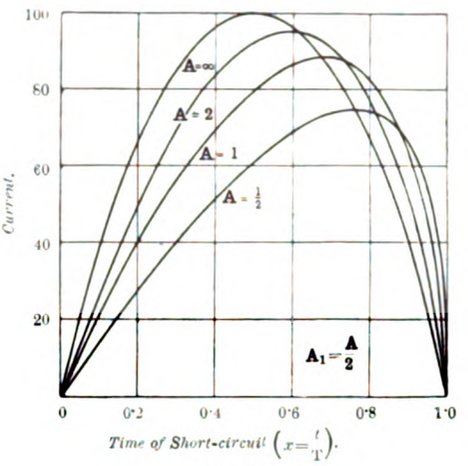

FIG. 5.

Considering now the cases where *the brush width is greater than that of one segment* and more than one coil are simultaneously short-circuited, the mutual induction must be taken into account. To treat these cases analytically would lead us to extremely complicated equations. However, we may consider them simply in a general way as follows: The internal currents in consecutive coils are displaced by an interval, T_1, corresponding to that which one segment requires to pass a given point, T_1 being determined by the width β of the segment and the circumferential velocity v_K of the commutator. $T_1 = \frac{\beta}{v_K}$. If we assume $\beta = b/2$, T_1 will be just half the short-circuit time of one coil, and while the internal current in one coil increases, the current in a neighbouring coil decreases, and vice versa. Thus the resultant E.M.F. induced by self and mutual induction does not vary with the period of the current in the coil, but pulsates with a higher frequency depending on the time T_1, the resultant being less than the E.M.F. due to self-induction alone. The result is qualitatively the same as in the case considered previously, with the exception that the apparent self-induction is smaller.

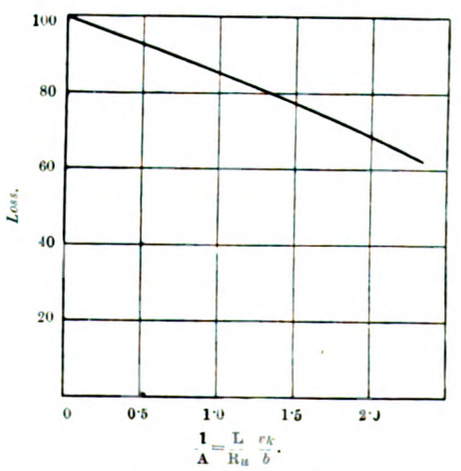

FIG. 6.—CALCULATED LOSS-CURVE FOR A CONSTANT BRUSH CONTACT RESISTANCE.

(*To be concluded.*)

SOME PHYSICAL PROPERTIES OF CRYSTALLINE SILICON.*

BY C. I. ZIMMERMAN.

It has been estimated by Clarke† that the element silicon constitutes 28 per cent. of the earth's crust. It exists in the form of its oxide, SiO_2, and this oxide constitutes 60 per cent. of the earth's crust. The importance of knowing the various properties of silicon, which can now be obtained in a relatively pure state in any quantity desired, cannot, therefore, be under-estimated. Not only might such information be of great value in finding valuable applications for the element, but it would probably lead to the correlation of many properties which the various elements and many compounds have in common.

The author then gives a brief summary of the various physical properties of this element, including its atomic weight, specific gravity, molecular state, tenacity, tensile strength, melting point, vapour tension, specific heat, optical properties, and goes on to discuss its magnetic and electrical properties as follows:—

St. Meyer‡ published some data on the magnetic behaviour of silicon. For all practical purposes it is non-magnetic. Silicon-iron alloys will decrease in magnetic susceptibility until the silicon content increases to 30 per cent. Above 30 per cent. of silicon, the silicon-iron alloys are practically non-magnetic. The electrical properties nad constants of silicon are exceptionally interesting because they are quite different from metallic conductors.

For instance, as regards thermo-electric properties Heath§ found that the junction of silicon and metals exhibits high thermo-E.M.F.s when heated. The magnitude and the direction of the E.M.F. generated will vary greatly in different specimens. Sometimes the current will flow in one direction across the hot junction and sometimes in the opposite direction. A single specimen may have positive and negative spots. This peculiar ability of a given substance to exhibit high thermo-electric forces in different directions at the contact with a metal or other conductor is not new, nor is it characteristic of silicon alone. It is quite a common phonomenon among mineral substances, and was investigated to some extent 25 years ago. Miss Francis G. Wick¶ and Dr. L. W. Austin have published some results on the thermo-E.M.F.s of silicon-metal contacts. They have stated that the usual direction of current flow is from silicon to copper through the hot junction. My own observations are just the reverse. The usual direction is from the copper to the silicon across the hot junction in a copper-silicon couple. I have tested this out on 40 or 50 different specimens of silicon which covered a wide range of physically and chemically different samples. I have also tried a number of alloys of silicon against a metal and have found that in nearly all of the cases the silicon was the positive side of the hot junction. The few specimens which did not follow my above described usual thermo-electric direction at ordinary temperatures, reversed their effect when the temperature of the silicon itself was raised considerably above the temperature at which the first observation was made. There was no reversal of direction in what I have called my normal specimens even when they were raised to a very much higher temperature than that which reversed the abnormal specimens. Further work on this line is in progress.

The characteristic unilateral or asymmetric conductivity which is observed at the contact surface between almost any two heterogeneous conductors is quite marked at the contact surfaces between silicon and metals. The current will pass across a silicon-metal junction much more readily in one direction than in the other. If the area of contact between silicon and a metal be varied the degree of unilateral conductivity for a given current flow will also vary. Hence if an electric circuit contains a piece of silicon held between two metal contact pieces, and if the areas of contact on each side of the silicon are different, that circuit will be a unilateral conductor. If an alternating current be then passed through this circuit which possesses asymmetric or unilateral conductivity, there will be a tendency to stop one half-wave and to pass the other half-wave. G.W.Pickard* was probably the first person to note that this effect could be utilised for wireless telegraph waves when silicon was one of the rectifying elements.

Extensive use of the silicon rectifier has been made in wireless telegraphy.† By a proper disposition of silicon rectifiers and of electrical condensers the energy of the short oscillatory trains of waves caught by an aerial can be stored in the condensers and subsequently discharged through a telephone receiver or through a galvanometer. Without rectification and without any means for storing the energy caught by the aerial the telephone receiver will not detect the waves. The condenser may be the aerial itself, or the telephone receiver coil. I have constructed some exceedingly sensitive wireless receiving circuits based upon the use of two or more of such crystal rectifiers with electrical condensers. Ordinarily only one such rectifier is used in commercial receiving circuits, and in such cases only a part of the energy of the oscillatory waves can be detected. The direction of the first half-wave of a strongly damped oscillatory train makes a great difference in the sensitiveness of a receiver containing only one silicon detector or rectifier. In this case much of the energy and also the highest E.M.F. of the damped waves comes in the first pulse. There is no thermo-electric action in the silicon detector. It is an interesting phenomenon, still to be explained, that the thermo-electric and rectifying actions of silicon-metal contacts and other

similar "crystal rectifiers" are usually such that the current flows through the rectifying contact in opposite directions in the two different cases. No doubt there is a simple explanation for this relation. Just as there are numerous substances which, when placed in contact will produce high thermo-electric forces when the junction between the two of them is heated, so there is a long list of substances which show a marked rectifying action like that which silicon exhibits. Carbon and tellurium show these thermo-electric and rectifying effects to a marked degree when in contact with other conducting substances. The list of conducting mineral substances which show this same effect is too long to be given here. Almost all of them show this to a more or less marked extent.*

When a current of electricity flows across a conducting silicon plate, which lies perpendicular to the direction of a strong magnetic field, the current in the plate will take a different course than when the strong magnetic field is not present. The path of the current tends to be rotated more and more as the magnetic field increases. In silicon this effect is quite marked.† It varies greatly with different samples of silicon and is roughly related in magnitude to the thermo-electric forces. Dr. Smith‡ has investigated the Hall effect quite extensively in silicon and other substances. In silicon he finds the Hall effect is a reversible affair, like the thermo-electric and rectifying properties and that they are closely related.

The electrical resistance of silicon also shows some exceptionally varied and interesting results. Two years ago Dr. C. P. Steinmetz§ in a lecture on "Conduction," gave some results on the relations between temperature and electrical resistance. He classified electrical conductors in a general way and stated that the resistance of certain specimens of cast silicon seemed to give an intermediate link between pyro-electrolytic and metallic conduction. Miss F. G. Wick‖ investigated the electrical resistance of some rods of silicon, similar to those which Dr. Steinmetz discussed. The results showed that cast silicon varied widely in its resistance characteristics in inffierent specimens. Some specimens showed a negative temperature coefficient through the range of temperatures which they studied, whereas other specimens showed a temperature coefficient which was at first positive and afterwards negative, and still others showed a change from negative to positive and then back to negative characteristics. Cast silicon rods were used in their measurements In Figs. 2 and 3 are shown curves plotted from experimental data which I have obtained from two specimens of silicon rods which were cut from homogeneous masses of slowly cooled, relatively pure and coarsely crystallised material. The temperature range covered was 190°C. to 800°C. The composition of these rods I give below:—

Rod No. 1. Impurities present.		Rod No. 2. Impurities present.	
Fe	0·32%	Fe	—
Al	0·14%	Al	—
C	trace	C	—
Ca, Mg, Mn	trace	Ca, Mg, Mn	—

In Figs. 2 and 3 there exists a cubic relation between the co-ordinates of the curves. In order to show this cubic relation more plainly I have drawn two curves in Fig. 3 from the equation of a cubic curve having the formula

$$y = m(K^2x - x^3)$$

In curve 1, $m = 0{\cdot}02$ and $K^2 = 30$. In curve 2, $m = 0{\cdot}02$ and $K^2 = -30$.

In curve 1 of Fig. 3 the factor K is equal to the horizontal distance between the centre of the cubic curve and the points at which the curve cuts the axis. The cause of the marked difference in the specific resistance of the two rods is not yet definitely known. It may be due to the difference in the chemical composition alone, but it is probably due to a difference in the physical condition of the molecular aggregates in the two samples.

COMMUTATION PHENOMENA AND MAGNETIC OSCILLATIONS OCCURRING IN DIRECT-CURRENT MACHINES.*

BY G. W. WORRALL, M.SC.

(*Concluded from page 185.*)

Summary.—In the first part of this Paper the author, after discussing the theory of commutation, describes a research on the influence of contact resistance, speed, commutating E.M.F. and width of commutating pole on commutation, the phenomena being studied by means of the magnetic oscillations recorded by search coils on the pole shoes. The cause of the difference in behaviour of the positive and negative brushes is also investigated. The latter portion of the Paper is devoted to an examination of the magnetic oscillations occurring in various parts of the machine.

Influence of Speed on Commutation.—It has already been pointed out that the natural period of commutation is but slightly influenced by the speed. The reason for this may be seen from the following considerations: At a given time after the commencement of short-circuit the contact resistance to the forward segment is increased, while that to the rear segment is reduced by an increase in speed. Such a change in the resistance will diminish the natural period of the coil, but not in proportion to the speed, while the available period is diminished in proportion to the speed, and the ratio of the available to the natural therefore diminishes as the speed increases. At a certain critical speed therefore the ratio is unity, and this is the critical sparking speed. Fig. 11 shows a series of records of the oscillations occurring in coil 5 P on the pole-shoe obtained by varying the speed of the machine. The negative peak moves to the left as the speed is diminished, and hence occurs earlier. At a speed of 640 revs. per min. the peak occurs just before the contact mark, which latter was adjusted to the commencement of the short-circuit;

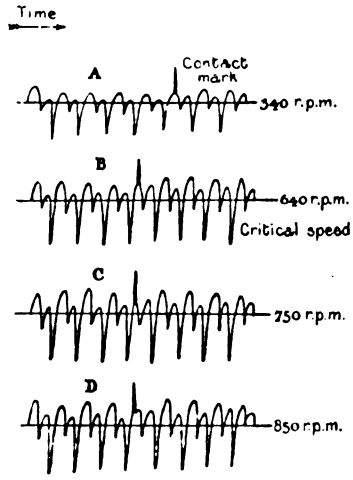

FIG. 11.

hence at this speed commutation was completed by a current rush, and when the speed exceeded this value the natural period exceeded the available and sparking took place. In order to make quite sure that the improvement of the commutation at the lower speeds was due to a change in the available period of the coil, the machine was run with the poles not excited, and the armature current supplied from an external source. The records obtained exhibited the same characteristics as those in Fig. 11. This critical no-sparking speed of 640 revs. per min. was quite definite even to a few revolutions, and could readily be determined by gradually increasing the speed until sparks appeared. Although the available period increased as the speed was diminished, the magnitude of the commutation peaks was but slightly reduced, and in relation to the contact maker moved to the left, or if the position of the peak be considered as fixed, the contact maker moved to the right in the direction of time—*i.e.*, the extension of the available period occurred at the end of commutation, or in other words, the natural period remained nearly constant, and maintained the same relation to the commencement of commutation.

Influence of Commutating E.M.F. on Commutation.—The E.M.F. may be induced in the short-circuited coil by its movement either in a portion of the main magnetic field or in the field due to commutating poles. If the induced E.M.F. be constant or follow a known law the way in which the current varies may be expressed by the differential equation—$L\frac{di}{dt} = r_2 i_2 - r_1 i_1 + e_c$, where e_c = commutating E.M.F.

The E.M.F. should be sufficiently large during the early part of the short-circuit period to accelerate the commutation at the commencement. The effect of the acceleration in reducing the natural period and the maximum rate of change may be readily seen from Figs. 12 and 13. The various records in Fig. 12 were obtained by shifting the brushes forward by steps of one or more segments. The magnitude of the negative oscillation gradually diminishes and the peak moves to the left—that is, occurs earlier—as the brush lead is increased. At the same time the positive oscillation is considerably increased. When the lead is such that there is a relatively large E.M.F. induced in the short-circuited coil at the commencement of short-circuit a rush of current takes place at the first contact with the approaching segment, and the contact may be so heated that the continuity of contact

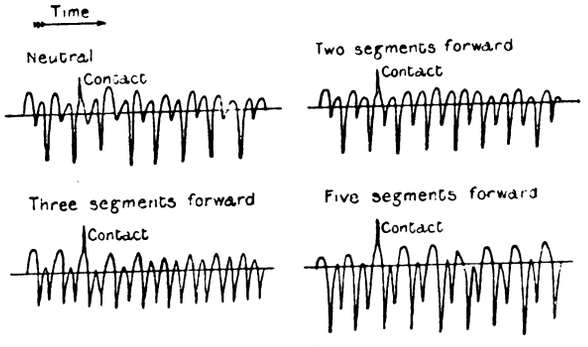

FIG. 12.

is broken and a spark occurs at the rear tip. If the E.M.F. be so large at the end of the commutation period as not merely to reduce the current flowing through the forward segment to zero, but to reverse its direction, a spark occurs at the forward tip. The common conception of an induced short-circuit current in the coil can only hold in the latter case above described; unless the current in one of the segments be actually reversed no current can flow across the brush surface, for the effect of the commutating E.M.F. when of normal magnitude is simply to increase the current in the rear segment and diminish it in the forward segment.

In the records given in Fig. 13 the commutating E.M.F. was induced by means of commutating poles. The width of each pole was 2¾ times the armature tooth-pitch. The commutating poles were separately excited and the field was varied from a minimum for no sparking to a maximum for no sparking. Such variation of the field

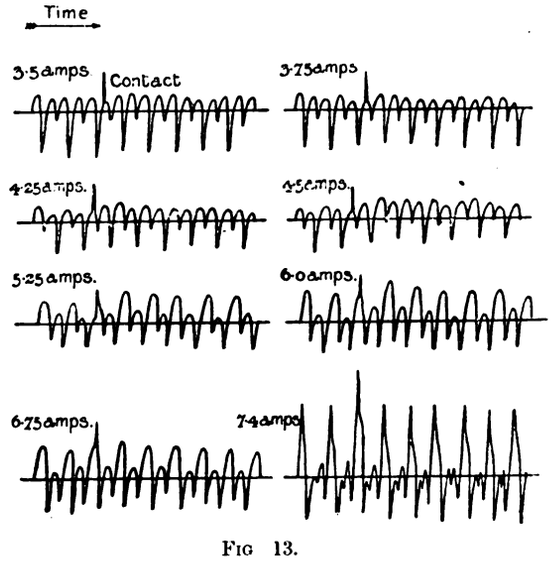

FIG 13.

produced effects similar to those obtained by shifting the brushes above described. The short-circuit current at the end of commutation is clearly shown by the large peak above the zero line. The presence of the commutating poles increases the self-induction of the coil, and therefore the natural period is increased; hence, if the natural period be correct without commutating poles it may be too long when commutating poles are fitted. In such a case a commutating E.M.F. is required to compensate the increased natural period.

The presence of the commutating pole, however, not only increases the self-induction of the short-circuited coil, but also increases the armature reaction flux in the commutating zone. This latter must be opposed by an equal flux from the commutating pole before any flux is available to generate the required commutating E.M.F. The two fluxes oppose but do not cancel one another in the commutating pole air-gap. The effect of such opposition is to spread out the fluxes in much the same way as the flux of two permanent magnets with similar poles presented to each other.

The surface of the commutating poles remains constant, but that of the armature varies as the teeth move past the pole face. Such variation gives rise to a corresponding change in the magnitude of the armature flux opposed by the commutating pole flux; thus when the commutating pole flux is equal to the minimum value of the armature flux, the periodic increase of the latter enters the commutating pole-face and induces an E.M.F. in a coil wound round the commutating pole shoe. As the pole flux is increased this magnetic oscillation is diminished, and the excess of the commutating pole flux over the armature reaction flux enters the armature and generates a commutating E.M.F. This latter flux is also subject to an oscillation owing to the movement of the teeth, which induces an E.M.F. in the search coil above referred to. The armature reaction oscillation, however, although diminished in magnitude continues to exist, for whatever be the magnitude of the commutating pole flux the two opposing fluxes remain independent of each other. The two oscillations, being produced by opposing fluxes, are approximately 180 deg. out of phase with each other.

Thus the resultant oscillation exhibited by coil 9 P on the commutating pole shoe forms a convenient method of studying the nature of the field in the commutating pole air-gap. In Fig. 14 are given the oscillations recorded corresponding to various commutating pole currents between the two extreme sparking limits. On record A the main oscillation is due to the armature reaction flux, the slight indent in the oscillation indicates that the commutating pole flux is greater

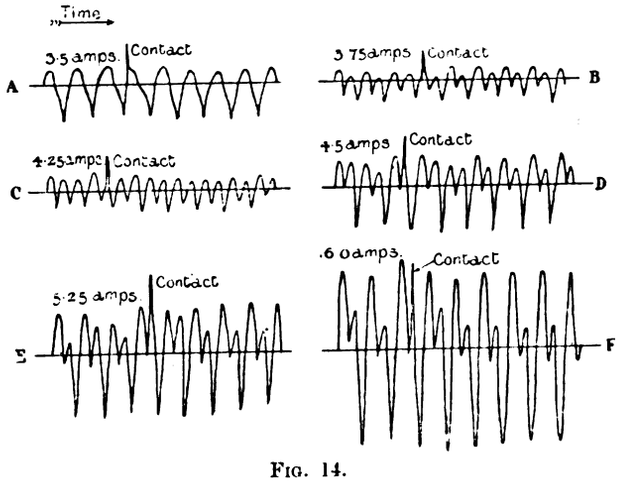

FIG. 14.

than the armature flux. The indent grows and in record B is about one-half the magnitude of the main oscillation, while in record C the original indent is larger than the original main oscillation. This may be seen by the position of the contact maker relative to the two oscillations. As the commutating pole current is increased, the oscillation of the commutating pole flux rapidly grows until in record F the original indent becomes the main oscillation, and the original oscillation almost an indent.

These records were taken at the same time as those given in Fig. 13, and hence each record given in Fig. 14 shows the condition of the field in the commutating pole air-gap, while the corresponding record in Fig. 13 shows the nature of the commutation obtained. A comparison of the two sets of records shows that for no sparking a slight commutation E.M.F. was required, but that there was a large range before the maximum permissible E.M.F. was reached. That the oscillations were not due to interference on the part of the other commutating pole was shown by the fact that a similar series of results was obtained when the other commutating pole was removed. In this case the minimum value of the commutating pole current for no sparking was but slightly greater than when two poles were fitted, but the maximum value was double.

This clearly shows that the commutating pole flux fulfils two functions: firstly, to oppose the armature reaction flux in the commutating zone; and secondly, to provide a commutating E.M.F. The first acts as pole against pole, the armature flux is not cancelled but only opposed. Each commutating pole deals with the pole-strength of the armature on its own side, and is not influenced by the presence or absence of the other pole. The commutating E.M.F., however, must be of approximately the same magnitude whether there be two poles or only one, and hence if the E.M.F. be generated in one side

Digitized by Google

only of the short-circuited coil the flux generating it must be doubled. Hence, when the commutating flux is small compared with the opposing flux, the ampere-turns required per pole are only slightly greater when only one pole is used than when two are in use, while when the commutating flux is large compared with the opposing flux, the ampere-turns required are practically double. Hence the use of one pole may effect a considerable saving in copper, and the range of commutation is greatly increased.

Width of the Commutating Pole.—Fig. 15 shows the E.M.F. curve recorded in coil 2 A wrapped round the middle of an armature tooth. A is the curve recorded when the width of the commutating pole is 2¾ times the armature tooth-pitch. The two extreme peaks, P and Q, in the commutating zone are due to the flashing of the flux across the slot, one as the coil enters under the commutating pole, and the other as it leaves. Between these two peaks two others, R and S, occur due to the commutation pulsation. The one to the left occurs in the tooth when to the rear of the slot being commutated, and to the other when it is in front. The four peaks are alternately above and below the zero line, and are of the same order of magnitude. The position of the inner peaks is fixed by the commutation conditions, but the distance apart of the outer peaks may be varied by varying the width of the commutating poles. If the width were so adjusted that the two outer peaks were superposed on the inner ones the four peaks might be made practically to disappear. In order to ascertain if this were possible narrow commutating poles were fitted, equal to 1¾ times the tooth-pitch, and the position of the brushes slightly adjusted so that the two left-hand peaks were superposed. The magnitude of the commutating pole current was also slightly reduced, and record B in the same figure was also obtained. If the oscillation in the tooth be neutralised the losses will be reduced and the efficiency of the machine increased. In the experiment only one commutation oscillation was neutralised, but if the width of the pole had been further reduced the other oscillation could have been neutralised

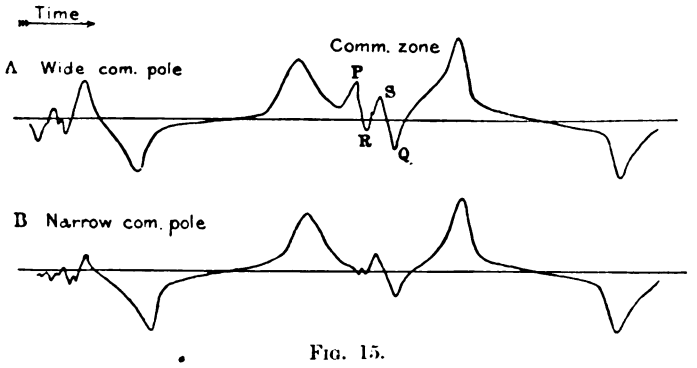

Fig. 15.

in the same manner. The velocity of the coil side relative to the flux is greater during the flash than when the slot is under the pole-face, hence the flux required would be less, and the ampere-turns could be reduced.

Cause of the Difference in Behaviour of the Positive and the Negative Brushes.—No law appears to hold which could be applied to all conditions of running, and to all brush materials, but the general observed result is that the negative brush is much more sensitive than the positive to change in temperature, current density, &c. Two observations in this direction were repeatedly made in this research—viz., that the warm brush vibrated very considerably when negative—but the same brush ran quite smoothly when positive, and that the surface of the negative brush was very much more highly polished than that of the positive. The vibration was entirely prevented by laying about six thicknesses of copper foil, each 0·035 mm. thick, on the forward tip, and a strip of copper on the rear tip, the metal being held in close contact with the brush by means of a copper clip; the metal was insulated from the carbon by very thin strips of mica. Both brushes were fitted in this way for the sake of uniformity.

The reason was thought to be as follows: The heat generated at the brush contact surface caused that surface to expand slightly, and the forward tip, being shielded from all draughts by virtue of its position, was subject to the greatest expansion, and actually lifted from off the commutator. The lifting was not continuous, but periodic; as a cold segment came under the tip, the latter came into contact with the commutator, but when the segment was heated by the current the tip was lifted off again. Thus a high-frequency vibration was set up which was communicated to the whole brush. The heat generated at the tip was not readily conducted away by the carbon, but the superior conductivity of the copper strips carried the heat away, and the large surface of the clip served to radiate it. The polished surface of the negative brush was due to its high temperature. This theory was fully substantiated by the following experiments:—(1) A brush polished up and in use for some time without the metal cooler was observed to have a band of brown nearly half the width of the brush on the forward part of the contact surface; slight sparking also took place. The metal cooler was then fitted, and after about two hours' running, the band of brown was found to be entirely rubbed away, while a new band appeared down the middle of the brush. No sparks were visible at the tip, but at the side of the brush about the middle an occasional spark appeared. The brush vibrated very considerably without the cooler, but with the cooler it ran quite smoothly, and the running was observed to improve as time went on. (2) With a very weak commutating pole field the current commutated very irregularly even with the cooler used in experiment (1), and a brown band 3½ mm. wide formed on the forward tip of the contact surface. When the field was strengthened regular commutation was obtained, and the brown band was rubbed away. (3) The commutating field was weakened as in experiment (2) and the brown band again obtained. The thickness of metal on the forward tip was then trebled, and regular commutation was obtained with the same commutating field, and the brown band was rubbed away. No sparking took place in either case when regular commutation was obtained.

From experiment (1) it is evident that with the cooler the brush was running on the two tips and the centre was not in proper contact with the commutator, and it may be concluded that without the cooler the forward tip was in bad contact with the commutator. It thus appeared that the surface of the brush expanded, but the cooler cooled the tips, thereby causing the curvature of the surface to be less and the tips to come into contact with the commutator. Experiment (2) shows the same effect; when the commutating field was weak the high inductance of the armature, owing to the presence of the commutator poles, caused the current to commutate very slowly, and consequently the forward portion of the brush surface carried a heavy current. This made the tip hotter than when there were no commutating poles, and hence the expansion took place, the bad contact at the tip caused the brown appearance and made the commutation irregular. When, however, the field was increased, the current density at the brush tip was reduced and the tip ran cooler. In experiment (3), when the tip was cooled by the extra metal, it was also kept in contact with the commutator and the brown band was polished off.

The observation that the negative brush was more highly polished than the positive may be considered in conjunction with another observation—*i.e.*, that the brushes after being freshly ground up would not take a good polish until current flowed through them. This was due to the warming effect of the current. Hence the degree of polish depends upon the temperature of the brush surface, and since the polish on the negative brush was better than that on the positive, it follows that the negative brush is hotter than the positive. The highly polished surface will make better contact, and hence the contact resistance of such a surface will be lower. Thus it is that the resistance of the negative brush is lower than that of the positive and the natural period is greater.

The difference in temperature between the two brushes is accentuated by the manner of commutation, but if the difference in temperature is the cause of the difference in commutation, the former phenomenon must be due to a cause entirely outside the phenomena of commutation. In order to ascertain this the following experiment was carried out: A carbon brush of the same material and shape as was used in the other experiments was placed on a thick piece of brass, and bedded down on to it by several thicknesses of copper foil. A slit was cut in the brass and foil, and a thermocouple was introduced into it so as to touch the carbon surface. The couple was composed of copper and constantan, separated from each other up to the joint by a thin strip of mica, and laid between two sheets of asbestos. The other element in the thermocouple was placed in a vessel of water in which a mercury thermometer was placed. The whole apparatus was carefully screened from draughts. Current was passed through the apparatus from carbon to copper, and also from copper to carbon. In the former case the carbon corresponded to a negative dynamo brush, and in the latter to a positive dynamo brush. Readings were taken for a series of currents in both directions (Fig. 16), and it will be seen that the difference in temperature is increased as the temperature rises.

The temperature of the actual commutator brush was also measured when the machine was running. The brush normally negative was fitted with a thermocouple on the forward tip as near to the contact surface as possible. The couple was in contact with the carbon and covered by a thick layer of asbestos, the whole being clipped on by a copper clip. The rise of temperature obtained when the brush was negative was 19·4°C.; the polarity was then reversed, and the

Digitized by Google

temperature gradually dropped until a rise of 15·2°C. was obtained. The temperatures measured are, of course, less than the actual temperatures of the contact surface owing the low heat conductivity of the carbon brush. The divided brush was afterwards put into position, and the temperature rise of the forward tip measured in the same way and found to be 14·8°C., which is slightly less than that obtained when the full surface brush was in position. This shows the possibility of reducing the temperature by improving the current distribution, although in doing so the actual area of the brush may be reduced. The explanation of this phenomenon lies somewhat outside the domain of electrical engineering, and the author had no opportunities of extending the experiments in this direction, but it is evident that this physical fact is the basis for the whole of the phenomena associated with the polarity of the brush. Evidence of the expansion of the brush contact surface was also observed by Mr. Lane in connection with some experiments on an alternating-current commutating motor, in which he also adopted the author's brush-holder and cooling device.

The importance of keeping the front tip of a brush cool cannot be over-estimated, for in it lies to a very great extent the secret of successful commutation. The overload capacity of a machine can be very greatly increased if the brush-tip be kept cool. The metal case in which the brush is usually fitted is not sufficient unless the case almost touches the commutator, and is in very good contact with the carbon. Since carbon is a very bad heat conductor, any artificial method of cooling must necessarily be deficient, and the best way to avoid a hot tip is to increase the rate of commutation during the early stages of short circuit. This can be effected by the proper distribution of resistance as already shown, or by a commutating E.M.F. The former method, however, has the advantage of greatly increased stability of the brush. When the tip lifts to any considerable extent,

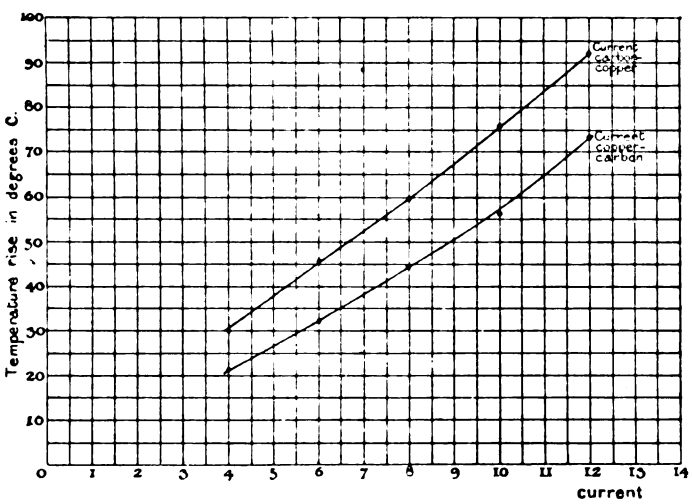

Fig. 16.

as was the case when no cooler was employed, the brush is exceedingly unstable and vibrates considerably. If the brush be high as in an ordinary plunger-holder, or attached to a rigid arm, as in a finger-holder, the vibration may be considerably multiplied.

Magnetic Oscillations Occurring in the Machine Parts.

Magnetic Oscillations in the Main Poles.—The shape of the E.M.F. waves recorded in coils 1 P to 4 P on the pole-tips was not found to vary with varying conditions of running, and hence the oscillations may be assumed to be entirely due to the teeth. Table I. gives the values of the oscillating flux expressed as a percentage of the maximum flux entering the coil. The load increases the magnitude of the oscillations, especially in the trailing tips. The presence of the commutating poles increases the oscillations in coils 2 and 3, but has practically no effect on those occurring in coils 1 and 4. This is probably due to the flux from the commutating poles. The "back pressure" of the commutating pole flux deflects the armature reaction flux more into the trailing tip of the main pole, while the commutating pole flux is in turn deflected into the leading tip. The extreme tips being already saturated are not influenced by this action. The coils 6 P, 7 P, and 8 P, each of 60 turns, showed but very slight oscillations on open circuit. This shows that only the flux generated by the outer layers near the pole-shoe is influenced by the teeth, and this flux crosses to the armature by way of the pole-tips. On load the oscillations in these coils were considerably increased

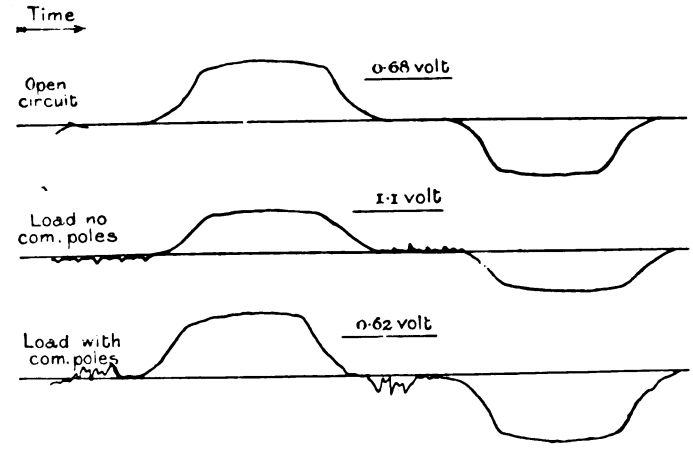

Fig. 17.—Coil 1A.

by the presence of the commutation oscillations. Coil 7 P, however, showed a greater increase than coil 6 P. This was due to the path taken by the oscillations—*i.e.*, through the tips and the outer layers of the exciting coil and then back through air, the major portion thus avoiding the solid limbs and yoke. It will be remembered that the coil 6 P was directly on the iron, while coil 7 P was over the exciting coil (Fig. 1).

Table II. gives the values of the oscillating flux in coil 5 P under various conditions expressed as a percentage of the flux when the machine is stationary. The flux in coil 5 P, when the machine was stationary, was measured ballistically and found to be $2{\cdot}68 \times 10^6$ lines. The flux oscillation is considerably increased by load, and is practically uninfluenced by the presence of commutating poles. This

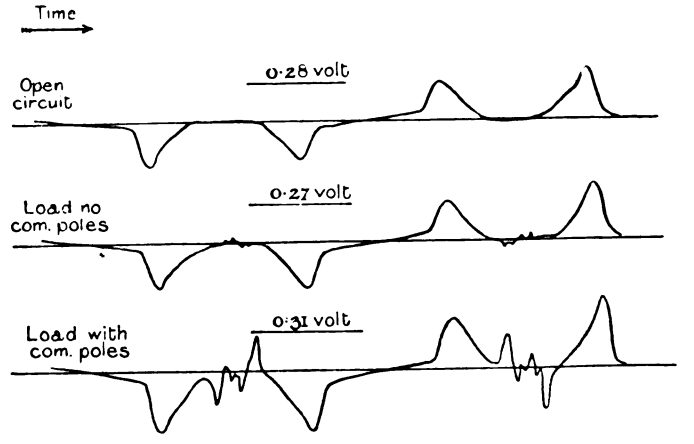

Fig. 18.—Coil 3A.

shows that although the magnitude of the peak is considerably reduced by the commutating poles, the actual value of the flux change is unaltered. This is due to the fact that whatever be the nature of commutation, the total current change remains unaltered.

Magnetic Oscillations in the Armature.—The E.M.F. waves recorded in the four coils on the armature under various conditions of running are given in the Paper. Figs. 17 and 18 herewith show the waves for coils 1 A and 3 A, whilst Fig. 19 shows to a larger scale the part of the wave generated in the commutating zone. The commutation oscillations are very marked, and the difference in magnitude between alternate peaks due to the positive and negative brushes respectively is clearly seen. No oscillations were induced in any of the search coils in the commutating zone on open circuit.

Digitized by Google

The E.M.F. peaks induced in coil 1 A gradually increase as it approaches the commutating zone, and diminish again as it leaves it. When the coil is actually in the commutating zone, it links one-half the total flux induced by the current in the short-circuited coil, except that portion that crosses the slot below the tip; the E.M.F. peak at this instant is therefore nearly equal to the self-induction or "reactance" E.M.F. per conductor of the short-circuited coil, while the other peaks give the magnitude of the E.M.F.s induced in the adjacent coils. The records for the coils 2 A and 3 A consist of four principal peaks, two successive ones in one direction and two in the opposite direction. The first two are produced by the commutation of the top and bottom coils in the slot ahead of the tooth by the positive and negative brushes respectively, and the second two are due to the commutation of the coils in the slot immediately to the rear of the tooth. Here again the difference in magnitude between the oscillations due to the positive and negative brushes will be noticed. The remaining peaks are due to the stray flux from the short-circuited coils entering the neighbouring teeth.

Results and Conclusions.

(1) The natural period of the short-circuited coil may be varied by varying its contact resistance, or by properly disposing the resistance over the brush surface. (2) Sparking depends upon the relation of the natural period to the available period. (3) The maximum rate of change of the current during commutation may be reduced by reducing the natural period, and at the same time the overload capacity of the machine as regards sparking will be improved. (4) The maximum rate of change may also be reduced by accelerating the commutation during the early portion of the short-circuit period by means of a commutating E.M.F., and this has the same effect as reducing the natural period of the coil. (5) The ampere-turns necessary on the commutating poles may be reduced if the flash across the slot be used to generate the commutating E.M.F.

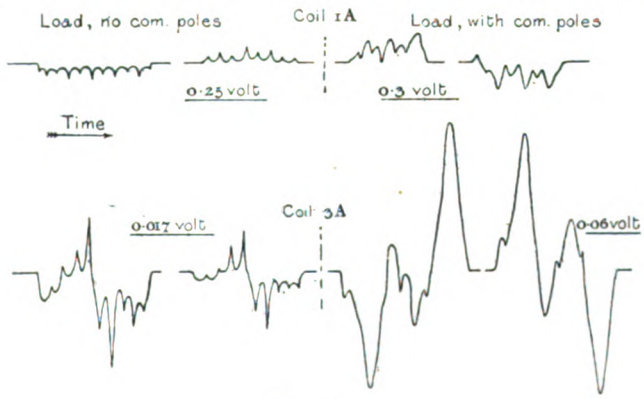

Fig. 19.

The E.M.F. generated in such a manner possesses approximately the correct wave shape, and the magnetic oscillations in the armature teeth during commutation are thereby reduced. (6) If only one commutating pole be fitted, the ampere-turns necessary are less than when two are in use. (7) The commutating pole flux fulfils two functions: (1) to generate the commutating E.M.F., and (2) to oppose or press back the armature reaction flux. (8) The negative brush is hotter than the positive; the higher temperature causes the negative to take a higher polish than the positive, thereby reducing its contact resistance. The lower contact resistance increases the natural period, and renders the negative brush more liable to sparking than the positive. (9) The higher temperature of the negative brush causes it to expand more than the positive. The forward tip is generally the hottest part of the brush surface, because it is shielded from draughts. The forward tip is alternately heated and cooled as the segments pass under it, and vibrates with the frequency of the segments. This vibration renders the brush unstable, and the commutation irregular. (10) The forward tip may be cooled, the vibration avoided, the commutation made regular, and the sparking limit raised by a piece of metal in good contact with the brush at the forward tip and provided with a relatively large radiating surface. (11) The results in (10) may also be obtained by preventing the rush of current at the end of commutation, either by reducing the natural period of the coil or by accelerating the commutation during the early stages by means of a commutating E.M.F. (12) The vibration of the forward tip of the brush causes a minute arc to be periodically set up between the carbon and the commutator, which causes a brown band to form on the brush and a deposit on the commutator.

This research was carried out at the Technische Hochschule at Karlsruhe, Baden.

REQUIREMENTS FOR AN INDUCTION MOTOR FROM THE USER'S POINT OF VIEW.*

BY W. B. NYE.

The author discusses this problem not as an engineer, but from the point of view of that large class which pays the bills, and to which the motor is but a means to an end. The prime requisite from a manufacturer's point of view is continuity of operation. To secure continuity of operation and ease of repair, former-wound impregnated coils should be used. Impregnation of coils is suggested because in many industries motors are subjected to moisture, steam, fumes, either acid or alkaline; dust, which may be organic, and which by its decomposition affects the insulation. Impregnation renders the coils much more immune to these conditions.

However good the motor may be, sooner or later repairs will be necessary, and in that case a former-wound coil is much more easily put in place than any other type. Coils should be made accurately to size, so there may be no difficulty in placing them in the slots, and there should be good mechanical connection between coils, as lack of this often leads to open-circuiting. It is also desirable to have a good terminal board, and preferably flat, flexible copper leads, so as to do away with soldered or screwed terminal connections. It would also be well to use particular care in the quality of the insulation on the copper bars in the rotor where they pass through the slots, as this would reduce the amount of labour in repairs. It is to be hoped that some better scheme may be devised for connecting the conductors to the outside rings, as bolts corrode, and it is seldom possible to remove them without twisting them off, which again occasions delay.

Bearings should be long, well designed, and filled with the best quality of babbitt. Great care should be given in designing the channels for the oil-rings to travel in, so there may be no chance for the ring to catch; and the sight-feed or overflow pipe should be piped away from the bearings, so that inspection may be given it regularly.

Shafts should be stiff, and the motor so designed as to permit of considerable overhang of the driving pulley. There is a tendency on the part of designers to increase the diameter of the driving pulley, narrowing the face in order to reduce the overhang; but at the speed at which most motors run, these large driving pulleys occasion difficulty in getting down to such speeds as are common in mill practice. In fact, the motors which so far have come under my notice have practically all had to be equipped with smaller, wider pulleys than those sent with them. This condition might as well be realised, and the motor designed for this service.

My experience has been mainly with a group drive, hence there is a chance of continual slow growth in the power requirements, and for that reason the motor should be capable of standing up to the load, even if in excess of its name-plate rating. A motor, therefore, should be designed to stand at least 25 per cent. continuous overload without undue heating, and should be so designed as to permit of good ventilation and a ready access of the air jet in cleaning out.

Controllers, and particularly switches, should be of the oil-immersed type, doing away with fuses, thus meeting the requirements both as to fire hazard and to life, from contact with the average open-jaw switch. Experience shows that auto-transformers for use in connection with induction motors have almost invariably been too small, and after considerable trouble in endeavouring to start the motor, it has been necessary to secure larger ones. Designers may well consider this point and be more generous in their provision of capacity in these most necessary appurtenances. The user can well afford to pay a little more for a well designed motor containing some reserve in capacity and ability to stand hard usage.

In the business in which I am interested (paper manufacturing), we have not thought it wise to take up the application of the individual motor to the individual machine, although this has been developed quite fully by electrical engineers. We have so far made use of group-drives, so arranging the groups as to make use of but a few standard sizes, of which we always keep one or two in reserve for use in case of emergency. The standard group might be said to be that driven by a 100 H.P. motor, of which we have twenty, and for which we constantly hold two extra motors in reserve, one of them on trucks ready to be hurried to any point required. In this way, should anything occur to a motor, it can be removed, and a new one slipped in its place, with the loss of but a few moments, and the repairs made in the shop at leisure. This same practice holds good for all sizes up to 150 H.P., above which this scheme is not practicable.

* Abstract of a Paper read at a joint meeting of the American Institute of Electrical Engineers and the American Society of Mechanical Engineers.

The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom .	26s. 0d.	13s. 6d.	7s. 0d.	Post free.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New Volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. B Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-ninth issue of the Supplement will be published (Gratis) with the number of "THE ELECTRICIAN" for May 27.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

ELECTRICITY IN MINES.

HERBERT SPENCER was never tired of pointing out that the interference of the State with the liberty of the subject was increasing and ought to be diminished, and that the happiness of the human race was likely to be inversely proportional to the number of Government inspectors. Nobody nowadays believes in all this: on the contrary, there seems to be a well-rooted belief that without the help of the authorities it is almost impossible for us to tell what is for our good. Consequently, we accept from time to time, as meekly as is possible, such codes of rules as are inflicted on us from above, though they often run to such length that much careful study is needed for their interpretation. The infinite multiplication of wiring rules is a case in point, and a nuisance that might well be abated, even to the irreducible minimum, by the adoption of the Rules of the Institution of Electrical Engineers

It seems now that the Home Office is of opinon that the Regulations relating to the Use of Electricity in Mines require revision; either they do too little and are defective, or they do too much and need modification. Or more probably still, they do the wrong thing, and need correction. Such is the result of the interference of the State. It will be admitted that the use of electricity in mining work has been attended with very hopeful results. There is no sphere of work falling under the head of the engineering aspects of electricity which has of late years met with a more encouraging expansion. As to the class of plant that has been put in, this varies, no doubt, from good to bad. Certainly no sort of finality has been reached. There is, and will long remain, much that is debatable as to methods and appliances; but a premature codification or too rigid application of general principles might prove very undesirable. Evolution has played its very important part; in

Digitized by Google

other words, experimental errors have been corrected gradually, and much that seemed at first likely to be suitable to the needs of the case has been replaced by something else that has been shown by experience to be better. The type of cable has sometimes led to failure, and the lead-covered cable seems to be falling into disrepute in this underground work. Armoured cables, carefully chosen, are preferred. Such points are, doubtless, of the greatest importance; but they are precisely the sort of thing which cannot be dealt with under any kind of regulation imposed from above. The aim and object of all engineering work is to approach as nearly to the ideal as is humanly possible, and never, if only from business motives, to be in favour of petty economies. This can only be done if a fairly free hand is given to those to whom the responsibility is entrusted of carrying out the work, and they stand to lose or gain in the long run in proportion to their success or failure.

The aim of the Home Office is, doubtless, to secure immunity from the two sources of disaster which may be classified under the heads of shock and explosion. Safety from shock is supposed to result from establishing satisfactory "earths"; how and where this is to be done is the problem, and there is, of course, at the moment no one recognised method that is practised to the exclusion of all the others. Sometimes the cables are earthed at the top of the shaft; or, again, in the sump at the bottom; or, again to the rails forming the track. All of these plans require discretion and experience. The rails may be resting on an insulating layer of subsoil, in which case the "earth" formed by such rails may be actually a source of danger; and in case of any discontinuity in the armouring of the cables danger may arise in another way. Experience is a far more useful ally than any number of regulations, and the short time during which colliery work has had the advantage of electrical auxiliaries has already taught us much. The human element, too, is by no means negligible, and of the 1 per cent. of the total fatalities which is attributable to electricity a large proportion have been of such a nature that they could hardly have been avoided by any preventive system, short of the useful one by which we are content to learn most things. As has been well said, the school of experience is the best one, but it is a pity the fees are so high. In the early days of telegraphy large numbers of birds used to kill themselves by flying against the wires. Now they seem to have learned better; and every living thing learns in the same way—man himself included. Complaints are often made that it is not easy to find men who have had much experience in the every-day work of a colliery installation, and that in consequence it is necessary to engage men who have yet to learn some of the elements of such work. This is probably true enough, but though there may at the moment be a shortage in the supply of such men this is not likely to be the case for long. Such troubles, therefore, as are traceable to this cause are certain to pass away.

The second point at which the regulations would be likely to aim would be the provision of means for lessening the risk of explosion. This is notoriously a very difficult and obscure problem. Methods that are suitable in one pit are quite insufficient in another. Some pits are so fiery that it may at present seem well to leave them almost out of account, as the most perfect devices might well fail, even if installed with the utmost care. Local conditions are in these cases all important, and any general conditions intended to cover such cases would only err on the side of excessive rigidity. The precise mechanism by which explosions are caused is not altogether as certain as is sometimes supposed, and the parts played by coal dust, moisture, and inflammable gas are not at all clear. The one and only remedy that has been suggested has been to enclose everything. This is a move in the right direction, if a certain amount of latitude is allowed for the interpretation of the conditions of the special case. It is often the method of enclosing the switch or motor that is more important than the mere fact of enclosing it; the case of Davy's safety lamp is a classical instance of this.

We make no claim, of course, that we should be allowed to go on our way without let or hindrance. It is too late in the day for such a plea to be of any avail, even if it were desirable. But we do urge that as free a hand as possible should be given to those who are in a position to avail themselves of the benefit of their experience. Anything that can be done towards placing the responsibility definitely on the right shoulders we should heartily welcome; but a sub-division of such responsibility among a variety of officials, no one of whom is clearly in intimate contact with the work, or has sufficient technical knowledge to understand the problems involved, is clearly to be deprecated. If the authorities work with such points in view it is needless to say they will have our entire approval.

OBITUARY.

MAJOR P. CARDEW, R.E.

We sincerely regret to record that Major Philip Cardew died at about noon on Tuesday last. He underwent a serious operation in November last for a tumour behind the nose, and never really recovered from its effects. He has, in fact, been sinking since that time.

Philip Cardew was born on September 24, 1851, and passed out with honours from the Royal Military Academy, Woolwich, in 1871, being awarded the Pollock gold medal as the most distinguished cadet of his year.

He was placed in charge of the military telegraphs at Bermuda in 1876, and in 1877 he joined the Submarine Mining Service, being a year later appointed assistant instructor, and in 1883 instructor, in electricity at Chatham. In 1888 Major Cardew was appointed electrical adviser to the Board of Trade, which post he held until 1899, when he resigned in order to take up consulting work in partnership with Sir W. H. Preece, K.C.B., and his sons, thus forming the well-known firm of Preece & Cardew. The firm were consulting engineers for many electricity supply and tramway undertakings, and, in connection with this consulting practice, Major Cardew made a journey on behalf of his firm to Sydney (N.S.W.) to report upon the municipal electricity undertaking. He was also engaged in many important arbitrations. During Major Cardew's tenure of office at the Board of Trade the development of electricity supply for lighting, tractive power, and other purposes was developed, and regulations and numerous other important questions settled. It was during that period that the rules for

Digitized by Google

safeguarding underground pipes from electrolysis by stray currents from electric traction systems, and which have proved so beneficial, were drawn up.

Major Cardew was a director of the London, Brighton and South Coast Railway, which has lately had the distinction of being the first to adopt the single-phase electric system for the working of its suburban lines. He was the author of many inventions and improvements, among the more important of these being :—A system of vibration telegraphy, which has been extensively used for field telegraphs since 1881, as it enables communication to be maintained through a very defective line ;

MAJOR P. CARDEW, R.E.

a voltmeter, working by the heating of a fine wire in a compensating tube ; a safety device for transformers ; and a system of regulating the fall of potential in the return circuit of electric tramways and railways. Major Cardew was the author of numerous Papers, among which may be mentioned one on "The Application of Dynamo-electric Machines to Railway Rolling Stock," published in March, 1881 ; and one on "Electric Railways," read before the Society of Arts in March, 1901.

SIR WILLIAM HUGGINS, K.C.B.

We regret to record the death, on Thursday, May 12th, of Sir William Huggins, K.C.B., F.R.S. The deceased was 86 years of age. Though by no means intimately connected with electrical work, Sir William Huggins is deserving of honour by all scientists on moral grounds alone, for he was one of those who without being forced by the spur of obligation followed science for its own sake alone. In his observatory which he erected at Tulse Hill in 1856 he carried on, in conjunction with Lady Huggins, his work on astronomical spectroscopy, a field of research which had been made possible by the discovery by Kirchoff of the true significance of the Fraunhofer lines. A full consideration of Huggins' work is not within the scope of THE ELECTRICIAN, but we may mention that besides scientific, he also received, though somewhat tardily, official recognition. He was made K.C.B. in 1897, and a member of the Order of Merit on its foundation. He had been elected a Fellow of the Royal Society in 1865, and received from them the Royal Medal in 1866, the Rumford Medal in 1880, and the Copley Medal in 1898. He succeeded Lord Lister, as president of the Society, in 1900. He was also an honoured member of many foreign learned societies.

THE ELECTRICAL EQUIPMENT OF SMITH'S DOCKS, MIDDLESBROUGH.

The electrical equipment of the shipyard and graving docks of Messrs. Smith's Docks Co., Middlesbrough, presents many features of interest. About 18 months ago the Company, acting on the advice of its consulting engineer, Mr. J. Mitchell Moncrieff, decided to re-claim a portion of the foreshore of the River Tees covering some 16 acres of ground near Middlesbrough. The choice of the site was determined by a scarcity of dry docks on the Tees capable of dealing with the largest ships calling at Middlesbrough and by a plentiful

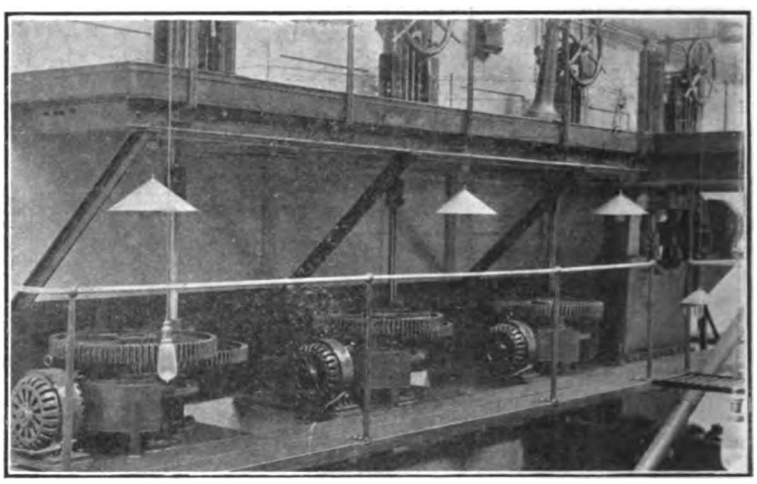

FIG. 1.—VALVE CONTROLLING GEAR.

supply of engineering material and labour. The work was carried out by Messrs. John Aird & Co., and includes a shipyard with offices, fitting, machining, wood-working and blacksmithing shops and two dry docks, one 550 ft. long and 67 ft. wide, and the other 450 ft. long and 61 ft. wide, both being 26 ft. deep at high-water mark of ordinary spring tides.

Full advantage has been taken of the economy and convenience resulting from the electric drive, all the machinery employed being

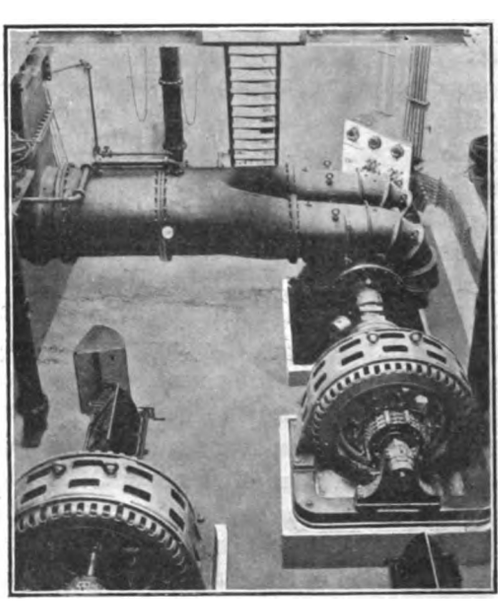

FIG. 2.—VIEW OF UNDERGROUND PUMP ROOM.

operated, and all the lighting effected, by this means. The dock is provided with a large travelling jib crane, built by George Russel & Co. This crane has a capacity of 25 tons at 42 ft. radius, 15 tons at 70 ft. radius and 10 tons at 90 ft. radius. It is fitted with an auxiliary hoisting gear for lifting loads up to 5 tons at a rate of 100 ft. per minute. The lifting speed with a 25 ton load is 20 ft. per minute, and for the lighter loads is proportionately greater. The crane is equipped with four Westinghouse motors of 48, 20, 20 and 15 H.P. for hoisting, derricking, slewing and travelling respectively,

Digitized by Google

which, with the exception of the travelling motor, are mounted in a cabin on the rotating frame, the travelling motor being mounted on the crane carriage and controlled from the cabin on the rotating frame at such a height as to command a good view. Each of the motors is fitted with an electromagnetic brake, and the hoisting and derricking gears are also equipped with an automatic, mechanical and foot or hand brakes. The crane receives its power from a number of plug boxes placed along the track through a flexible armour-covered cable.

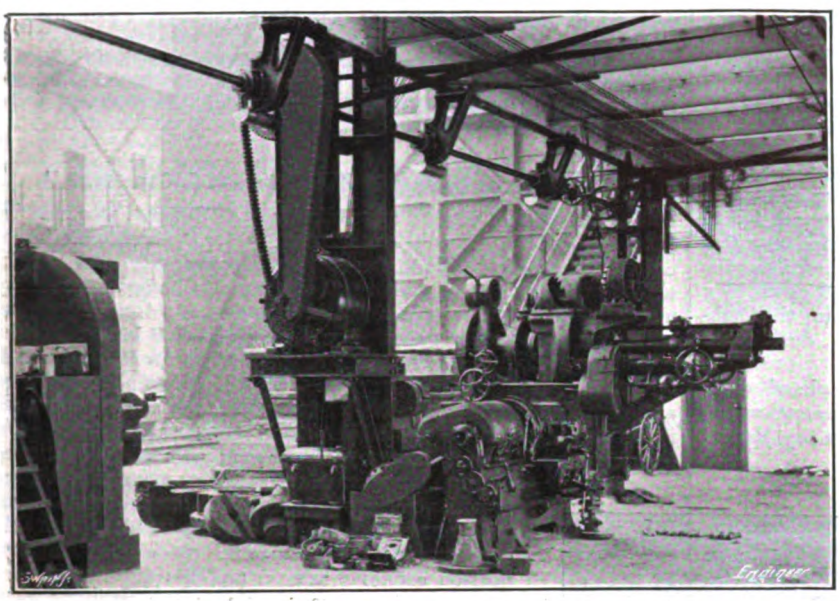

FIG. 3.—SHAFT DRIVEN BY MOTOR AND CHAIN.

Near the entrance to the docks is an underground pump room, which contains the pumping plant, consisting of two main twin Worthington pumps with 48 in. diameter suction and delivery pipes connected direct by flexible couplings to two 400 H.P. Westinghouse slip-ring motors operated by liquid starters. A view of these pumping sets is given in Fig. 2. There is also a 12 in. Worthington low lift pump used for draining purposes. The pump has a capacity of 2,000 gallons per minute against a maximum head of 45 ft. when running at 760 revs. per min., direct connected to a 35 H.P. Westinghouse squirrel-cage motor. A small priming pump is driven through a chain drive by a 4 H.P. motor. An appliance of this kind is necessary in such an installation in order to re-charge the pumps should they happen to lose their water through the emptying of the dock.

The main pumps are designed for a constant output of 42,000 gallons per minute at a speed of 295 revs. per min., but an official test shows that this figure was exceeded by 10 per cent., the docks being emptied in a correspondingly shorter time. On this test, the maximum pump efficiency is given as being 84 per cent., and the load on the motor at this point was only increased by 16 per cent. when working at the lowest head.

The gears for the emptying and discharging valves can be operated either electrically or by hand. A portion of these gears is shown in Fig. 1, the gears being driven by eight 4 H.P. motors, each provided with automatic cut-out gear to prevent any possibility of the valves jamming. The switchboard controlling the various motors receives a 440 volt three-phase supply direct from the sub-station, and consists of five polished white Sicilian marble panels, on which are mounted the necessary switches, fuses and both indicating and integrating instruments. A telegraph gear is provided for the convenience of the docks master in controlling the operation of the pumps. The capstan equipment of the docks consists of five capstans, each with a haulage capacity of 5 tons at a speed of 40 ft. per minute and 1¼ tons at a speed of 120 ft. per minute. The capstans are operated by three-phase motors, three being placed at the entrances to the docks and one at the end of each dock.

The shipyard, which is on the Middlesbrough side of the dry docks, is capable of accommodating 18 large steam trawlers at one time. Near the yard is a gut for berthing ships, while their machinery is under repair, and immediately in the rear of the yard is a machinery shop 220 ft. long by 140 ft. broad, containing a mould, lathe and two furnaces, suitable for angle iron 48 ft. long and plates 25 ft. long heated by two gas producers manufactured by the Gas Power Co.

A fine set of rolls, 15 in. in diameter by 30 ft. long, made by James Bennie & Sons, has together with other machines, been removed to this machinery shop. The set is driven by a 75 H.P. Westinghouse slip-ring motor operated by a liquid controller for rolling, and 25 H.P. Westinghouse squirrel-cage motor for lifting the rolls. The joiners' and blacksmiths' shops, the former covering an area of 130 ft. by 70 ft. and the latter 111 ft. by 70 ft., will, when fully equipped, contain 30 fires, a large ground fire, a Roots blower driven by a 15 H.P. alternating-current motor, and a 5 cwt. Massey power hammer driven by a 20 H.P. alternating-current motor, which are at present in a temporary shed near the fitting and machine shops. All these machines are individually driven, and among them are a 30 ft. plate edge planing machine and a large roll 2 ft. diameter by 17½ ft. long, each driven by a 20 H.P. motor, while outside are a punch and shears 1½ in. by 1½ in., driven by a 20 H.P. motor mounted on the top of the machine. A ⅝ in. joggling machine, geared to a 40 H.P. motor, a plate straightener with rolls 5½ ft. long, driven by a 50 H.P. motor, and a horizontal bending machine, driven by a 20 H.P. motor mounted on the machine, all the motors, both here and in the temporary shed, being protected by wooden casings.

In the machinery shop it is interesting to note the method of driving the two lines of shafting, which run practically the whole length of the building. Each line is driven by two 30 H.P. motors through short lengths of chain drives; one is illustrated in Fig. 3 with half the gear case removed; but by disconnecting the coupling joining the two halves of the line shaft each half can be driven by one motor. There are also two large shafting lathes, each 30 ft. long, driven from the main shafting, a large horizontal machine driven by a 10 H.P. motor, and a medium-sized vertical boring machine driven by a 5-20 H.P. squirrel-cage motor, the speed variation being obtained by special motor winding connections. The vertical boring machine is illustrated in Fig. 4.

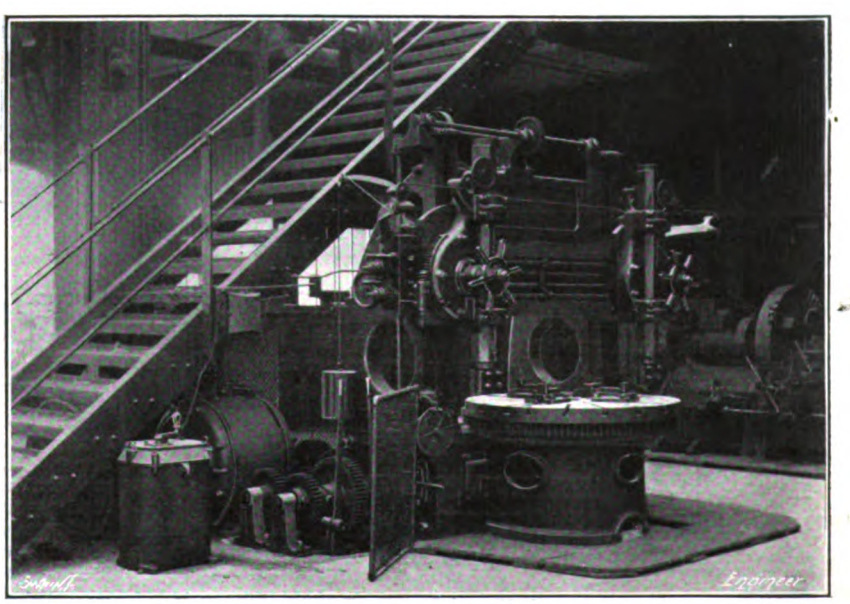

FIG. 4.—ELECTRICALLY-DRIVEN VERTICAL BORING MACHINE.

A sub-station in a corner of the shop contains two 60 kw. motor-generator sets supplying direct current for lighting the docks and works and two distributing switchboards, one with eight panels for alternating current controlling the air compressor motor, the cap-

Digitized by Google

stans, fitting shop and the motors of the motor-generator sets; the other five panel direct-current board controlling the generators and lighting circuits.

The main alternating-current panel contains an automatic oil switch and an ammeter and voltmeter, whilst each of the other alternating-current panels contains an oil switch, ammeter and an integrating wattmeter, and each of the direct-current panels a two-pole switch, porcelain-handle fuses and ammeter, whilst the generator panels also are provided with voltmeters and voltmeter plugs. All circuits which lead from the station to the outside circuits are protected with choking coils and lightning arresters, which will be noticed in Fig. 5. A 22 k.v.a. 440/220 volt single oil-insulated self-cooled transformer is installed in the station for supplying the lighting when the direct-current sets are not running, and also a compressor for furnishing air at 100 lb. pressure to the pneumatic tools. This machine, driven from a 120 H.P. slip-ring motor on the gallery above, is operated by an automatic liquid starter controlled by the variation of air pressure in the air receiver. Power is fed to this station at 440 volts from the main sub-station situated near this shop, at which three-phase power at 3,000 volts, received from the Cleveland & Durham Electric Supply Co., is transformed down by a 500 k.v.a. oil-insulated self-cooled transformer. From this sub-station circuits are also run direct to the pump house, dock crane and shipyard.

The whole of the electrical installation has been completed under the supervision of Mr. C. W. Fairweather, consulting electrical engineer to Smith's Docks Co., and the wiring carried out by Messrs. Warren, Beattie & Co., of Middlesbrough.

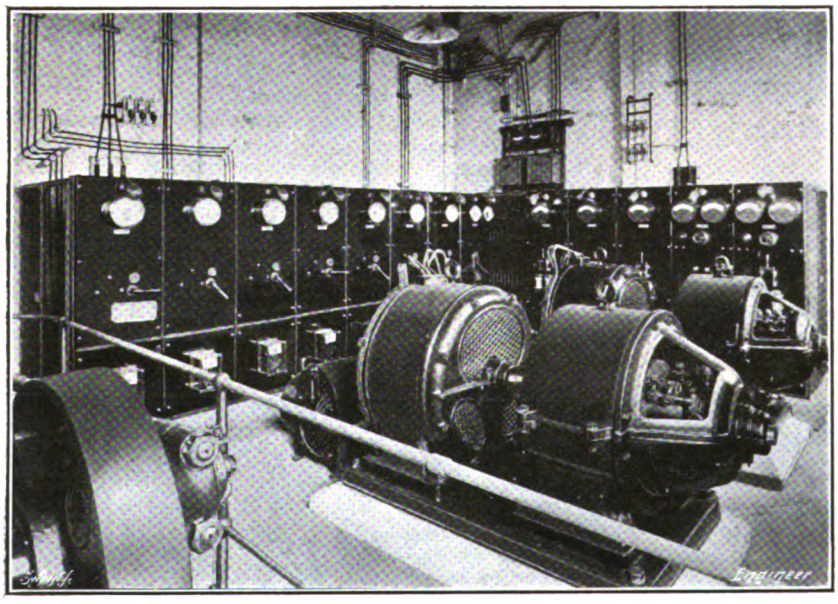

FIG. 5.—VIEW OF SUBSTATION.

With the exception of the capstans, the whole of the electrical apparatus for the above installation was supplied by the British Westinghouse Electric & Mfg. Co. to whom we are indebted for the particulars here given.

PHYSICAL SOCIETY.

At the meeting held on April 22nd, Prof. H. L. CALLENDAR, F.R.S., President, in the chair, Mr. W. A. SCOBLE read a Paper entitled

"Further Tests of Brittle Materials under Combined Stress."

A former Paper described tests on cast iron, which is the brittle material which is most commonly employed in engineering practice. The cast iron yielded somewhat, and it was necessary to assume a redistribution of stress before fracture. Then the maximum principal stress appeared to be the best criterion of strength. The tests described in the present Paper were made on hardened cast steel, which material was selected because it obeys Hooke's Law to fracture. The specimens were $\frac{3}{4}$ in. diameter and 30 in. effective length, and were tested under combined bending and torsion. As it was not possible to ensure that the hardened bars were of exactly equal strengths, a bar was first fractured under combined loading, then one portion was tested under bending alone, and the other part in simple torsion. Thus each bar afforded independent evidence on the law of failure. Neither the maximum shear stress nor the maximum strain was constant at fracture, but the results indicated that the maximum principal stress is the best criterion of strength for a brittle material under combined stress. In general, the hardening did not affect the strength of a bar to resist bending, but it doubled the torque which was required to cause failure.

Dr. RUSSELL asked the author for a definition of a brittle material.

Mr. R. S. WHIPPLE asked what were the advantages of hardening in vitriol.

Mr. SCOBLE, in reply, said a brittle material was one which did not yield before fracture, although cast iron, which was usually classed as brittle, yielded to a slight extent. Tool hardeners found that hardening in vitriol was preferable to hardening in oil.

A Paper on

"The Magnetic Balance of MM. Curie and C. Cheneveau,"

by C. CHENEVEAU, with an appendix by A. C. JOLLEY, was read by Mr. A. C. JOLLEY. This balance is intended for the determination of the coefficient of specific magnetisation, susceptibility and permeability of feebly paramagnetic and diamagnetic bodies. The body under investigation is suspended from one arm of a torsion balance, which measures the force exerted on the body when it is placed in the non-uniform field of a permanent magnet. The torsion balance is formed by a horizontal rod suspended by a long fine platinum wire and carrying at one end a hook from which the substance under investigation can be suspended in a small enclosing glass tube. On the other end of the torsion arm a copper sector is fixed which moves between the poles of an auxiliary magnet and thus provides efficient damping. A second branch arm is also provided, upon which may be placed suitable counterweights to balance the specimen. The suspension carries a mirror, and the movements are read on a translucent scale in the ordinary way. The magnetic field is that of a large circular permanent magnet mounted in such a way that the vertical gap may be made to describe a semicircle of radius equal to the length of the torsion arm, and the movements of this magnet are controlled by the observer at the screen by means of cords. An empty containing tube is first mounted on the balance, and the maximum deviation of both sides of the zero is obtained by bringing up the magnet towards each side of the specimen. The tube is now filled to a given mark with a known mass of pure distilled water and the variations observed as before. The water is now replaced by a known mass of the substance to be examined occupying the same volume or the same vertical height, and again the deviations are observed. The Paper indicates how the value of K may be calculated from these observations. Experiments have been performed with various metals and alloys, and the results are tabulated and discussed in the Paper.

Mr. A. CAMPBELL said that for certain experiments, and in the construction of certain instruments it was essential to know that the materials used were non-magnetic; and he thought the author's instrument would be useful. It was very difficult to obtain non-magnetic brass.

Mr. W. DUDDELL asked if the specimens used were specially cleaned, as the oxides and sulphides of many metals were magnetic. It would also be necessary to keep them clean to get trustworthy results.

Mr. D. OWEN expressed a doubt as to the accuracy of the results attainable by this apparatus used as described by the authors in the Paper. Theory required that the specimens of the standard substance and that under test should be exactly equal in size and shape, and similarly situated in the variable magnetic field when the observation of maximum force is taken. In many ways this condition might be departed from in the experiments described. The size of the test-tube used to hold the specimen was a considerable fraction of the interpolar space, and, excepting in the case of liquids, it would be difficult to ensure identity of form of the samples in the correlated pair of experiments. Absence of coincidence between the axis of rotation of the magnet and the axis of the torsion wire would cause an error of position varying with the deflection of the balance arm. Again, the magnetic pull parallel to the balance arm would cause movement of the specimen to an extent depending on its susceptibility and its density, though the effect was likely to be very small. These causes might account for the authors' observations of apparent dependence of K on the mass and length of specimen.

The authors were also asked whether they had any experimental data as to the independence of K with respect to temperature.

Dr. RUSSELL regretted that the author had not explained more fully how the magnetisation of the specimen under test was maintained uniform. Any lack of uniformity would seriously affect the accuracy of

Digitized by Google

the results. He thought that the great discrepancies found by Mr. Jolley in the apparent value of the coefficient of the specific magnetisation of copper for specimens of different lengths must be due to an uneven distribution of the magnetic field. When the specimens were very feebly magnetic he considered that it was legitimate to make the assumption that the intensity of the magnetisation was proportional to the field. He did not see, however, how the balance could be employed to test strongly magnetic substances. He suggested that the specific magnetisation of water might vary largely with temperature. It was interesting to find that the discrepancies between the calculated and the observed values of the inductance of a certain brass conductor had been traced to the magnetic qualities of the brass. In his opinion errors in the computed values of inductance standards, due to the permeability of the conducting material differing from unity by a very small fraction, would in general be negligible.

The SECRETARY read a letter from Dr. C. V. DRYSDALE in which he stated that Mr. Jolley's experiments with the magnetic balance proved its value, both scientifically and commercially, as a means of rapidly estimating the composition and purity of alloys and other materials. The instrument enabled the magnetic qualities of materials to be obtained as easily as the specific gravity measurements which are usually employed as an aid to practical analysis, and it formed a kind of magnetic hydrometer which gave the specific magnetisation instead of the density of the substance as compared with water. The displacement principle of Poisson and the derivation of the force as the slope of potential were both of great importance, and an apparatus such as the author's, which showed the practical application of these principles, was welcome.

Mr. C. W. S. CRAWLEY drew attention to the fact that if the brass rods were cut with steel shears they would be rendered magnetic. Brass tubes prepared by drawing through steel dies were generally magnetic. He asked if the variation of the value of K for copper was due to impurities.

Mr. R. S. WHIPPLE asked if the author had performed any experiments on wood or ebonite, and, if so, with what results.

Mr. JOLLEY, in reply, said he could fully endorse Mr. Campbell's remarks concerning the difficulty of obtaining non-magnetic brass which seemed to be quite rare. In reply to Mr. Duddell's point concerning the cleaning of the specimens, a fair amount of care was taken to keep the specimens clean; they were handled with ivory forceps, and in most cases they were bright new samples of rod and wire, which to the eye certainly did not seem in any way oxidised; and if any such oxide or other salt were present, unless it were very highly magnetic it would not be sufficient in quantity to account for the high values of K generally obtained. Mr. Owen raised a point in connection with the theory, which would be of importance if the maximum deflection were obtained with the specimen in the interpolar gap, but, as a matter of fact, the maximum deflection as indicated in the Paper was always obtained when the specimen was considerably out of the gap of the magnet, and consequently the position of the specimen did not become so important. An excellent datum was, however, provided by the damping sector, which had to be accurately between the poles of its magnet for perfectly free rotation, and when this was so the tube was rightly centred relatively to the gap of the deflecting magnet. No experiments had been made either as to side pull, which, however, in feebly magnetic bodies must be very slight indeed, or as to temperature. With regard to the uniformity of magnetisation of the specimen raised by Dr. Russell, he believed that some experiments on this had been made by MM. Curie and Cheneveau, but the point would have to be referred to M. Cheneveau before anything definite could be said. With regard to Mr. Crawley's point as to the cutting of the specimens and the presence of iron from the tools employed in manufacture, they had no special method of cutting the lengths and had to resort to the usual workshop processes. The experiments with acid treatment showed that although in some part the magnetic quality was a surface effect, this was by no means accountable for all, and the amount of magnetic material left on the surface from tooling was far too small to account for the values of K found. With regard to copper, the value of K certainly was due to impurity, but it was considered that the magnetic balance gave indications of the presence of such impurity with far greater reliability than any chemical test for such minute quantities. In reply to Mr. Whipple, both wood and ebonite had been tested, but not tabulated. In both these cases the results were variable, and it was practically impossible to free the material from the effects of tooling; in any case, the results always showed the specimens to be very magnetic.

CORRESPONDENCE.

NOMINATIONS FOR THE COUNCIL OF THE I.E.E.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Along, I presume, with other members of the Institution, I have received a letter signed by Mr. W. A. Chamen asking for my "vote and interest" on behalf of Mr. H. Faraday Proctor for the forthcoming election of the council of the Institution of Electrical Engineers.

I think that, with certain safeguards, the practice of the Institution nominating members for the election of the council is one that has many advantages, but I am strongly of opinion that the innovation of circularising the general body of the members in favour of a particular candidate, however eminent that candidate may be, is one that cannot be too strongly condemned, and I sincerely trust that for the well-being of the Institution the present unfortunate attempt to influence the members by circular may receive such a set back as may prevent any recurrence of it in the future.

If this practice is allowed to take root and grow, then I fear it will cause a rivalry between the members of the various local sections with regard to representation on the council, that will seriously detract from the usefulness of the Institution.

I do not say that the method adopted by the council of putting forward a bare list of the names necessary to fill the vacancies on the council is an ideal one, but I think that in nominating three prominent members of local sections they have taken a step in the right direction, and one that is likely to commend itself to the general body of the members.

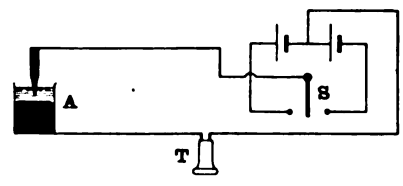
I have no personal feeling with regard to Mr. Faraday Proctor, who, I believe, would make an extremely good member of Council, but I do think that this attempt to influence members is one that will seriously affect the influence of the Institution, and I trust, therefore, that it will not receive the support of the general body of the members.—I am, &c.,

Liverpool, May 14. THOS. L. MILLER.

TELEPHONE RELAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: After listening to Mr. S. G. Brown's interesting Paper on "A Telephone Relay," read before the Institution last Thursday, it occurred to me that the effects which his new microphonic contact exhibits were, to a certain extent, analogous to those I had noticed in some recent experiments. The apparatus I was using at the time consisted of a modification of the well-known "wheel coherer"—the invention, I believe, of Sir



Oliver J. Lodge—in the form of a very fine steel needle, mounted on a vertical adjustment screw, and so arranged that its point was capable of dipping into a cup of mercury placed underneath.

The surface of the mercury was covered with a layer of oil, and the apparatus was connected up to a telephone receiver and a pair of dry cells fitted with a reversing switch. A represents the steel-mercury combination, T the telephone and S the two-way reversing switch.

On screwing down the steel point it was found that the steel apparently pierced the surface of the mercury for quite an appreciable distance before any current flowed through the telephone receiver, due to the presence of a thin film of oil—the passage of a current could, of course, at once be detected by breaking the circuit.

If now the switch S were left on the right-hand contact—*i.e.*, with the steel negative—it was found that, with the steel adjusted as above, whereas no current was flowing at first, a weak one very soon started, and gradually increased in value till there was quite a loud click in the telephone on breaking the circuit. On now raising the steel a very minute distance it was discovered that the arrangement was very sensitive to movement of the steel, and that very large fluctuations in current followed minute variations in the position of the steel.

If, however, the switch were thrown over to the left, so as to make the steel positive, the effect entirely disappeared.

The influence of different oils was tested, but among those tried ordinary glycerine seemed about the best. The phenomenon was quite a stable one, and could easily be reproduced at will immediately the point was made negative.

It seems that in action this greatly resembles Mr. Brown's microphonic contact, and that possibly the oil plays a more important part in the working than he seems to make out—at

Digitized by Google

least, from what he says in the appendix, viz., that its function is merely to promote a slight oxidation of the surfaces of the osmium-iridium alloy of the contacts.

The general impression created by the statements in the Paper seems to be that the action of the microphone is explained by the passage of electrons across the air-gap; but how can this be the case if the air is excluded by oil? Of course, the electrons might as well flow across oil as air, but when one considers that the majority of oils are good insulators—*i.e.*, that there are very few free electrons in any given volume—this does not seem to be a very plausible explanation.

I should be glad if a good explanation could be given of this action, as it would most probably fit both phenomena since they seem so allied.

Whether the apparatus that I have described above would have any use in connection with telephone relays remains for further experiments to decide, but the fact that both pieces of apparatus "work best" when the point is negative seems significant.—I am, &c.,

Muswell Hill, N., May 10. PHILIP R. COURSEY.

EFFICIENCY OF SHORT SPARK METHODS OF GENERATING ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue Mr. Galletti gives an estimate of the efficiency of transference of oscillatory energy from the primary to the secondary of a generating set. The argument on which the calculation is founded is as follows: (1) With the secondary not coupled to the primary the power input P_1 is equal to the wastage W_1 in the primary. (2) With the secondary coupled to the primary, the power input P_2 is equal to the wastage W_2 plus the power U transferred to the secondary. Taking $W_1=K_1i_1^2$ and $W_2=K_2i_2^2$, where i_1 and i_2 are the primary currents in the above two tests, we get $P_1=K_1i_1^2$ and $P_2=K_2i_2^2+U$.

By assuming that (*a*) $P_1=P_2$ and that (*b*) $K_1=K_2$, Mr. Galletti obtains the efficiency $U/P_1=(i_1^2-i_2^2)i_1^2$. Even if assumption (*a*) be allowed, exception must be taken to assumption (*b*), as K_1 and K_2, the effective resistances of the primary in the two tests, being resident almost wholly in the spark, undoubtedly depend on the currents i_1 and i_2. As a fact, if $i_2<i_1$ then $K_2>K_1$, and the proper expression for the efficiency is $(K_1i_1^2-K_2i_2^2)/K_1i_1^2$. If K_2 be taken as only twice K_1 in Mr. Galletti's case, where $i_1=2i_2$, the calculated efficiency falls from 75 per cent. to 50 per cent., a figure near to that obtained by us. It would be interesting to know on what grounds your correspondent bases the questionable premises underlying his calculation.—We are, &c.,

South Western Polytechnic Institute. W. H. ECCLES.

TEMPERATURE COEFFICIENT OF COPPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the correspondence which has appeared in your last two issues, occasioned by your review of our book on "Electric Cables: their Construction and Cost," it appears that the original subject has been dextrously displaced by a discussion on the merits of the temperature coefficient recommended by the Engineering Standards Committee.

This recommendation is contained in paragraph No. 4 of the Committee's revised report, and reads: "Resolved that the average temperature coefficient of 0·00238 per degree Fahrenheit be adopted for commercial purposes."

This, as it stands, can only mean that the Committee recommend the use of so-called "logarithmic" coefficients, and, therefore, for example, the coefficient for a difference of 28°F. will be the natural number corresponding to the logarithm

$$28(\log 1{\cdot}00238)=0{\cdot}02890692;$$

that is,

$$R_{32\,F.}=\frac{R_{60\,F.}}{1{\cdot}06883}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (i.)$$

It is, however, usual for commercial purposes to adopt a temperature resistance equation of the form

$$R=r(1+\alpha t).$$

But the above resolution cannot be concerned with this form, because no mention is made as to the standard temperature, and we should therefore be led into chaos, since we have, for example

$$R_{70}=R_{60}\{1+0{\cdot}00238(10)\}=1{\cdot}0238R_{60},$$

and again—

$$R_{60}=R_{70}\{1+0{\cdot}00238(-10)\} \text{ or } R_{70}=1{\cdot}02438R_{60}.$$

However, this being the resolution of a Standards Committee, and finding that the preceding three resolutions specifically mention 60° F. as the standard temperature, one is tempted to fill in the void of paragraph 4, thereby obtaining the formula $R_t=R_{60}\{1+0{\cdot}00238(t-60)\}$, which would meet the case of 99 per cent. of electrical resistance tests (60°F. being the standard temperature for comparison except in the limited field of submarine cables) *providing* the coefficient 0·00238 is correct. This formula gives

$$R_{32}=\frac{R_{60}}{1{\cdot}0714}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (ii.)$$

Now, I understand that Messrs. Clark, Forde and Taylor give as the result of their experiments

$$R_{32}=\frac{R_{60}}{1{\cdot}06665}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (iii.)$$

whilst the table given in our book (p. 89) shows

$$R_{32}=\frac{R_{60}}{1{\cdot}0632}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (iv.)$$

Which of these four coefficients best meets the case of commercial copper conductors must be decided from everyday practice, and not from a few experiments.

The two coefficients derived from the E.S.C.'s recommendations are ridiculously high, and can be at once discarded. With regard to the coefficient given in our book, I have found this to be reliable in all cases and it is used, I understand, by the majority of cable manufacturers. Messrs. Clark, Forde and Taylor's coefficient I have always found to be too high, although I believe it is used by one or two cable firms—one of which, however, repeatedly obtains inaccurate results when the temperature difference is at all appreciable.—I am, &c.,

Old Charlton, Kent, May 14. F. O. HOWE.

SWITCH AND TRANSFORMER OILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the discussion of Messrs. Mellis and Digby's Paper on Switch and Transformer Oils, published in THE ELECTRICIAN, April 29th, Mr. Pollard claims that alkali in a transformer oil would not be detected by phenol phthalein when the oil was shaken up with water.

It is true that the free alkali in soaps may be estimated by taking advantage of the fact that phenol phthalein is unaffected by the soaps of alkali metals in "alcoholic" solution. In aqueous solution, however, the case is totally different since hydrolysis takes place liberating free hydroxyl ions (*see* Lewkowitsch I., 56, and Mellar's "Chemical Statics," 212), which react strongly alkaline to phenol phthalein.

The same is true of alkaline carbonates and alkali salts of naphthenic and sulphonic acids, sometimes present in oils. Accordingly, exceedingly minute traces of alkali, whether present as carbonate, soap or combined with petroleum acids, can readily be detected in the aqueous extract by phenol phthalein, when oils containing these compounds are shaken up with "water."

Imperial Oil Works, Salford, JAS. ED. SOUTHCOMBE.
May 10.

We have submitted the above letter to Mr. Pollard, from whom we have received the following reply:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Southcombe's assertion, in his letter dated the 10th inst., that I claim "that alkali in a transformer oil would not be detected by phenol-phthalein when the oil was shaken up with water" is not warranted by any statement of mine.

Digitized by Google

In replying to the discussion I said "It seems to be generally taken for granted that the alkali in oil invariably exists as hydroxide. This is very far from being the case; and, consequently, when phenol-phthalein is used as an indicator considerable traces of alkali escape detection."

The following particulars of recent experiments prove that a comparatively large quantity of sodic carbonate (Na_2CO_3) in aqueous solution gives no indication of alkalinity with phenol-phthalein:—

1. In 10 cc. of neutral distilled water (having a specific conductance of somewhat less than three reciprocal megohms) cochineal gave a sharp and distinct reaction with 0·00003 gm. of sodic carbonate, added in aqueous solution: methyl orange gave a distinct change of tint with the same quantity of sodic carbonate; whilst phenol-phthalein required 0·0004 gm. of sodic carbonate before giving a feeble indication.

2. In 20 cc. of extremely faintly acid distilled water (specific conductance, four reciprocal megohms) 0·00006 gm. of sodic carbonate gave a decided reaction with cochineal; but 0·0008 gm. of sodic carbonate was required by phenol-phthalein.

3. In 20 c.c. of distilled water, of approximately the same quality as that used in experiment No. 2, cochineal gave a sharp indication with 0·95 c.c. of solution of sodic carbonate containing one part in ten thousand; whilst phenol-phthalein took 12·75 c.c. In this experiment the solution of the carbonate contained a large proportion of the faintly acid distilled water.

Mr. R. T. Thomson's researches on indicators quoted by Sutton (volumetric analysis) and Crookes (select methods) go to show that phenol-phthalein is not a suitable indicator of alkalinity when "soda exists as hydrate along with sodium carbonate if the proportion of carbonate is large"; that in the estimation of alkali existing as carbonate and bicarbonate phenol-phthalein requires tedious boiling with carbonates of fixed alkalis; that it gives results considerably too low if sodium silicate is present, and "for the estimation of soda in borax is utterly useless."

Soap is hydrolysed by water to only a very limited extent (Wright and Thomson, "Journ." Soc. Chem. Ind., IV., 630); and Mr. Southcombe's opinion, that "exceedingly minute traces of alkali," whether present as carbonate, soap, &c., can be readily detected in the aqueous extract by phenol-phthalein, does not exactly coincide with that of other investigators.—I am, &c.,

F. Ernest Pollard.

28, Victoria-street, Westminster, May 17.

PAUL'S NEW UNIVERSAL TESTING SET.

Up to within a few years ago the mains engineer was a member of that numerous class whose lot, like that of the Gilbertian policeman, was not a happy one. Although we do not wish it to be supposed that we consider nocturnal calls and midnight wanderings to investigate the results of a meandering pickaxe to be exactly an ideal condition of livelihood, yet matters are better in at least one respect than they used to be.

The respect to which we refer is in regard to testing sets. At one time a fully equipped mains engineer required to be followed by a transport train carrying the necessary instruments. Now, however, compactness is the fashion, and he can practically carry unaided all the instruments he is likely to require. This advance has been made possible by the concentration in one box of all the testing equipment which it is necessary to use on such occasions, and much ingenuity has been expended by various makers in obtaining this condition, with the result that some very interesting instruments have been designed.

Among the latest of these, and certainly not the least interesting, are the direct-reading "Unipivot" universal testing sets made by Mr. Robt. W. Paul. These sets are made in two patterns, the first of which is shown in Fig. 1. This pattern is capable of dealing with pressures between 0·0001 and 600 volts in nine ranges, with resistances between 0·00001 to 10 ohms in four ranges, and between 0·01 and 600 megohms in seven ranges, with currents between 0·000001 and 120 amperes, and with power up to 72 kw.

Dealing with the external features, the set is fitted in a strong teak case with detachable lid, lock and leather handle, and may be used on a table or other support, or a removable tripod can be supplied for outdoor use. The internal parts are highly insulated, and all electrical and mechanical details are carefully designed, the movement and switches being mounted on separate metal base-plates, supported from the ebonite front of the instrument. The terminals are plainly marked and widely spaced, they are ebonite covered to prevent accidental shocks, and there are no other external live parts. The ebonite front is fitted to the case with watertight joints; there are no openings to admit dust, draughts or moisture to the working parts, nor do any parts project when the case is closed.

The essential parts of the set comprise a direct-reading microammeter capable of being connected across a universal shunt, a series resistance for use when measuring pressures and insulations,

Fig. 1.—"O" Pattern Universal Testing Set.

two small series resistances for use when measuring millivolts, also a resistance equivalent to that of the universal shunt which is substituted for it when measuring millivolts. Two standard shunts, having their resistances adjusted to decimal parts of an ohm, are used for measuring currents by the drop at their potential points, which is read at the millivoltmeter terminals.

The microammeter is of Mr. Paul's well-known "Unipivot" construction, shown in Fig. 2, which it is claimed requires neither levelling nor setting in any particular position, and is unaffected by vibration or external fields. The movement of the pointer is quick and dead-beat and without frictional error. The single pivot on which the

Fig. 2.—The "Unipivot" Construction.

coil turns is protected from injury during transit, being lifted entirely from the jewel on depressing a plunger, either by hand or by closing the lid of the instrument; this plunger may be locked down by giving it a slight turn, and is automatically locked on closing the lid. An external adjustment provides for setting the pointer to zero should this become necessary.

All connections between the instrument and the rest of the set are controlled by a double-pole switch, shown in the centre of Fig. 3, which minimises any risk of damage by wrong connection. Further, should the negative pole be in error connected to the positive terminal of the instrument, this switch still makes it possible to read

Digitized by Google

both the current and voltage without altering the leads—an arrangement which is certainly an advantage when there is not much time to spare. Further, all the advantages of a centre-zero instrument are obtainable with a long scale of 120 divisions. This switch makes it possible to read quickly with accuracy the current and voltage on both sides of a three-wire system.

As shown in Fig. 3, the connection inside the instruments consist of two parts, that to the left of the diagram dealing with pressures and insulations, and that to the right with millivolts and current. The various parts of the instrument are g, the microammeter, having a resistance of 60 ohms, and reading from 0 to 120 micro-amperes; s, the universal shunt, having a total resistance of 600 ohms and seven shunt powers—viz., 1, 2, 5, 10, 50, 100 and 500; and r, a resistance of 20,000 ohms, designed to withstand pressures up to 600 volts.

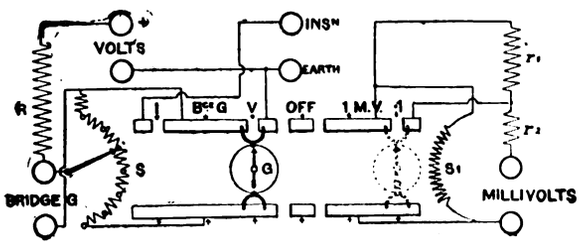

FIG. 3.—CONNECTIONS INSIDE THE TESTING SET.

Pressures applied to the terminals marked volts are read off directly on the scale, the ranges being 0·02 to 2·4; 0·04 to 4·8; 0·1 to 12; 0·2 to 24; 1 to 120; 2 to 240; or 10 to 600 volts, according to the positions of the shunt switch, which are marked with the corresponding values. An extension of five divisions at the upper end of the scale renders it possible to read pressures a little above the nominal range. For direct pressures above 600 volts an external volt box may be used.

To measure insulation the resistance under test is connected between the terminals marked Insn. and Earth. The double-pole switch is placed on v, and the deflection obtained when the test pressure is applied across 20,000 ohms. The double-pole switch is then thrown over to I, and the deflection obtained when a suitable shunt power is used with the insulation under test in circuit. Multiplying the deflection by the shunt power and dividing the testing pressure

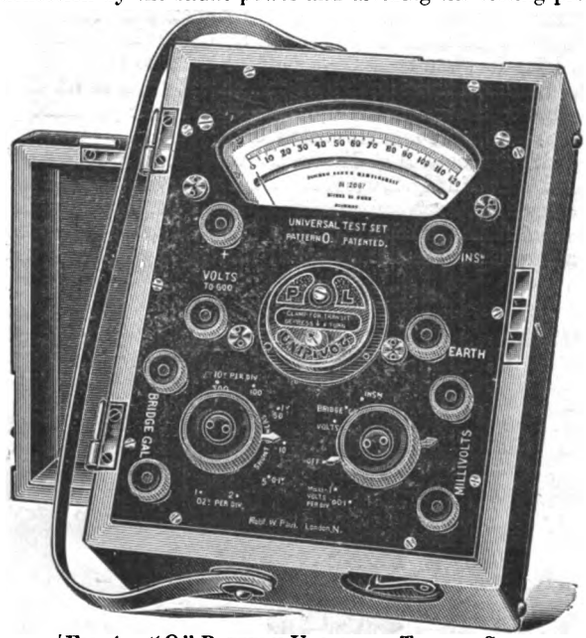

FIG. 4.—"O" PATTERN UNIVERSAL TESTING SET.

by the product gives the number of megohms. The maximum insulation readable in megohms is the same as the testing voltage available, which may be furnished either from the mains or by a portable battery. Two separate terminals, marked bridge G, render the microammeter and its shunts separately available as a sensitive galvanometer set, for use with the Wheatstone bridge or in fault localising by Murray or Varley loop tests.

The parts shown on the right of the diagram (Fig. 3) are: S_1, a resistance of 600 ohms, replacing the universal shunt so as to maintain the resistance of the microammeter circuit at its original value; and r_1 and r_2, series resistances bringing the total resistance between the millivolt terminals to either 1,000 or 100 ohms. When the double-pole switch is in the position shown by the dotted lines in the diagram, the scale reads from 0·1 to 12 millivolts; the second position giving a range from 1 to 120 millivolts. The same change-over arrangement as that mentioned above is available in this case also.

Currents are measured by one of two standard shunts, not shown in the diagram, which is joined in the circuit in which the current is to be measured; owing to the high internal resistance of the millivoltmeter, the shunt may be, if necessary, used at a considerable distance from the set, as the error due to the leads is negligible. Shunt A has a resistance of 0·1 ohm, and is used for measuring currents from 0·001 to 0·12 amperes on the lower, or 0·01 to 1·2 on the higher, millivoltmeter range. Shunt B has a resistance of 0·001 ohm, with ranges for current measurement from 0·1 to 12, or 1 to 120 amperes. Both shunts are conveniently packed in the lid of the instrument, and additional shunts may be provided, if required, for measuring up to 2,400 amperes. Very small currents may be measured at the bridge galvanometer terminals. When measuring power in a continuous-current circuit, the pressure and current may be measured in rapid sequence by turning the double-pole switch, without the necessity of changing the external connections.

Small resistances, from 10 ohms down to 0·00001 ohm, may be measured by joining them in series with one of the standard shunts and passing through them a small steady current, say between 0·1 and 10 amperes, and comparing the fall of potential across them by means of the millivoltmeter. Owing to the high internal resistance of the millivoltmeter, heavy potential connections are unnecessary. This method is suitable for measuring resistances of armatures, transformers, rail bonds, coils and similar low-resistance circuits. For measuring the temperature of electrical or other machinery, or of flues or furnaces, thermo-couples are supplied by the maker for use in conjunction with the millivoltmeter portion of the set. For use in accurate resistance measurements from 0·1 ohm to 111,000 ohms by means of the Wheatstone bridge, and for fault locating by the Murray or Varley test, the necessary additional accessories can be fitted in one case with the universal testing set without detracting from its portability. No separate ammeter is needed when using the set for locating faults by fall of potential method. When used

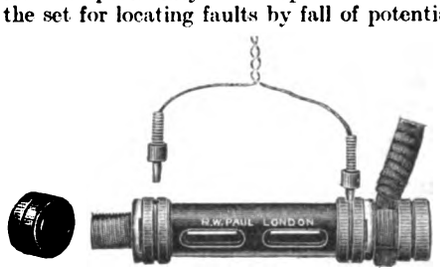

FIG. 5.—SPECIAL FORM OF TERMINAL.

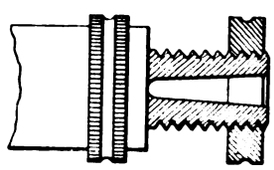

FIG. 6.—VIEW OF CONNECTION USED ON SHUNT.

as a ballistic galvanometer for comparing capacities the microammeter gives a complete throw across the scale for 100 microcoulombs, and it is frequently used in this manner for locating discontinuities in underground cables.

The second pattern testing set (Fig. 4) is similar to that described, but the scale is longer, and each division corresponds to one-fifth of a microampere. This improvement involves the use of a larger and more powerful moving coil system, the resistance of the moving coil being 350 ohms and that of the shunt 2,500 ohms, while the two series resistances in the millivolt circuit are of 500 and 5,000 ohms respectively. Further, the resistance between the volt terminals is increased to 100,000 ohms, giving an advantage in locating high-resistance faults by the fall of potential method, while an additional terminal enables this to be reduced to 20,000 when it is required to use the instrument for low-resistance work. It will therefore be seen that this pattern instrument is considerably more sensitive than that described above.

One detail of this instrument is worthy of special attention. The instrument is fitted with a translucent dial, while a hole in the back of the box permits the insertion of a special fitting containing a 2-volt lamp. In this way the scale can be illuminated at night. When not in use this lamp can be packed away in a brass case in the lid of the box.

To allow the connection of all sizes of cables to the larger shunts a special form of terminal is used, which we illustrate in Figs. 5 and 6. It consists of a copper pillar slotted out on a taper and tapped on the outside to take a circular milled head nut. The cable is inserted between the jaws of the taper and the nut screwed down until good contact is made. In this way good contact is always ensured.

We had the pleasure of inspecting one of these sets the other day, and must congratulate Mr. Paul on the results he has obtained. The set weighs only 15 lb., and is so well balanced that there seems no possibility of its ever catching its carrier in that exceedingly weak portion of the anatomy just behind the knee. This disadvantage was a feature of certain other sets. As will be seen from our illustration, the set is designed for mounting on a tripod.

SPARK-GAP PHENOMENA.*

BY J. M'WHAN, M.A.

Summary.—The author describes phenomena observed in connection with a solid dielectric placed between the terminals of an induction coil or influence machine. Experiments on the repulsion of the dielectric, the characteristics of the brush discharge, the influence of low pressures, &c., are described.

In a recent note to the Royal Society of Edinburgh,† Dr. Dawson Turner remarks on a peculiarity observed by him in the behaviour of an induction coil spark-gap when a piece of mica, glass, sulphur, ebonite, &c., is placed between the terminals, near or against the + one. The surprising variety of the phenomena exhibited on the interposition of a solid dielectric plate between the two poles of such a coil (or between the poles of an influence machine) may make the following observations (carried out in the University of Göttingen) of some interest. The observations in question were made during the course of an inquiry into the causes of the Lullin effect (according to which a thin dielectric plate interposed between two sparking terminals *not* opposite to one another is, as a general rule, perforated at the negative pole). A motor-driven influence machine whose terminals were connected through a battery of Leyden jars in cascade to a specially designed spark-gap, which allowed of any three dimensional motion of the electrodes being accurately measured and of any desired form of electrode being inserted, was used. A second spark-gap, fitted with standard spherical electrodes was connected in parallel with the first. By adjusting this second gap just to spark synchronously with the first, the P.D. of the first could easily be deduced. This method was found preferable to the use of an electrometer. Within certain limits for the dimensions of the dielectric, sparking may often be induced by placing it near or against the positive pole; and the opposite effect may be obtained by setting it at or near the negative pole. [This experiment, however, and most of the others described, will time and again *seem* to fail, owing to non-fulfilment of some one of the many limiting conditions. Thus the P.D. may not be near enough to the spark potential for free air, the dielectric may be too thick or too thin, or too broad, &c.] Even at the negative pole, however, it may be observed that if a dielectric plate be suddenly dropped vertically between the poles, a violent discharge at once takes place, and, curiously enough, more easily as a rule when the plate is so thin as to be easily ruptured by the discharge. The whole phenomenon, and particularly the violence of the discharge, is most strongly marked when, at the instant of the plate's fall, the terminals of the coil are giving off the characteristic brush discharge. Again, if the dielectric be so set up that it is at right angles to the lines of the electrodes and can be moved freely in the direction from one electrode to the other, some interesting results may be noted. Thus, if each electrode is spherical, motion of the card in the direction from the + electrode to the — electrode results in a great facilitation of the spark, while motion in the opposite direction distinctly acts as a deterrent. A little paddle-wheel, whose paddles are made of the dielectric in use, may be set up so that the paddles when rotating pass, at the lowest point, between the electrodes from + to — and provoke a steady stream of sparks. The converse of this experiment—the "quenching" of an already sparking gap by rotation in the opposite sense—is more difficult to perform, but usually can be got to succeed with a little patience. The same results are to be observed when each electrode is fitted with a conical cap, or point. But if one be spherical and one conical, an important difference comes in, for now the direction of motion for provocation of a spark is found to be *always* towards the conical electrode, no matter whether it be + or —. Also the dielectric itself is in this case under a continuous and very sensible repulsive force tending to drive it towards the spherical electrode, again quite independently of the polarity of the electrodes. There are, of course, limiting conditions to the above experiments, for example, if the angle of the conical electrode be increased indefinitely until the cone degenerates into a plane surface, the preference of the spark for that electrode naturally diminishes. It may also be noted that when a discharge followed by perforation of the dielectric has once been induced by motion of the dielectric, the difficulty of provoking a second spark discharge becomes still greater than formerly: on examining the apparatus in the dark it is usually easy to discern the faint lines of an almost silent discharge threading the hole from electrode to electrode.

Repulsion.—Doubrava has pointed out‡ that in general any dielectric plate set between discharging electrodes experiences a definite force tending to displace it in the direction of one of the electrodes. He declares, however, that "the experiment only succeeds when the electrodes are sufficiently separated to give a crackling brush discharge." This is not the case. Repulsion effects on all kinds of plates are observable even when the electrodes are speaking freely (*through* the plate, or round its edge) or discharging by the so-called "silent" discharge. In the present instance, dielectric plates (16 cm. × 16 cm.) were suspended midway between the electrodes by a fine silk bifilar suspension from insulators on the ceiling. The suspension was about 15 ft. long, a length sufficient to permit of even very small forces producing sensible deflections, and the plate itself was screened off from draughts. In the case of metal plates, however, which were also found to exhibit repulsion phenomena, one thread can conveniently be replaced by a fine copper filament leading to an electroscope screened from electrical action by fine wire gauze.

In general it was found that when the electrodes were of similar shape and size, discharge between the electrodes resulted in a strong repulsion of the plate in the direction from the + to the —. Preconceived theories of this repulsion, such as that of a possible hydro-electric excitation of the surface of the plate by the discharge, are upset when we employ electrodes of different shapes. Thus, if the sphere and cone be again used, it does not matter which is + and which —: the repulsion is always violent, and in the direction from the conical electrode to the spherical one, regardless of polarity. If the electrodes are not opposite one another, then, on reaching the sphere, the plate is rotated through a considerable angle. If the plate is not allowed to touch either electrode, but is tested immediately after the discharge, it shows always the sign of the conical electrode. When the electrodes are similar, it shows always the sign of the repelling electrode, *i.e.*, +. Another curious phenomenon occurs in the case of similar electrodes, *e.g.*, spheres. Let the plate be repelled against the — electrode, and remain there

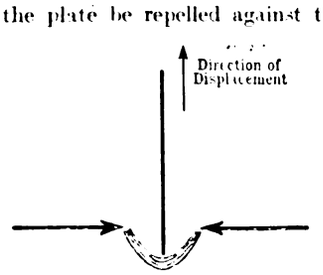

FIG. 1.

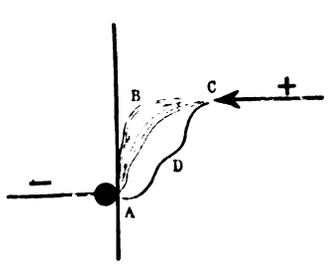

FIG. 2.

during discharge. If the electrodes are not opposite one another, it will again show rotation, but this time of the opposite sense to that mentioned above. That is to say, it behaves as if attracted simultaneously by both electrodes, but with the — electrode in predominance. This effect could not be obtained with metal plates: it may hence be inferred that different parts of the dielectric plate are in this case in different electrical conditions as regards charge.

If the plate be light enough, and the electrodes placed so near the edge of the plate that the path of least resistance for the discharge is round the edge of the plate instead of through it, a considerable horizontal displacement of the plate in the direction of its own length may take place, as shown in Fig. 1. Observed in the dark, the phenomenon is a very beautiful one, the rays of the discharge appearing like luminous elastic strings attempting, in a contractile effort to straighten out, to pull the plate aside—in fact, like luminous Faraday lines of force. The electrification of the plate is slight, and practically indeterminate as regards sign.

Brush Discharge.—When a dielectric is placed between two electrodes excited to a potential sufficient to produce the brush discharge, examination in the dark reveals some interesting details. The discharge is seen to be made up, as in ordinary cases, of a bundle of luminous threads, each pursuing a quite independent path; but at one part of their course these threads converge, and pass almost wholly through one point. This point lies *on* the dielectric (usually on the + side), is brilliantly illuminated, and is found to be in every case *the site of the perforation* consequent on the exciting of the electrodes to spark potential. Although, however, the point of concentration of the rays usually determines the point of perforation, the spark does not, except in simple cases, follow the path of the brush discharge. Fig. 2 illustrates a typical case of this, ABC being the path of the brush, ADC the approximate spark-path. The point of concentration A is common to both paths. In this case a hole made in the card between the electrodes would have no appreciable effect on the path of the brush.

Some remarkable "dark-space" phenomena can also be easily

* Abstract of a Paper read before the Royal Society of Edinburgh.

‡ "Wiedemann Annalen," Bd. VIII., p. 476.

Digitized by Google

observed or photographed. Fig. 3 gives an example: the observer is looking from above on to the spark-gap below. The + side of the card for the whole distance between the electrodes is strongly illuminated: from the — (conical) electrode proceeds little more than a point of luminous discharge—between that and the card all is dark. The rays from the + (spherical) electrode have the peculiarity of lying entirely in one horizontal plane: they, too, after bridging about one-half the gap between card and electrode, vanish abruptly, the end of the discharge being perfectly straight and regular. If, now, the card be moved slowly towards the anode, a change takes place in the character of the brush. Fig. 4 is a side view showing that change. At a certain stage in the motion, the horizontal brush suddenly splits into two brushes, each uniplanar; and as the card continues to approach, these continue to diverge, each making at any time the same angle as the other with the plane of the electrodes. Many varieties of these experiments can be designed by making holes at various points in the plates between or outside the electrodes, or by bending the plate itself into various shapes.

An attempt was made to observe the influence of low pressures in air and other gases on these phenomena, and on the Lullin effect. A strong glass bell-jar was accordingly made to contain the spark-gap and a contrivance for supporting or suspending the dielectric. The dimensions of the jar were approximately: height, 40 cm.; average thickness, 1 cm.; mean inside diameter, 25 cm. It was made in two parts for convenience of access to the interior. In the first experiment the air was exhausted to a pressure of about 4 mm. Hg and a spark passed. Instantly the lower half of the jar split, with a loud report, from top to bottom. Lehmann has observed the same phenomenon when working on discharges through gases in large vessels. The danger of breakage is, however, not entirely confined to *large* vessels. After the bell-jar had broken, it was

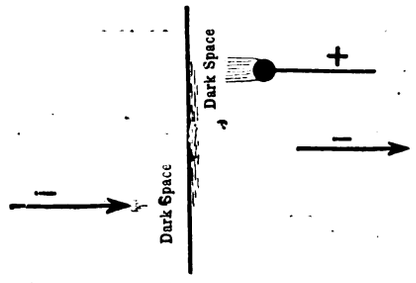

FIG. 3.

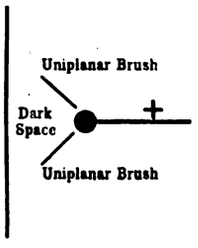

FIG. 4.

decided to abandon the idea of getting the special spark-gap bodily into the vessel. A cylindrical glass tube, 14 cm. in length and 5 cm. inside diameter, was taken instead. The ends were open, but could be closed by two plane slabs of glass, bored to allow stout pieces of copper wire (which were to do duty as the electrodes) to enter, and the whole was rendered air-tight with sealing-wax. This stood successfully the first and second discharges, but on the third the lower end of the tube was completely shattered.

In experiments as described above, the vagaries common to most electrostatic experiments performed in the free air of a laboratory are of course prominent, especially during adverse atmospheric conditions; and results on occasion display such consistent inconsistency as to baffle serious consideration. For this reason only a few phenomena, substantiated beyond reasonable doubt, have been quoted. These should be sufficient, nevertheless, to draw attention to the complete absence of a theory regarding the presence of dielectrics in a spark-gap, which will deal satisfactorily with all cases. The further surprising divergences met with when the dielectric has imposed upon it a drop or drops, of various shapes and sizes, of wax, stearine, &c., make the problem still more difficult.

ELECTRICAL CONVEYOR FOR WAREHOUSING PARCELS.

In busy cities, particularly those concerned in the textile industries, an enormous amount of lorry traffic with comparatively small parcels exists. In Manchester, for example, thousands of loads daily of yarn bundles, piece goods and the like are conveyed by lorries to and from warehouses in the city. One finds similar conditions with textiles, provisions, light hardware and so on in the City of London, and in Birmingham, Liverpool, Glasgow, Nottingham and elsewhere.

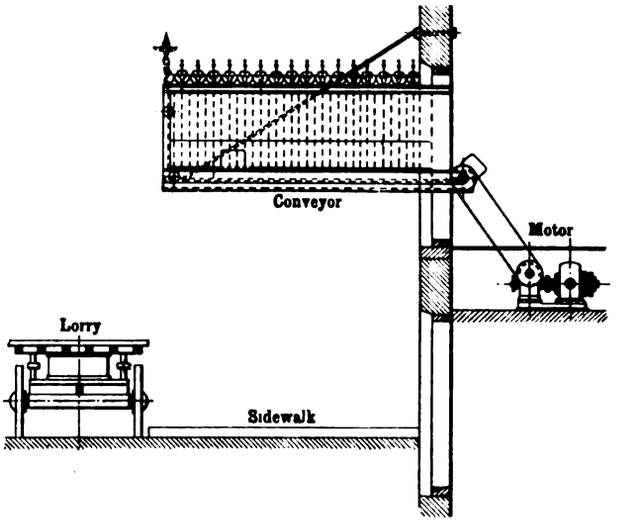
The usual practice is to build important warehouses with a frontage to a main thoroughfare, and with one or more of the other sides abutting upon a narrow side street or alley, into which the lorries draw up and from which the lorry man unloads by throwing his parcels through a window or down a shoot. The result is that during working hours these by-streets are practically impassable for pedestrians, while in London and Manchester, for example, one often sees long trains of lorries waiting for hours for their turn to unload. Then, again, there often is congestion at one side of the warehouse and comparative idleness at the front. The Corporation authorities very properly veto any such unloading as will inconvenience the general public in main streets.

One of the leading shipping houses in Manchester, who were urgently in need of additional loading and unloading facilities, recently invited Mr. T. Roland Wollaston, of Manchester, to devise a means whereby they might load and unload from and to their main frontage in Peter-street, with the result that the device, which is the subject of this notice, was designed, patented and has proved of great utility.

It was from the first recognised that the authorities would not sanction anything of the nature of an ordinary elevator hanging over the footway, nor, on the other hand, could anything which involved a high degree of skill or care on the part of the lorry man be considered. One had also to remember that any such contrivance must not unnecessarily disfigure the handsome elevation of the warehouse.

Now, permanent awnings, such as one may see at the entrances of most hotels and public buildings, are ornamental and useful as shelters, while, if fitted as cantilevers, they present no footway obstruction.

The device comprises a permanent awning of this type, with arched roof, and sheet-iron bottom, projecting out from a window of the building and across the footway, so that the front is plumb with the



GENERAL ARRANGEMENT OF CONVEYOR.

curbstone. Within the hollow trunk so formed runs a lattice conveyor belt which extends just so far within the building as is necessary for the convenient reception of the parcels. The front of the awning towards the roadway is provided with a large opening which, when the apparatus is idle, is closed by an ordinary roller-shutter door, operated and locked from within. The lorryman has simply to throw his parcels haphazard through the opening, when they fall upon the belt and are conveyed and delivered inside. The belt is driven through a Renold chain and worm-reducing gear from an ordinary Crompton direct-current electric motor. At the preliminary trial of this apparatus 600 10 lb. bundles of yarn were unloaded in 25 minutes, the rate being nearly double the highest recorded at the back of the building where similar bundles are thrown across the narrow footway through open windows.

The apparatus embodies one or two somewhat novel constructional features. The local authorities insist upon a minimum of 10 ft. of headroom under the awning, which is somewhat higher than one would wish for the lorryman's convenience in throwing in. Therefore it was necessary to keep the upper side of the travelling band as low as possible, or, in other words, to keep the end rollers or wheels small in diameter. Now an ordinary conveyor belt of cotton or leather, 5 ft. wide and to carry 10 lb. bundles, would have to be very substantial, and would not turn easily over rollers, say, 6 in. in diameter. It would be heavily stressed thereby and would absorb much power uselessly. Similarly a lattice belt formed of timber or iron slats and of the above width, carried on pitch chains, would necessarily be very heavy. The actual belt is formed of Ewart's

Digitized by Google

patent pitch chains at either side, running over end sprockets about 5 in. in diameter. Alternate links of these chains are prepared to carry pins in the ends of the slats which are composed of the metallic conduit tube commonly used for electrical wiring. These tube slats, about ¾ in. outside diameter and pitch 3½ in. apart, are very light, sufficiently strong, and present a smooth surface unlikely to damage fragile goods.

A reversing switch enables the conveyor to work either inwards for unloading or outwards for loading.

The following are approximate details:—

Width of conveyor	5 ft.
Opening for parcels	5 ft. by 2 ft. 9 in.
Speed of belt	40 ft. per minute.
Rating of motor	2 H.P.

THE JAPAN-BRITISH EXHIBITION.

The interest of engineer visitors to the Japan-British Exhibition naturally centres in the Machinery Hall. Although this is not filled with exhibits to the same extent as on the occasion of the Franco-British Exhibition, still, the show of general engineering, mechanical and electrical apparatus is well worth inspection. The Japanese section of the hall is confined to one leg of the U, which letter the hall resembles, and the remainder is devoted to British exhibits.

Japan is essentially a country of earthquakes; consequently one may expect to find the study of seismography reduced to a science. Judging by the fine examples of seismographs at the entrance to the Japanese portion of the hall this is certainly the case. The Imamura seismoscope is displayed together with a number of records taken on it. Also the Omori tremor recorder and a collection of seismograms. The instruments utilise electricity in a portion of the recording mechanism, and we hope to return to a more detailed description of them later. At the time of our visit to the Exhibition the stand was unattended and no particulars could be procured.

The Imperial University of Japan exhibits a large collection of portfolios containing drawings by the students. The electrical engineering portfolio gave full details of a direct-current generator. Beyond a section of a Japanese centrifugal pump and examples of a wood-testing machine, there does not appear to be anything further of engineering interest in the Japanese section.

The feature of the British section is the textile machinery exhibit which has been made by a number of Lancashire manufacturers. Prominent among these is the display by Platt Bros. & Co., who have installed machinery which shows practically the whole of the operations performed on cotton from the bale to the finished goods—both fine and coarse. This machinery is grouped on each side of the central aisle in the Machinery Hall. Electric driving has been adopted and the one-half of the machines is belted to countershafting driven by a polyphase motor, the other half being operated in a similar manner by a direct-current motor. The alternating-current motor is a 40 H.P., 525 volts, 50 ∿, 575 revs. per min., slip-ring machine, and is connected to the shafting by three cotton ropes. A weft ring frame is driven by a 15 H.P., 962 revs. per min. motor, which drives the main shaft through a Hele Shaw clutch. This latter is provided to give smooth starting so as to avoid "breaking down the ends." Included on the stand driven by the alternating-current motor is a spinning mule which makes a difference of 15 amperes to the load, when the mule is drawing out. The direct-current motor is a 60 H.P. machine, running on 500 volts at 600 revs. per min. It drives the bale opening, breaking and blowing machinery on the other stand. The exhibit is quite the most interesting collection of textile machinery demonstrating progressive stages of cotton manufacture that we have seen.

There is a good collection of electrical exhibits which include Chloride accumulators, Linolite, Float Battery lamps, Sturtevant fans, Dugdill pendants, Maxim lamps and Western Electric telephones. Electromotors (Ltd.) have a display of their standard direct-current machines, both as motors and dynamos. The exhibit also includes a motor generator supplied at 500 volts from the Exhibition network and delivering current at 250 volts within the Machinery Hall.

The General Electric Co. have a brilliant display of Osram lamps, which are shown in sizes from 2 to 400 c.p., and they are also making a special demonstration of "Striplite," which has been designed to comply with the L.C.C. requirements for showcase lighting.

The heavier machinery exhibits are provided by Armstrong, Whitworth, Vickers, Sons & Maxim and the Thames Ironworks & Shipbuilding Co. These firms show models and photographs of ships built for the Japanese Navy and parts of guns, gun carriages, Maxims, &c. Armstrong, Whitworth have put down some large machine tools, a lathe, boring mill, shaper and slotter, each of which is driven by independent electric motors. Vickers also make a good show with various types and sizes of electric motors, both alternating current and direct current and suitable controlling gear. Mounted high above the stand is the barrel of a 12 in. gun.

The general illumination of the Exhibition is, of course, entrusted to electric lamps, and at present the outlining of the buildings is still done with carbon lamps. Metal filament lamps are, however, to be seen in large numbers throughout the various buildings and stalls. We shall return to a more detailed account of the electrical features of the Exhibition in an early issue.

SIEMENS WORKS AT WOOLWICH AND DALSTON.

We have received from Messrs. Siemens Bros. & Co. a well-illustrated description of their works at Woolwich and Dalston. The former of these, as is well known, was established in 1864, and until 1904, when the dynamo and motor branch was transferred to Stafford, was the scene of all this firm's manufacturing activities in this country. At the present time the works are fully employed in making submarine cable, as well as cables for electric light and power purposes. Further, there are well-equipped cabinet-making shops as well as shops in which instruments, railway signalling apparatus and batteries are turned out. In connection with all these operations there is a very complete testing department, while

FIG. 1.—PART OF INSULATING TAPE SHOP.

the whole works are supplied with electric power from a private power house containing five 300 H.P. engines. Some new photographs of these works are given herewith.

The Dalston works are, as is well known, a comparatively recent outlet for the firm's activities in manufacturing Tantalum lamps. They were opened in 1908, and contain on the ground floor a general packing and despatching department, as well as a receiving department and fitting stores. The rest of the works is devoted to the manufacture and storage of Tantalum lamps, ventilating, heating and transforming machinery being situated in the basement, while out-buildings on the south side contain the necessary generating station for the supply of light, power and other auxiliary machinery. Special precautions are taken to protect the buildings from fire, a system of sprinklers and fire alarm indicators, under the control of the company's fire brigade, being installed.

The many processes involved in the manufacture of Tantalum lamps are carried on to a certain extent simultaneously, but the following description illustrates approximately the manner in which the lamps are built up and completed for sale. A Tantalum lamp consists essentially of three parts, namely, the "foot," the filament and the glass bulb. The "foot" is made up of flanged sealing-in tube with leading-in wires, and the "spider" or filament support. The flanged tubes are formed in the following manner: A glass tube is cut up into suitable lengths and these are inserted into a specially designed revolving machine, one end of each tube being brought into contact with a gas flame. When sufficiently hot a device is pressed into the tube so as to form a flange or funnel, and the flanged tube is then complete. The copper leading-in wires are finished off by being brazed on to short pieces of platinum wire,

Digitized by Google

which, in turn, are brazed on to copper electrodes. The "spider" consists of a small glass rod, on which two buttons are worked up, a radial set of copper wire arms being inserted into each button while hot. The various component parts of the "foot" are now assembled in the shop, where they are put together in a specially constructed machine. The portions that have to be melted together

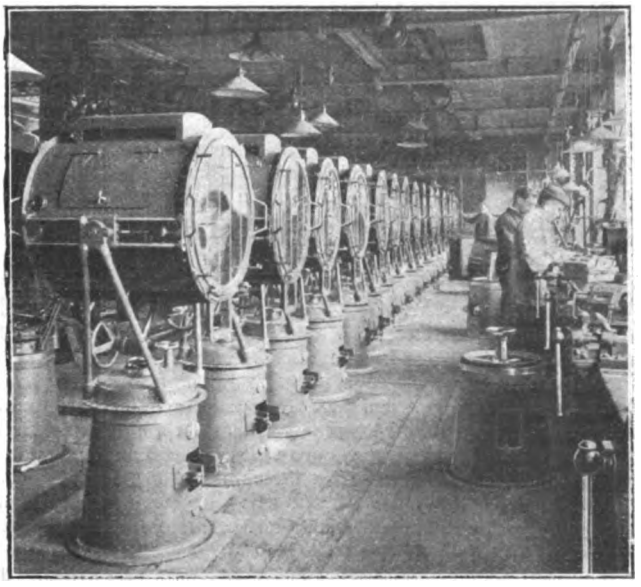


FIG. 2.—PART OF FITTERS' SHOP.

to make the "pinch" are gradually heated in the gas flames until they are sufficiently hot, when they are squeezed or pinched together, an operation requiring great care.

The "foot," being completed, is now ready to go to the winding room. Here the copper arms of the "spider" are pulled into shape and the hooks are made on which the tantalum wire is wound. The operator measures off suitable lengths of tantalum wire, one end of which is pinched into the tube which has been formed at the end of one of the copper electrodes; the wire is then wound round the arms of the spider and the other end is pinched into the second electrode.

The filament being now wound on the "foot," the next operation is that known as "sealing-in," by which the complete foot is melted into the bulb. But the bulb has previously been stemmed for exhausting, a small hole having been blown in the bottom of the bulb, to which a piece of stemming or exhausting tube has been joined on, an operation requiring some skill, as it is at this point that the lamp is finally sealed to form the "pip."

The first operation involved by sealing-in is to cut off the neck of the bulb evenly, and at the right distance from its shoulder, so that the filament will occupy its correct position in relation to the shape of the bulb. This having been done effectually, the "foot" is placed in the bulb, with the flanged part of the tube about ¼ in. up the neck; this point is then brought into a gas flame and rotated on a special machine, so as to obtain even heating, the bulb neck being melted thoroughly on to the flange, thus making absolutely an air-tight seal. The sealed-in bulb is then placed in an annealer and allowed to cool slowly.

The next process is that of exhausting the air from the bulb. The lamps are sealed on a vacuum pump by the stemming tube being connected, firstly, to the rough or "fore" vacuum pump, which exhausts the greater part of the air, and then to the fine or finishing vacuum pump.

When the vacuum has reached a certain degree current is passed through the filament, in order to drive off any occluded gases. During this operation also the lamps are subjected to great heat by means of so-called "heating caps," with the object of driving off any air which may be adhering to the inside of the glass bulb. Finally, the current is switched off and the lamp is sealed off by means of a small pointed gas flame, the "pip" end of the lamp being formed by this means.

This operation concludes the general manufacturing processes, but the lamp has yet to go through an important series of tests before being finished off for sale. The first test is for vacuum. This is carried out by means of an induction coil in a dark room. The operator holds the lamp in the hand and connects the leading-in wires to one or other of the secondary terminals of the coil. All lamps showing any sign of glowing, which indicates a poor vacuum, are tested for continuity of circuit, and are then placed on a frame for "running," *i.e.*, the current is passed through them to make them incandesce for a considerable period. The vacuum is tested again in the manner already described, and any lamps which show signs of faultiness are discarded.

FIG. 3.—INSTRUMENT SHOP.

The next process to which the lamps are subjected is that of testing voltage and candle-power. This is carried out in the photometer room, where the candle-power is read off on a scale against a standard lamp, and the voltage and current are measured simultaneously by instruments.

When the lamps leave the photometer room they are sorted into groups, according to the voltages indicated by the previous tests,

Digitized by Google

They are then sent into the capping and finishing room to be capped, cleaned and stamped with voltage marks, &c. Those that have to be obscured are taken to another room, where they are inserted in a machine specially devised for this purpose.

Although the lamps are now complete, it is considered desirable to make further tests, as they are subjected to another vacuum test, this time with an oil transformer having a secondary pressure of 10,000 volts. They are then placed again on circuit to test for continuity and equality of light, in order to make sure that no lamp of the wrong voltage or candle-power has been passed through. Finally, they are sent to the wrapping shop and thence to the store, where generally they do not remain long before entering the packing and despatching department.

The Dalston works, of which we regret we are not in a position to give any illustrations, are supplied with power from two 165 H.P. 220 volts Belliss-Siemens sets contained in a separate building. Alternating current at a pressure of 200 volts is generated by means of two motor-alternators, this arrangement being selected as the tests made on the lamps are therefore more stringent than if continuous current were used. Continuous current is supplied from a battery.

THE MOTOR APPLIED TO BREAKDOWN WORK.

An interesting example of the way in which the electric motor can be easily and quickly applied to the rectifying of accidents is shown by a case which recently occurred at Blackburn. The machinery which was driving the Struan Mill in that town, belonging to Messrs. John Yates, broke down about a fortnight ago, on Friday, April 29th,

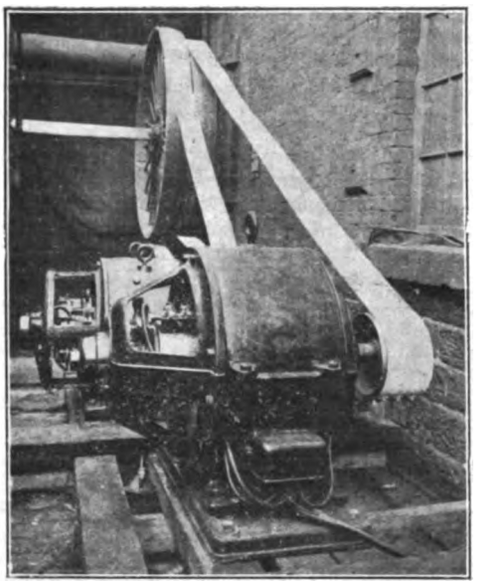

FIG. 1.—TWO MOTORS RUNNING IN PARALLEL AND DRIVING THE SAME SHAFT.

to be exact. On that day one of the teeth on the second main pinion wheel on the main shaft of the mill broke, with the result that the big fly spur wheel became jammed by the broken bits and three of its teeth were also broken off. The resulting damage was that all the bearings and gearing were smashed, the shaft was strained, and the mill, which contains 820 looms, was brought to a standstill.

A consultation was at once held as to how soon the mill could be again set running, for the firm were engaged on several important contracts, and every day's stoppage meant a serious loss. The owners were informed that the repairs would require a period of at least three weeks. On account of this lengthy time they, therefore, communicated with the electricity department of the Blackburn Corporation, with a view to discovering whether electric power could be obtained temporarily from the mains. We are glad to be able to say that this arrangement was quite possible; while the speed with which Mr. P. P. Wheelwright, engineer and manager of the Blackburn electricity department, and his staff worked to get things going again reflects great credit on all concerned. This very practical example of the way in which the electric motor can be quickly applied to all classes of work should not be without its effect upon the directors of the Struan Mill, and doubtless other cotton manufacturers both in Blackburn and the surrounding neighbourhood will now see much virtue in the new arrangement.

Mr. Wheelwright received information of the affair at noon on the Saturday, and by Monday morning a motor was installed in the top shed of the mill, and was driving 100 looms out of the 820, being connected to the shafting through a belt and a large temporary pulley. On Tuesday morning another motor had been put down, also driving 100 looms, while the following morning the third motor had enabled another 100 to be re-started.

This desirable state of things was not reached without considerable difficulty, as the motors themselves had to be brought into the shed in parts and built up, while a switchboard had to be erected, as well as the necessary wiring operations effected. This having been done successfully, on Thursday morning 250 looms out of the 400 in the bottom shed were re-started by connecting up two motors with the driving shaft. In this connection we may call attention to an ingenious arrangement which was adopted for this purpose. The electricity department did not possess a motor of sufficient capacity to drive 400 looms at the right speed. They, therefore, employed two smaller motors whose normal speeds and capacities, however, were different. This difficulty was got over by carefully adjusting pulleys on the shaft, and more exact adjustment was obtained by slightly speeding up one motor and slowing down the other, the two motors being run in parallel, driving the same shaft. By this means 250 looms were quickly set running and have been working satisfactorily since. Fig. 1 shows this interesting arrangement, and Fig. 2 one of the other drives.

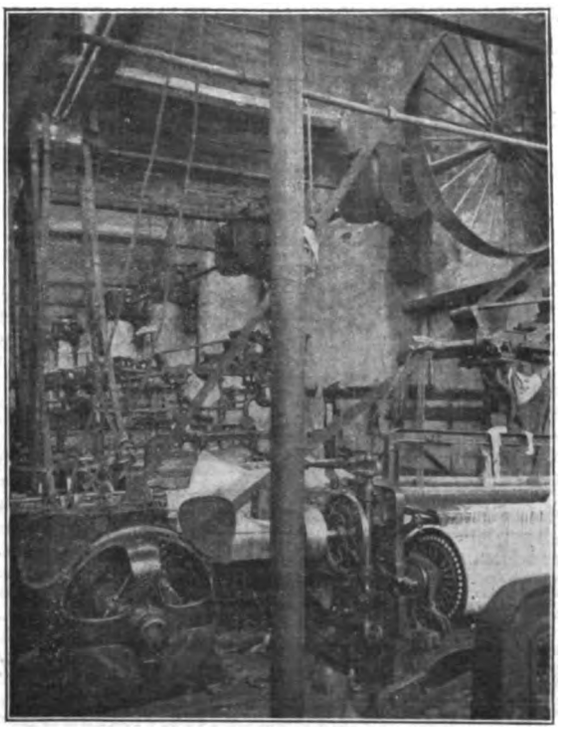

FIG. 2.—MOTOR ARRANGEMENT IN THE STRUAN MILL, BLACKBURN.

It should also be noted that overtime has been worked on 350 looms for two hours every evening. The Corporation electricity department have, therefore, been successful in arranging for the mill to work at its full capacity in spite of the breakdown.

We must congratulate both Mr. Wheelwright and his staff for taking such good advantage of an opportunity for showing the possibilities of the application of the electric drive to textile work. As our contemporary, the "Blackburn Weekly Telegraph," remarks: "Certainly the affair seems to open up wide possibilities in the direction of running mills by electric motor power," and we hope that this point will be duly appreciated.

LEGAL INTELLIGENCE.

Tramway Assessment Appeal.

Sheriff Gardner Millar, Glasgow, heard an appeal last week of the Lanarkshire Tramway Co. against the valuation of £18,826 placed by the assessor of railways on the company's lines in the county. After hearing the parties, the Sheriff fixed the valuation at £15,725, with no costs to either side.

Digitized by Google

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT.

The Council of the University of Manchester require an assistant lecturer and demonstrator in the department of physics. Applications to the Registrar by June 13.

The professorship of physics at University College, Reading, will shortly become vacant. Particulars from the Registrar.

A junior lecturer and demonstrator in physics is required at the University of Sheffield. Salary £150 per annum. Applications to the Registrar by June 1.

Australasia.—The Victorian Minister of Railways (the Hon. W. Billson) has made an important announcement in regard to the electrification of the suburban railway system.

He said there was only one policy that should be followed, and that was the policy initiated by New South Wales Government in Sydney of the electrification of the means of transit between the city and its suburbs. He was convinced that that system must be introduced in Melbourne without delay, and he intended to make an earnest effort to get the Government and Parliament to approve of the electrification of the whole of the suburban system.

Austria-Hungary.—Budapest Tramways Co. intend to increase the capacity of their generating station from 6,500 kw. to 13,000 kw. The company are said to contemplate additional capital expenditure of £187,500.

Prague Municipality have voted £62,500 for the construction of electric tramways.

Birmingham.—The report of the Electric Supply committee for the year ended March 31 states that the total units generated were 29,079,276, against 24,406, 227 in 1908-9.

For lighting and power 12,254,931 units of low-tension current were supplied, against 10,796,024; 4,677,922 units of high tension current were supplied for power, against 1,827,794; and for traction 12,146,423 units, against 11,782,409 units. The receipts were £186,345, compared with £175,896 in 1909. Private lighting and power output again show a satisfactory increase (34·13 per cent.), but the receipts only show an increase of 7·8 per cent. owing to lower prices for current. The revenue account is also debited with £4,257. 4s. 1d. in respect of new meters. In 1908 the Council obtained sanction to a loan of £4,000 for meters, but the L.G. Board only granted a period of five years for the repayment of the loan. Having regard to the shortness of the period and the consequent heavy payments for sinking fund, the committee decided to purchase meters out of revenue. The sanction to the loan will not be acted upon, and the amount spent on new meters during the past 2½ years has been transferred to revenue account. A sum of £1,520. 6s.6d. for service switches installed on consumers' premises is also included, as it has been decided to pay for these fittings out of revenue rather than apply for a loan, seeing that only a short period would be granted. In addition, the revenue account contains special expenditure amounting to £12,110. 3s. 2d., in respect of the reconstruction of Dale End station and offices and alterations at Water-street and Parker-street stations; also £2,351. 11s. in respect of plant abandoned at Parker-street substation. The balance (£93,588. 2s.) represents the gross profit, and after meeting all charges for interest and sinking fund there remains £19,255. 10s., of which £9,000 has been placed to renewals fund, leaving a surplus of £10,255. 10s., which it is proposed to pay to credit of improvement rate. The net increase in lamp connections (lighting only) amounted to an equivalent of 13,378 16 c.p. lamps, against 24,691. The net increase in motors connected amounted to 5,720 H.P. (4,267 kw.), against 4,869 H.P. (3,632 kw.). The total length of new mains laid during the year was 20,680 yards, against 29,316 yards. The work of installing additional plant at Summer-lane station and various substations is approaching completion, and it is necessary, in view of the steady growth of the output, to make provision to continue the installation of additional plant. According to estimates prepared by the engineer (Mr. R. A. Chattock) by the end of 1914 the demand may reasonably be expected to reach 27,000 kw. To meet this increased demand it is proposed to instal 11,000 kw. of generating plant at Summer-lane station, bringing its generating capacity up to 31,500 kw. This addition will complete the equipment of the station. The original estimate of the capacity of the station was 26,500 kw. The installation of 5,000 kw. of additional plant is rendered possible by the adoption of exhaust steam turbines. There will also be available at Water-street station generating plant of a capacity of 2,000 kw. giving in 1914 a total generating capacity for the whole undertaking of 33,500 kw. The extensions proposed also include the building of a small sub-station at Harborne, and its equipment with 400 kw. of distributing plant. Applications have been made for a supply of current in this district, and the prospects justify the erection of a sub-station of this size. The estimated cost of the extensions proposed (including £1,000 for Harborne) is £143,250.

The great development in the work of the department has compelled the committee to consider the question of relieving the city electrical engineer of some of his various duties. At present Mr. Chattock also acts as manager of the department, and the committee do not propose to alter this arrangement, but to appoint a secretary, who, under the engineer, shall take control of the commercial, secretarial and accountancy sides of the undertaking. The committee do not think that they are likely to obtain the services of a man having the necessary experience for less than £600 per annum, and they recommend that they be authorised to make the appiontment at this salary.

Blackburn.—The borough electrical engineer (Mr. P. P. Wheelwright) is preparing a scheme for the electric lighting of Corporation and Queen's Parks.

Bolton.—The borough electrical engineer and tramways general manager (Mr. A. A. Day, A.M.Inst.C.E.) has reported to his committees on the results of the past year's working as follows:—

The revenue was £60,527. 18s. 6d. (1·21d. per unit sold), works cost £21,837. 1s. 6d. (0·414d.), and total cost £26,749. 18s. 6d. (0·513d. The capital items paid out of revenue came to £2,715. 8s. 9d. (0·055d.), interest absorbed £8,563. 3s. 2d. (0·171d.), sinking fund £14,583. 12s. (0·292d.) and depreciation £4,664. 8s. (0·094d.). The inclusive cost was £56,252. 8s. 3d. (1·125d.) and the gross profit £34,941. 9s. (0·799d.). The percentage of operating cost to revenue was 44·19, the amount brought forward was £2,680. 6s. 1d., and the nett profit was £8,119. 5s. 4d. (0·162d.). The average price obtained was 1·18d. per unit. £6,000 was devoted to relief of rates; the gross capital is £359,690 and the nett capital £242,557.

The revenue of the tramways department was £122,528. 1s. 3d. (11·134d.) per car-mile, and operating costs were £72,436. 18s. 5d. (6·582d.), the percentage of operating costs to revenue being 59 per cent. The traffic expenses were £28,406. 13s. 10d. and the general expenses £7,375. 14s. 11d., repairs and maintenance came to £16,724. 17s. 8d., and power cost £19,947. 12s. 2,641,292 car-miles were run, and 27,018,149 passengers carried. £7,866 was paid in relief of rates. The gross capital expenditure is £504,694 and the net capital is £375,248.

Brighton.—For the year ended March 31 the revenue of the tramways department was £51,358, compared with £47,809 in 1908-9. The number of passengers carried shows an increase of nearly 750,000. The net profit was £1,190, against a deficit of £2,420. The cost of repairs and renewals to permanent way increased from £3,459 to £4,005 owing to the great charge for maintaining the wood-paving.

Bulgaria.—Philippopolis Communal Authorities will shortly invite tenders for the provision of electricity supply and electric tramways.

Colwyn Bay.—The Council have obtained sanction to a loan of £2,500 for cable extensions to Old Colwyn.

Cornwall.—Camborne Council have been informed by Cornwall Electric Power Co. that the company propose to erect a power station at Hoyle and electric current will be transmitted from there by overhead cables to the Dolcoath and other mines.

Dundee.—The receipts of the tramways department for the past year amount to £61,233, compared with £61,869 for 1908-9. The number of passengers carried was 16,836,571, compared with 16,988,331.

The Scottish Office have granted increased borrowing powers for the electricity department to the extent of £50,000.

East Ham.—To encourage private arc lighting among consumers who provide their own installation and lamps, the Electricity committee have decided that, instead of metering the current, a fixed charge of 5s. per lamp per quarter is to be made for each arc lamp installed, and a fixed rate per hour for each hour the lamps are burning during the quarter, this amount to be measured by an ordinary clock meter. The scale is as follows:—

For ordinary enclosed type lamps in series: Up to 6 amps. 1d. per lamp per hour, 7 amps. 1·2d., 8 amps. 1·4d. For open type of flame arc lamps: Four in series, up to 10 amps. 1d. per lamp per hour, 12 amps. 1·2d.; three in series, 6 to 8 amps. 1d.; for double carbon single lamps, up to 3½ amps. 1·4d.; for double carbon single lamps, up to 4 amps. 1·5d. On the hire system the present inclusive charge of £2. 2s. per lamp per quarter is to be reduced to £1. 11s., and the present charge of 2½d. per lamp per hour for all hours in excess of 800 per annum is to be reduced to 2d. The reductions come into operation on July 1.

Exhibition.—A Smoke Abatement Exhibition will be held at the Victoria Skating Rink, Glasgow, from Sept. 16 to Oct. 8. The exhibition is being organised by the Corporation, and the exhibits will include appliances for lighting, heating and cooking without smoke.

The Corporation decided to hold the exhibition in consequence of reports by experts and by special committees appointed by the Corporation to consider the matter. The charge for space for exhibits will be very low, and electrical energy and gas will be supplied free. Further particulars from the Exhibition Office, 270, Sanchiehall-street, Glasgow.

Fatality.—An Accident occurred at Messrs. Moore & Co.'s Blantyreferme Colliery, Uddingston, on Friday last, resulting in the death of a roadsman named Bellingham.

A runaway hutch had knocked out a prop supporting an iron girder, which fell, and in its descent split the electric cable running along the wall. Bellingham, anxious to clear the obstruction, made to move the girder, which, however, had become charged, and he was instantly killed.

Digitized by Google

Fulham (London).—The Electricity committee have had under consideration suggestions for increasing the demand for electricity, including (a) the free wiring of consumers' premises, and (b) the introduction of metal filament lamps for outside shop lighting at fixed annual charges.

At present there are about 22,000 houses in the borough, but only about 3,000 consumers (including flats) connected to the mains. The suggestion is that the Council should agree to wire for approximately six lights per house or flat, and supply the necessary plain fittings (free of charge), current being supplied through prepayment meters. The wiring would be done by local contractors at schedule rates according to specification. The system of wiring to be adopted would depend largely on circumstances. When surface wiring is unavoidable, the engineer (Mr. A. J. Fuller) advises the adoption of the "Stannos" principle of metal sheathed wiring as being a safe, neat and reliable method. The estimated capital cost of wiring and supplying fittings for six lights, including a transformer, is £3. 3s. per consumer. The committee think that only when the landlord accepts responsibility for all renewals (other than those necessitated by ordinary wear and tear) can the supply of the requisite lamps be included in the scheme, and, failing an undertaking by the landlord, the tenants will be required to provide their own lamps. Where this undertaking is obtained, and after allowing for repayment of principal and interest (extended over 10 years), and providing for renewals of lamps and repairs, the committee are of opinion that the basis of charge may safely be fixed at 5½d. per unit, but where the owner declines to give the undertaking, and the provision and renewal of lamps is not included in the scheme, the charge should be 5d. per unit. It has been ascertained, as a result of preliminary circular and canvas in four streets, that about 112 new consumers may be expected to at once adopt the electric light if this system is introduced.

The Council adopted the committee's recommendation to provide for wiring 500 houses at a total estimated expenditure of £2,000.

The committee have also reported with regard to the proposed introduction of a less powerful outside shop lamp at a fixed annual charge according to candle-power, that for all practical purposes this would be an extension of the present arc lamp rental scheme, and would supply the demand which is said to exist for a less powerful illuminant at a lower fixed charge. The suggestion is that the Council should arrange to supply fix, maintain, clean and renew a suitable outside lantern with 13 in. reflector globe and bracket for fixing to shop facia (the customer providing his own wiring up to the bracket), the lighting being by metal filament lamps of either 100, 200, 300 or 400 c.p., at following fixed charges: (*a*) A fixed charge of £1. 3s. per lamp installed, irrespective of candle-power, to be paid on lamp being fixed: (*b*) a quarterly payment in advance, according to power of lamp installed, as follows: 100 c.p. size, two winter quarters at 15s., £1. 10s., two summer quarters at 5s. 6d., 11s., annual inclusive charge, £2. 1s.; 200 c.p., size, £2, £1. 12s., and £3. 12s.; 300 c.p. size, £3, £2. 2s., and £5. 2s.; 400 c.p. size, £4, £2. 12s., and £6. 12s. (The above charges include current for 870 hours at 3½d. per unit, less 2½ per cent. discount, one new lamp per annum, 7s. per lamp per annum for cleaning, repairing, &c., and 2s. per lamp per annum for sundries.) The present form of arc lamp rental agreement is to be adapted to apply to these lamps, and it has also been arranged that all current supplied in excess of 870 hours per annum be charged as follows: 100 c.p. lamps ½d. per hour, 200 1d., 300 1½d., 400 1½d.

German East Africa.—A hydro-electric generating station with a capacity of 52,500 kw. is to be established at Pangani Falls for the production of fertilisers from atmospheric nitrogen.

Hastings.—Existing gas lamps in streets in which electricity supply mains are laid are to be converted to electric lamps. The gas lamps affected number about 250 and £600 has been provided for carrying out the work of conversion.

Ipswich.—The salary of the electrical engineer and manager of the electricity department (Mr. F. Ayton) has been increased from £500 to £600 a year.

The Rural Electricity Supply Co. have been informed, in regard to the proposal to supply electricity in bulk in Pakefield, that the Council can only supply to a company authorised to supply energy, and they would be prepared to supply a company possessing such powers with current in bulk delivered at an agreed point at the borough boundary at 3d. per unit

Light Railways.—Application is being made to the Light Railway Commissioners for an order to amend the Llanelly and District Light Railways Order, 1907, by reviving certain powers and extending the time for the construction of certain light railways. Objections to the Secretary of the Light Railway Commission.

Limerick.—At a recent meeting of the Corporation it was decided to call in a consulting engineer to report on the plant and the working of the municipal electricity undertaking.

Middlesbrough.—The borough electrical engineer (Mr. H. M. Taylor) has presented his report for the year ended March 31.

Mr. Taylor states that it is the second year's trading under the agreement with the Power Co., and the figures show a substantial improvement on the previous year, in spite of bad trade and high coal prices. The gross revenue shows an increase of £1,271 for an increase in generating and distribution costs of £4,820. Included in these costs is £1,436 for repairs and maintenance to buildings, plant, cables, &c. There is an item of £1,392 (0·19d. per unit) for rents, rates and taxes, an increase of £133. The total costs stand at 1·22d. per unit sold, against 1·26d. The gross profit is £8,406, against £7,617. The profit is £1,301, against £1,277, although there was an increase of £765 in capital charges. The number of consumers has increased by 144, or nearly 15 per cent., and the number of equivalent 30 watt lamps by 11,911, or 11 per cent. The increase in the number of consumers is the greatest which they have had in any year since the undertaking was started.

Newcastle-on-Tyne.—It was recently reported to the Tramways committee that there was a profit of £15,136 on the past year's working of the tramways, against £7,558 in 1908-9.

The traffic income was £272 less, but for electric lighting there was a slight increase (£5,570 against £5,446), and rents also showed a slight increase. Total income was 203,948. 15s. 3d., against £204,123. 1s. 6d. Expenses had been brought from £122,609 in the previous year to £117,593. Traffic expenses were £58,286. 15s.9d., against £56,912.18s.2d. and general expenses £19,318, against £21,272. Repairs and maintenance was £23,751, against £27,924. In permanent way charges there was a saving of £2,000. Power expenses came to £14,563, against £14,947. On the lighting branch they had spent £1,673, against £1,533. The gross profit was £86,355, against £81,513. 6s. 10d. £32,231. 9s. 11d. was required for interest, rents,compensation to electric supply company, and contributions to superannuation fund came to £2,504. 8s. 8d., and income tax £700. 5s. 9d. They had to pay £36, 835. 1s. 6d. as sinking fund and £1,537. 18s. to the Corporation towards liquidating the debt due on old horse cars. There was left a net profit of £15,136. 5s. 9d. to be carried to reserve and renewals account.

Peterhead.—The Council have granted permission to Messrs. Jas. Simpson & Son to lay an underground cable between their works and the new Post Office buildings, for supplying the latter with electricity.

Provisional Order Revocation.—The Board of Trade have revoked the Bromley Rural District Electric Lighting Order, 1903, as from May 7.

Railway Working Agreement.—The working agreement between the London & South-Western Railway and the Great Western Railway Companies, foreshadowed at the last meetings of shareholders of these great undertakings has become an accomplished fact, and it is anticipated that the public, and also traders, will considerably benefit by the new arrangements now being formulated by the companies.

Rochdale.—The total receipts of the electricity department for the year ended March 31 were £22,085.

Total expenses were £9,579. After paying interest (£2,652), sinking fund instalments, &c. (3,652), and other charges the balance (£5,171) was carried forward, against £4,830 in 1909. 4,012,994 units were generated; 2,124,487 units were supplied for traction and 1,420,852 sold to private consumers. The total maximum supply demand was 1,415 kw. for traction and 827 kw. for lighting.

The borough electrical and tramways electrical engineer (Mr. C. C. Atchison) states that the increase in the units sold is practically all due to electricity supplied for power, and this, together with more satisfactory working of the plant, accounts for about half the saving in total costs, the other half being due to reduced prices for coal, the net result being that the department turned out a larger number of units than during the previous year at a less total cost. The reduced charges for lighting and power were in operation for the full period, and the estimated reduction of income (£700) was borne out when the reduction made in the power schedule is taken into account. The tramways item, however, of £250 has been materially exceeded, amounting to over £350 this year. During 1909 the Electricity committee succeeded in having a resolution passed by the Council that an amount equal to 1 per cent. of the capital expenditure should be charged to revenue account annually for depreciation before showing any surplus. The benefit of this action has been shown this year, when, instead of taking the £4,000 which the committee offered for relief of rates, the Council took £5,000, leaving only £505 to go to reserve. This first instalment for depreciation amounts to £973. The reserve fund stands, with the addition of £505, at £6,763. During the first two and a half years of working £5,543 was obtained from the rates, but since then the department has succeeded in producing a net surplus each year, out of which it has to date assisted the rates by a total of £17,350. As the surplus, plus depreciation, amounts to over 6 per cent. for 1909-10, there is a possibility that the committee may reduce the prices charged, but coal is likely to increase in price, and, with all additional power tending to reduce the average income per unit, the committee may not be disposed to cut down its possible surplus.

Rotherham.—Extensions of electric supply mains are to be made at an estimated cost of £620.

South Africa.—The Transvaal Commission who have recently been considering the subject state in their report that they approve of the establishment of large power generating concerns under effective control.

The Commission are of opinion that the gold industry will benefit considerably, that the coal industry will not on the whole be prejudicially affected, and will probably benefit to a large extent ultimately, that the Central and South African Railways will benefit from the general indus-

Digitized by Google

trial expansion, and that the agricultural industry should benefit for the same reason.

The Government bill for regulating the supply and use of electrical energy, which was read a second time in the Transvaal Legislative Assembly on April 13, proposes the formation of a Board to be called the Power Undertakings Board, who will inquire into every application for a supply of power and grant licences to suppliers of power. The bill further provides that power supply companies must state in their applications for licences the minimum amount of power they will be willing to supply to one purchaser, their proposed area of supply, &c. The licence is to state that every applicant for power within the area must be supplied, and it will contain a schedule of prices, subject to revision after 10 years and each succeeding five years, that profits are to be divided in the proportions of 75 per cent. to the licensee and 25 per cent. to the consumers. Certain mine owners' stations, from which it is not proposed to supply outside consumers, are excluded from the scope of the bill. The maximum period for licences is 37 years. The bill as introduced will enable the Victoria Falls Power Co. to supply in the Johannesburg municipal area, but Johannesburg Corporation are seeking to get the bill amended so as to prohibit companies from supplying in the municipal area without the Council's consent, except for operations directly connected with mining.

It is stated that the Victoria Falls & Transvaal Power Co. are about to proceed with the construction of the power station at Vereeniging for supplying electric power to the mines of the Western Rand, and negotiations for the starting of industrial undertakings in the vicinity of the works are taking place.

Southampton.—The tramcar sheds at Shirley depot are to be extended at a cost of £127.

The tramways manager (Mr. H. F. Street) reports that the "Barber" radial axle truck has been tried, and its behaviour round curves exceeds his expectations. He has every reason to hope that this truck will be a vast improvement on anything that has been put on the market in recent years. Others were being made suitable for short car bodies, and he hoped to be soon in a position to advise the purchase of one of these.

The Corporation have agreed to enter into a contract for the electric lighting of certain lamps in the main road of Swaythling.

Spain.—An application has been lodged with the Public Works Department by the Compañia Madrilaña de Urbanizacion for a concession for constructing and working a combined steam and electric railway in the vicinity of Madrid.

Torquay.—The Board of Trade have intimated that they will not renew the licence (which expires on Oct. 31) for the Tramway Company surface contact system of tramways. It is probable that the overhead system will be ready for substitution by that date.

Wireless Telegraphy Notes.—Under the provisions of the International Radio-Telegraphic Convention of Berlin, as from May 15 all French wireless telegraph stations will be open to receive home and international communications for or from ships at sea. The following stations in France are open day and night: Boulogne, Ushant, Porquerolles, S. Marie de la Mer (Marseilles), Fort de l'Eau (Algiers), Ajaccio (Corsica), Brest, Cherbourg, Dunkirque, Lorient and Rochefort, which, although naval stations, will receive public messages only from 7 a.m. until 10 p.m. Boulogne is a specially equipped station, with apparatus for determining the position of ships at sea. The rates for messages transmitted to ships at sea have been fixed at 40c. a word, except in the Mediterranean stations, whence messages for vessels plying regularly between France, Corsica, Algeria and Tunis are accepted at 15c. a word, and from vessels at sea to those stations at 10c. a word.

We are advised from America that a Wireless Corporation has been formed (the Continental Wireless Telephone & Telegraph Co.) to establish commercial coast-to-coast wireless transmission. The existing undertakings which have mutualised their interests are the Collins, the Clark, the Pacific and the Massie Wireless Telegraph Companies. Mr. A. F. Collins, who is described in the document sent us as "the inventor of the wireless telephone," is a director; Mr. F. T. Davis is president, Mr. Walter W. Massie is vice-president, and Mr. F. E. Clark is general manager. The company is stated to be capitalised at $5,000,000. It will operate from Newark, N.J.

Wireless Telephony.—It is announced by "Le Journal" (Paris) that within a few weeks three of the principal French warships will be provided with wireless telephone equipments.

Wakefield.—An inquiry was held here last week into the application of the Council for sanction to borrow £7,150 for extensions of the electricity undertaking.

The town clerk (Mr. W. W. GREENHALGH) explained that the money was required for additional plant to meet the increasing demand for electrical energy for lighting and power. The number of consumers was increasing steadily

The inspector (Mr. H. Ross HOOPER) pointed out that the L.G. Board were not likely to sanction any further loan until the deficit had been cleared off.

The TOWN CLERK replied that that was due to the new assessment of the works, the abnormal advance in the price of coal last year and the economy in consumption by consumers owing to the extended use of metal filament lamps.

Evidence was given by the electrical engineer (Mr. H. A. Nevill), but the Inspector desired further information with regard to the allocation of accounts, &c., and the inquiry was adjourned.

West Ham.—The Electricity committee report that the whole of the points between the Port of London Authority and the Corporation as to the supply of electric current have been settled, and the consent of Woolwich Council or the approval of the Board of Trade is alone necessary. The principal question outstanding is the payment to be made to Woolwich for their consent.

Wimbledon.—An inquiry was held last week into the application of the Council for sanction to borrow £5,800 for extensions of the electricity undertaking.

Woolwich.—London County Council have agreed to permit electric cables being laid through the new Woolwich subway for 21 years for supplying electricity to North Woolwich, in consideration of the payment of £50 per annum.

The Electricity committee have decided that the word "power" includes all purposes to which electrical energy may be applied other than its use either directly or indirectly for lighting. Consumers who use motors for driving gas compressing plant are to be charged 4d. per unit.

Workhouse Lighting.—Aberdeen Parish Council have asked the Poorhouse committee to report as to whether any saving would be effected by taking the supply of electricity for the poorhouse from the Corporation.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., **post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.**

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding **that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable** and of little value for **Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.**

TENDERS INVITED.

BARNES Urban District Council invite tenders for supply of 4,000 yds. of 0.25 0.25 1.25 sq. in. triple concentric cable, paper insulated, lead sheathed and jute served, suitable for a working pressure of 660 volts, manufactured in strict accordance with the British Engineering Standards committee's specifications. Tenders to the Clerk to the Council, High-street, Mortlake, by noon Tuesday, June 14. See also an advertisement.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

NEWPORT (Mon.) Electricity committee invite tenders for supply and erection of two 400 kw. motor-generators, three-phase to d.c.; one 600 kw. motor-generator, three-phase to single-phase; and one 'bus-bar three-wire booster. Specifications, general conditions and form of tender from the borough electrical engineer and tramways manager, Mr. H. Collings Bishop, Town Hall, Newport, Mon. Tenders to the Town Clerk by first post May 31.

COVENTRY Electricity committee invite tenders for supply, delivery and erection of a 1,250 kw. turbo-alternator, complete with surface-condensing plant, &c., four water-tube boilers (straight

Digitized by Google

tube type) and two fuel economisers. Specification, general conditions and forms of tender from the engineer and manager, Mr. Geo. Tough, and tenders to the Town Clerk, Hay-lane, Coventry, by first post May 30.

SOUTHAMPTON Corporation invite tenders for supply of a 1,000 kw. steam generator, boiler, alternator and motor alternator. Particulars, specifications and forms of tender from the borough electrical engineer, Mr. H. F. Street, electricity works, Western Shore, Southampton. Tenders to the town clerk, Mr. R. R. Linthorne, Municipal Offices, Southampton, by May 24.

CROYDON Corporation want tenders by 11 a.m. May 26 for lighting the two isolation pavilions and additions to the administrative block of the Borough Hospital, Waddon. Specification, &c., from the Borough Engineer.

DARLINGTON Electricity committee want tenders by May 25 for a cooling tower, electrically-driven centrifugal and air pumps and a boiler feed pump. Specifications, &c., from the Borough Electrical Engineer.

The LIVERPOOL Overhead Railway Co. require tenders by 10 a.m. June 7 for 12 months' supply of electrical fittings, insulating tapes, iron and steel, ironmongery, oil and grease, packings, &c. Forms of tender, &c., from 31, James-street, Liverpool.

BATLEY Corporation require tenders by noon June 1 for a lighting and traction switchboard for the electricity works Specifications, &c., from the Borough Electrical Engineer.

BERMONDSEY (London) Council require tenders by 10 a.m. May 27 for Midland and Scotch coal for the electricity works. Forms of tender from the Town Clerk.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zinc for batteries. Local representation is necessary.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

Tenders will be received (up to 11 a.m. June 6) at the Royal Arsenals, SPEZIA and NAPLES, for supply to the Italian Naval Authorities of electric lamps and lamp stands in two separate lots. The total estimated value of the contract is placed at 32,009 lire (about £1,280), and a deposit of 1,880 lire (about £74) will be required to qualify tenders for lot 1, and a deposit of 1,330 lire (about £53) for lot 2. Only manufacturers of electric lamps will be allowed to tender. Applications for certificates of competency to the Director of Naval Construction at Spezia, Naples, Venice or Taranto not later than May 21. Copies of the specifications, conditions of tender, &c., may be seen by British firms at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Tenders have been received by Newport (Mon.) Corporation for a turbo-alternator from Willans & Robinson, General Electric Co., Dick, Kerr & Co., C. A. Parsons & Co., the British Thomson-Houston Co. (Jas. Howden & Co.) and the British Westinghouse Co. The tender for 1,500 kw. turbo-alternator and condenser by Willans & Robinson and General Electric Co. has been accepted.

Bootle Council have accepted the following tenders:—

Chloride Electrical Storage Co., automatic reversible traction booster (£424); Whipp & Bourne, automatic reversible current breakers and traction feeder breakers (£141), and shunt regulating resistances and switches (£52); Jas. Scott (Ltd.), rewinding balancers (£79) and circulating pump (£120); Bruce Peebles & Co., two dynamos (£295); Kelvin & James White, switchboard instruments (£54).

Woolwich Electricity committee have accepted the tender of Ferranti Limited for the annual supply of a.c. meters for use in Eltham. The British Thomson-Houston Co. have submitted a new type of meter which the committee desire to test under actual working conditions.

Richmond Council have accepted the tender of James Simpson & Co. at £115. 10s. for an electrically-driven pumping plant for the Petersham Well.

Yarmouth Council have accepted the tender of John Baker & Co. for 30 steel tramway tyres at £1. 14s. 6d. each.

Chichester City Council have accepted the tender of the local electric light company for wiring the new schools.

Malvern Council have accepted the tender of the British Thomson-Houston Co. for meters for five years.

BUSINESS NOTICE.

For the convenience of their customers in the south-west London district, the Hart Accumulator Co. have opened a branch at 36, Victoria-street, Westminster, S.W., with Mr. W. Howard Tasker as their representative. The branch is in telephonic communication with the company's works at Stratford.

Plant for Sale.—A 240 kw. Howden-Crompton direct-coupled generating set is advertised for sale in another column. Particulars from Messrs. W. E. Moulsdale & Co., 24, Chapel-street, Liverpool.

Patents Development.—The proprietors of the following patents desire to enter into arrangements by way of licence and otherwise for exploiting and developing the same in this country:—

No. 17,601/1901, for "Improvements in apparatus and devices for controlling electric currents"; No. 15,243/1903, for "Improvements in means for automatically regulating electric currents generated by dynamos"; No. 16,962/1902, for "Improvements in electrical switches or cut-outs"; No. 17,314/1905, for "Improvements in automatic regulators or rheostats for electric currents." Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

Patent No. 10,187/05, for "Improvements in electric couplings." Applications to Messrs. G. F. Redfern & Co., 15, South-street, Finsbury London, E.C.

CATALOGUES, &c.

MATERIALS FOR TELEGRAPH AND TELEPHONE LINES.—Messrs. Siemens Bros. & Co., Caxton House, Westminster, S.W., have forwarded a copy of the March issue of their pamphlet No. 11, "Iron Poles, Insulators and Materials for Telegraph and Telephone Lines." This is one of the largest and most complete publications of its kind, comprising 124 pages, containing descriptions and illustrations of line materials and appliances to meet requirements in all countries. The pamphlet has been divided into six sections, dealing respectively with Siemens iron poles, insulators and stalks, brackets, arms and fittings, stay tighteners, tools and bolts and screws.

The introduction to the iron pole section is of special interest, in that it traces the evolution of the various types of Siemens poles which are listed, from the tubular iron pole, with buckled plate, which was originally designed and patented in 1863 by Sir William Siemens, down to the present time. Interesting particulars of a great variety of poles are set out. The insulator and stalk section contains, besides examples of telegraph and telephone insulators, which have been designed to meet the requirements of practically every Government and telegraph company, a large selection of porcelain reels and knobs, which find useful application in all branches of the electrical industry. The section dealing with brackets, arms and fittings contains every conceivable form of device to meet the existing practice of securing insulators and stalks. The remaining sections give all the accessories and tools that are required for the erection of land lines.

The pamphlet is coded throughout, and is provided with a comprehensive system of cross references, so as to facilitate the drawing up of specifications and schedules for lines and the necessary materials required.

"Installation News."—The May issue of "Installation News" contains an article on "Conduit Clauses in Specifications," in which some useful information is given. A hint on connected-up motors should also interest wiremen.

BANKRUPTCIES, LIQUIDATIONS, &c.

The examination took place at Bristol last week of Robert Edward Joy, electrical engineer, 143, Cheltenham-road, Bristol.

Gross liabilities £649. 5s. 6d., and unsecured debts £602. 10s. 10d.; net assets £87. 18s. 6d., deficiency £514. 12s. 4d. Debtor began business in 1907 without capital. He admitted that he had contracted all his present indebtedness with a knowledge of his insolvency, of which he was aware about three years ago. He had made no net profit during the last two or three years. Claims are to be sent to Mr. F. I. Clark, 26, Baldwin-street, Bristol, by June 3.

An application for the discharge of Ernest Roberts (trading as Roberts Bros.), electrical engineer, 21, North Parade, Bradford, will be heard on June 21 at the County Court House, Manor-row, Bradford.

The Automobile Electric Lighting Synd. (Ltd.) and the Polkey Automobile Electric Lighting Synd. (Ltd.) are being wound up voluntarily, and meetings of creditors will be held at Mr. A. R. Lancaster's, Queen's College, Birmingham, on May 24.

The Lepel Wireless Synd. (Ltd.) is being wound up voluntarily and Baron von Lepel and Mr. A. Holt have been appointed liquidators.

A meeting will be held on June 27 at 79-81, Queen-street, London, E.C., to receive an account of the winding up of the Electric Tramways Construction & Maintenance Co. (Ltd.)

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

March 8, 1910.

5,735 Docking. Pendants for electric lamps.*
5,747 Adams. Insulating cups for telegraph, telephone and other electric wires.
5,766 Hirst & Brook. Time-limit overload devices for actuating the no-volt release devices of circuit-breakers and motor starters.
5,801 Adams Mfg. Co. (Cutler Hammer Mfg. Co., U.S.) Electromagnetically actuated electric switches.*
5,818 Patterson. Electric safety lamps for use in mines or other like places.
5,822 Davidson. Thermopiles or thermo-electric couples.*
5,823 Fanning & Nellis. Electric switching mechanism.*
5,835 Neudorffer. Insulating wall boxes for electric apparatus.*

March 9, 1910.

5,896 Taylor. Obtaining continuous currents from alternating-current circuits.
5,917 Siemens & Halske Akt.-Ges. Rectifier for high-tension alternating currents. (Date applied for, 28/5/09.)*†
5,926 Bennett. Sockets of incandescent electric lamps.
5,934 Johnson. (Chemische Fabrik Griesheim Elektron, Germany) Production and maintenance of long electric arcs. (Addition to No. 11,060/09.)

March 10, 1910.

5,965 Jandus Arc Lamp & Electric Co., Jones & Castell-Evans. Arc lamps.
5,985 Smith, Green & Glover. Alternating-current induction motors.*
6,035 Petersson. Charging electric resistance furnaces. (Date applied for, 2/6/09.)*†
6,065 Ely & Foster Arc Lamp & Engineering Co. Electric water heaters.

March 11, 1910.

6,124 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke G.m.b.H., Germany.) Alternating-current commutator electric motors.*
6,125 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke G.m.b.H., Germany.) Regulation of electric frequency converters.*
6,132 Brooker & Hooper. Locking device for electric lamp-holders.
6,160 Adams Mfg. Co. (Cutler Hammer Mfg. Co., U.S.) Electric switches.*

March 12, 1910.

6,190 Bishop. Locking nuts on insulator attachments of telegraph poles and for other like uses.
6,191 Ewart. Electric lamp-holders and lamp caps for same.
6,207 Bastian. Electrically heated appliances or apparatus.
6,212 Meguin & Co. A.-G. Electromagnetic apparatus. (Date applied for, 12/3/09.)*†
6,256 Landi. Electrical speed indicator.*
6,272 Allmanna Svenska Elektriska Actiebolaget. Single-phase commutator machines. (Date applied for, 2/8/09.)*†
6,292 B.T.-H. Co. & Wedmore. Protective or indicating devices.

March 14, 1910.

6,312 Hall. Automatic generation of electricity for motor cars.
6,353 Adams Mfg. Co. (Cutler Hammer Mfg. Co., U.S.) Electric switches.*
6,397 Wolfram Lampen Akt.-Ges. Support for incandescent filaments. (Date applied for, 13/3/09.)*†
6,402 Akt.-Ges. Brown, Boveri & Cie. Driving of single-phase motors. (Date applied for, 18/11/09.)*†
6,403 Akt.-Ges. Brown, Boveri & Cie. Driving of electric rail vehicles. (Date applied for, 1/4/09.)*†

March 15, 1910.

6,431 Hall. Terminal ends of electric cables.
6,432 Hall. Electric generators for motor cars.
6,433 Hall. Electric wiring for supplying current for motor cars (conduit system).
6,526 Capitaine. Incandescent lamps. (Date applied for, 9/12/09.)*†
6,531 Sunderland & Pillinger. Electric control of engines, dynamos and batteries.
6,535 Barnard & Edwards. Controlling devices for electric motors.*
6,536 Bleckly. Multiple arc lamps.*
6,553 Jevons & Green. Electric welding.

March 16, 1910.

6,589 Staniar & Clegg. Supporting electric wiring conduits in position.
6,594 Turnbull. Balancing apparatus for three-wire and the like electrical-distributing systems.*
6,595 Waterhouse. Electric light pendant fittings.*
6,596 & 6,597 Schott & Gen. Electrolytic apparatus having a liquid annular anode. (Addition to No. 14,288/09. Date applied for, 30/3/09.)*†
6,624 Zweigbergk. Dynamo-electric machines.
6,633 Field & Ferranti. Circuit-breakers and the like.
6,634 Loring. Dynamo-electric machines of the homopolar type.
6,653 Bosch. Magneto-electric ignition machines. (Date applied for, 18/5/09.)*†
6,654 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges., Germany.) Automatic telephone exchanges.*
6,658 Salzer. Holders for the filaments of incandescent electric lamps. (Date applied for, 19/3/09.)*†
6,667 B.T.-H. Co. & D'Arcy. Electric energy meters. (Addition to No. 6,565/09. Date applied for, 20/9/09.) Comprised in No. 6,565, dated 20/9/09*
6,668 B.T.-H. Co. & Wedmore. Protective devices for electrical transmission and distribution systems. (Date applied for, 18/10/09. Comprised in No. 17,031, dated 18/10/09.)*

March 17, 1910.

6,681 Dixon. Electric trolley heads.
6,704 Charlton. Systems of electric wiring and apparatus relating thereto.
6,706 Marshall. Machines for the manufacture of flexible metallic tubes or for armouring insulated electric and other cables.*
6,719 Bridge. Make-and-break contact devices for electric circuits.*
6,743 Boot & Tarrant. Electrically-operated signalling for railways or tramways.
6,746 Gatinaud. Electric accumulators.*
6,768 Stora Kopparbergs Bergslags Aktiebolag. Electric furnaces and the method of charging the same. (Date applied for, 19/3/09.)*†
6,782 Compagnie four la Fabrication des Compteurs et Materials d'Usines a Gaz. Recording galvanometers and other instruments operating with a very small turning moment. (Date applied for, 15/5/09.)*†
6,791 B.T.-H. Co. (A.E.G., Germany.) Regulating valves and the like.
6,792 B.T.-H. Co. & Wedmore. Electric circuit interrupting devices and the like.

March 18, 1910.

6,814 Fuller, Moore & Fuller. Electric road lamps.
6,825 Neave. Controllers for electric motors.*
6,865 Pizzuti & Ferrari. Shortening electric waves.*
6,867 Adams Mfg. Co. (Cutler Hammer Mfg. Co., U.S.) Motor controllers.*
6,868 Konecke. Three-phase current arc lamp. (Date applied for, 19/3/09.)*†
6,870 Anger. (Walter Everett Anger, U.S.) Sparking plugs.
6,871 Williams-Ellis. Calculating devices for electrical quantities.
6,875 Siemens & Halske Akt.-Ges. Semi-automatic telephone exchanges. (Date applied for, 18/3/09.)*†
6,876 Damaskinos. Telegraphic relays.
6,881 Tucker. Current collectors for overhead electrical tramways and light railways.
6,894 B.T.-H. Co. (G.E. Co., U.S.) Electric measuring instruments.
6,895 Petersen & Sem. System for use in long-distance telephony. (Date applied for 25/3/09.)*†

SPECIFICATIONS PUBLISHED.

1909 Specifications.

5,418 B.T.-H. Co. (G.E. Co., U.S.) Controlling electric circuits.
5,427 Addison. Switch for use with electric transformers.
5,459 McClelland & Ferranti Limited. Maximum current indicator for electricity.
5,685 Hughes. (Murray.) Wireless electric fog signalling apparatus.
5,955 Twigg. Electric sparking plugs.
6,049 Hope. Metal casings of electric fuse boards.
6,111 Ghadiali. Totally de-energising overhead dangerous electrical wires the moment they snap.
6,477 Lancashire Dynamo & Motor Co. & Stelling. Rotors of alternating-current dynamo-electric machines.
6,770 Twaites. Electric accumulator.
6,936 Westinghouse Metal Filament Lamp Co. (Lederer.) Metal filaments for incandescent electric lamps.
6,956 Siemens Bros. Dynamo Works & Kloss. Starting of electric induction alternate-current motors.
7,106 Moser. Synchronous alternating-current machines with automatic regulation of the tension or pressure. (Addition to No. 6,103/09.)
7,410 De Daillens & Joris. Portable electrically-driven drilling machines.
7,471 Jaburg. Arc lamps. (Date applied for, 28/3/09.)
8,025 Baker. Electric switches.
8,077 Sedgwick. Electric lamp holders.
8,345 Mosep. Self-regulating alternating-current additional machine or booster. (Date applied for, 11/7/08.)
8,351 B.T.-H. Co. (G.E. Co., U.S.) Electric incandescent lamp-making machines.
8,582 Marconi & Marconi's Wireless Telegraph Co. Transmitters for wireless telegraphy. (Addition to No. 20,119/07.)
9,035 Higgins & Sheridan. Electric signalling systems for railways.
9,094 Kennedy-McGregor. Electric circuit closers.
9,194 Cottier. Locking electric incandescent lamps to their holders.
9,427 Monasch. Means for producing phase displaced electromagnetic oscillations. (Date applied for, 21/4/08.)
9,693 Joel. Portable electric lamps. (Addition to No. 11,106/08.)
9,706 Hirst & Krause. Electric fan motors.
9,996 Brock. Joint for tramway or railway rails and the like.
10,175 Von Ugrimoff. Electrical sliding contacts.
10,348 Brampton & Osborne. Conduit fittings. (Addition to No. 8,601/09.)
10,594 B.T.-H. Co. (G.E. Co., U.S.) Protective devices for electric distribution systems.
10,607 Key Engineering Co. & Andrews. Conduits for electric conductors.
10,663 Brazil & Cooch. Protective devices for alternating-current systems. (Cognate Application, 22,551/09.)
10,739 Pugh & Bull. Junction fittings of metallic conduits for electric conductors. (Post dated 6/5/09.)
11,154 Patterson. Galvanic batteries. (Date applied for, 26/4/09.)
11,326 Eccles & Hadfield. Trolley retrievers for electric cars.
11,765 Lecler. Openwork or armatures for reinforced concrete structures. (Date applied for, 18/5/08.)
11,842 Cowper-Coles. Regenerators for use in the electro-zincing process.
12,286 Hall. Magneto-electric ignition apparatus for use with the ignition systems of internal-combustion engines.
12,335 MacDiarmid & Bates. Electric switches.
12,507 Ruthenburg. Electrodes for electric furnaces.
12,709 Electrolytic Alkali Co., Connor & Stubbs. Electrodes for electrolytic purposes.
12,744 W. T. Henley's Telegraph Works Co. & Nichols. Electrical fuse carriers.
12,774 McLean. Brush-holders for dynamo-electric machines.
12,917 Mavor & Mavor & Coulson. Controlling the speed of bodies driven by alternating-current electric motors.
12,970 Le Blanc. Systems for electrically controlling searchlights from a remote point.
13,010 Johnson. Electrical torsiometer.
13,041 Siemens Bros. Dynamo Works & Kloss. Suppressing electric currents due to harmonics in the wave-forms of alternating-current dynamo-electric machines.
13,059 Crafton & Johnson & Phillips. Alternating-current generators.
13,129 Monnier. Distributing box for underground cables with multiple electrical conductors. (Date applied for, 6/6/08.)
13,655 B.T.-H. Co. & Richardson. Switchboards for electrical installations.
14,165 Millauro. Arc lamps. (Post dated 25/3/09.)
14,209 Pickford. Telephonic transmitters and the like.
14,244 May. Telephone system.
15,032 Kozesnik. Third rail electric railway systems.
15,317 Prott. Electric motor.
15,389 Hindley, Hindley & Stanford. Electric ignition apparatus for internal combustion engines.
15,421 B.T.-H. Co. & Dawson. Current-collecting devices for dynamo-electric machines.
15,578 Kennedy-McGregor. Electric switches.
15,851 Siemens Bros. & Co. & Ferreira. Electrical mercury switches operated by a vehicle passing along a railway.
16,004 Bluemel, Bluemel, Bluemel & Shill. Electrically-controlled pneumatic dispatch tubes, cash railways and the like. (Addition to No. 3,770/08.)
16,170 Hunt & Sandycroft Foundry Co. Alternating-current dynamo-electric machines.
16,631 Akt.-Ges. Brown, Boveri et Cie. Control of dynamo-electric machinery in electric lighting installations worked with accumulators. (Date applied for, 14/9/08.)
17,137 Foss. Sound intensifiers for telephone mouthpieces and the like.
17,353 Berry. Electrical heating apparatus.
17,450 Fessenden. Wireless signalling. (Date applied for, 8/3/09.)
17,653 Mueller. High-tension magnetos. (Date applied for, 4/8/09.)
17,664 Mueller. Magneto-electric machines. (Date applied for, 25/2/09.)
17,824 Fuller. Electric dry batteries.
17,909 Geiger. Arc lamps.
18,005 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Electric control of clocks.
18,534 Bosch. Multiple distributor for electric ignition apparatus. (Date applied for, 20/7/09.)
18,950 Clement. Telephone exchange system.
19,057 Kelvin & James White, Chetwynd & Clark. Magnetic compasses.
19,111 Friedrich. Regenerating electric accumulators.
19,210 B.T.-H. Co. (G.E. Co., U.S.) Dynamo-electric machines.
19,263 Edwards. (German.) Fusible cut-outs for electrical apparatus.
19,424 Trentmann. Electric lighting devices for life buoys.
20,003 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.) Adjustable transformers for polyphase electric alternating currents.
20,311 Bloxam. (Geb. Siemens & Co.) Arc lamps.
20,413 Dusseris. Electric switching devices for controlling electro-magnetic clutches.
20,656 Bosch. Current distributors for the ignition devices of internal combustion engines. (Date applied for, 7/4/09.)
20,832 Weinert. Carbons for arc lamps.
20,841 Kingsbury. (Western Electric Co.) Selector switch.
20,842 Kingsbury. (Western Electric Co.) Automatic selective switching apparatus.
20,882 Jenkins. Electric hand lamps.
20,922 Justice. (Kunsch & Jaeger Ges.) Photographic recording apparatus for galvanometers, oscillographs and the like.
21,113 Crompton & Co., Macfarlane & Burge. Electrical regenerative control apparatus and systems. (Date applied for, 3/3/09.)
21,222 Skinner. Iron poles for telegraphs, telephones and the like.
21,374 Geb. Siemens & Co. Electrodes for arc lamps. (Date applied for, 5/10/08.)
21,763 Allgemeine Elektricitats Ges. Centrifugal pumps and the like. (Date applied for, 24/9/08.)
22,273 Meszaros, Fawns & McCracken. Metallic filament lamps.
22,385 Howe & Taylor. Electric switches and the like.

22,479 Bosch. Insulation of windings in electrical apparatus. (Date applied for 12/12/08.)
22,768 Christoph & Klein. Arc lamps.
23,177 Isaacson. Magneto-ignition apparatus.
23,863 Schmeltz. Charging electrical accumulators or secondary batteries.
24,185 Siemens & Halske Akt.-Ges. Electric signalling installations. (Date applied for, 21/10/08.)
24,306 Allgemeine Elektricitats Ges. Continuous-current motor generators or transformers. (Date applied for, 22/10/08.)
24,632 Walden. Electrically reset gravity escapement.
24,771 Waterhouse. Combination coupling for electric conductors.
24,812 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Telephone exchanges.
24,892 Brampton & Osborne. Conduit fittings for electrical and other purposes, and the manufacture of same. (Date applied for, 10/4/09.)
25,028 Moloney & Ross. Telephone transmitters.
25,259 Burton. Electric insulators.
25,445 Nordentoft. Electric fuses.
25,733 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.) Electric fuse fittings. (Addition to No. 8,263/09.)
25,883 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Telephone exchanges.
25,962 Siemens Bros & Co. (Siemens & Halske Akt.-Ges.) Electrical mercury switches. (Addition to No. 6,037/05.)
27,033 Milton. Generating alternating currents. (Date applied for, 30/1/09.)
27,103 Bosch. Carbon holders in magneto-ignition apparatus, current distributors or the like. (Date applied for, 27/7/09.)
27,245 Fried. Krupp Akt.-Ges. Regulating devices for direct-current dynamos. (Date applied for, 18/3/09.)
27,446 Rawlings. Tumbler switches. (Date applied for, 7/1/09.)
27,472 Falk, Stadelmann & Co. & Charles. Means for holding globes or shades in the galleries of electric light, gas and other fittings.
27,560 Timar. Electromagnetic igniting device for arc lamps.
27,757 Navarro. Supports or insulators for carrying electric conductors or cables.
28,184 Sterling Telephone & Electric Co. (Telephon Fabrik Akt.-Ges. vorm. J. Berliner.) Electric switches.
28,363 Siemens & Halske Akt.-Ges. Telephone exchanges. (Date applied for, 5/12/08.)
28,362 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Telephone exchanges.
28,825 Siemens & Halske Akt.-Ges. Telephone exchanges. (Date applied for 12/12/08.)
29,491 Chemische Fabrik Griesheim-Elektron. Manufacture of anhydrous caustic soda. (Date applied for, 23/12/08.)

COMPANIES' MEETINGS AND REPORTS.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT.—The annual report states that business is satisfactory, but prices have been affected by keen competition. Producing costs have been reduced owing to lower prices of raw materials and to improved methods of manufacture. The value of the work executed by the machinery department between July 1, 1909, and March 31, 1910, was 11,000,000 marks (£550,000) in excess of that for the previous corresponding period, and establishes a record. Electrical locomotives, both for passenger and goods transport, are in course of construction, and are of various sizes up to 1,800 H.P. A system of power transmission for very high voltages has been perfected, and a new factory for this work is already partly in use. The turnover in small motors has increased considerably, and this department is being enlarged. The output of the turbine works showed an increase over last year of 50 per cent., and this department now employs over 3,000 workpeople. The cable works at Oberspree were well employed, and the output showed an increase of 6,000,000 marks. The cable works have to meet the demand for higher voltages, and 30,000 volts may now be considered normal, but by no means indicates the probable limit. As several departments are badly situated for enlargements, a new factory is in course of erection, and will be completed about the end of the year. The incandescent lamp works show an increase in output owing to the growing demand for metal filament lamps, though there is still a steady demand for carbon filament lamps. The total turnover of the undertaking for the first three quarters of the current year has declined slightly compared with last year owing to a decrease in orders from the Berlin Electricity Works, but orders on the books at present are 18,00,000 marks in excess of those at this time last year. The land at Henningsdorf has been laid out for new works.

ANGLO-ARGENTINE TRAMWAYS CO. (LTD.)—The gross receipts during 1909 were £1,938,887. 13s. and the working expenses £1,207,222. 6s. 2d., leaving £731,665. 6s. 10d. Adding £12,839 brought forward, £24,099 interest, &c., the total was £768,603. 18s. 8d. After paying the annuity to "City Company" (£70,660) and interest on debenture stock and preference dividends, and the 6 per cent. interim dividend on ordinary shares, the balance was £80,972. 17s. 3d., and the directors recommend a final dividend on the ordinary shares at the rate of 6 per cent. (less tax), which will absorb £70,625, leaving £10,347. 17s. 3d. to be carried forward. The total length of the combined tramways is 332 miles of single track. The great development of traffic makes some form of relief necessary. Applications were made last year by Buenos Ayres Western Railway Co. for a concession for an underground line from Plaza Once to Plaza Mayo and the Port, and by other parties for concessions for the construction of other underground railways. In these circumstances the company considered it advisable to apply for a concession for the construction of certain subways. The National Government granted a concession to the Buenos Ayres and Western Railway and the Municipality granted to the Anglo-Argentine Co. the concession for constructing subways near the surface, and the Western Railway will, therefore, construct their tunnels at such depth as will not interfere with any of the proposed subways. The contract concluded with the Municipality authorises the construction of three lines of an aggregate of over 10 miles to be worked by electric traction in conjunction with the company's existing system. The company is to pay to the Municipality a tax of 6 per cent. of the gross receipts of the subway traffic. No new taxes are to be imposed by the Municipality during the term of the concession. The concession for the whole undertaking of the company, including all lines recently acquired, is fixed at 80 years from March 18, 1910. The directors have arranged to purchase the Metropolitano tramways, which are at present held on lease, and in order to provide funds for the construction of the subways, the purchase of the Metropolitano tramways, &c., the directors ask for power to create and issue £6,000,000 5 per cent. debenture stock, to rank after the existing 4½ per cent. debenture stock, and to increase the second preference share capital by £500,000 and the ordinary share capital by £1,500,000. It is also proposed to increase the dividend on the first and second preference shares respectively from 5 to 5½ per cent.

BARNSLEY & DISTRICT ELECTRIC TRACTION CO. (LTD.)—The total revenue for 1909 amounted to £9,043. 12s. 9d. and expenditure to £7,141. 2s. 5d., leaving a profit of £1,902. 10s. 4d. Adding £196. 4s. 5d. brought forward, the total is £2,098. 14s. 9d. £200 has been placed to depreciation and reserve and £350 to sinking fund for redemption of loans and debenture stock, and after paying the preference dividend for the year (£1,320) the balance (£228. 14s. 9d.) has been carried forward. The net result is £150. 0s. 4d. better than in 1908, although the receipts from traffics and parcels show a decrease of £406. 0s. 8d., due to strikes in the coal trade and bad weather. The expenses show a reduction of £683. 10s. 11d.

CITY OF BIRMINGHAM TRAMWAYS CO. (LTD.)—The directors' report for 1909 states that they have decided to recommend the shareholders to equalise the amount paid on the whole of the ordinary shares by returning £4 per share upon each ordinary share upon which £5 has been paid. This payment will be made out of profits, and will leave a liability of £4 per share on all the ordinary shares. After providing £12,000 for debenture interest and £12,083. 6s. 8d. for preference dividend, the surplus on the past year's working was £38,516. 16s. 9d. Deducting £2,104. 14s. for interim dividend at the rate of 5 per cent. on the ordinary shares for the June half-year, there remains £36,412. 2s. 9d. The directors recommend an ordinary dividend at the rate of 5 per cent. for the last six months and a bonus of 5 per cent. (making 10 per cent. for the year), and the payment of £24,188 (£4 per share in reduction of paid-up capital of £5 per share upon 6,047 ordinary shares), £5,910. 0s. 9d. being transferred to reserve. The traffic receipts, compared with the previous year, show an increase of £3,360. 14s. 5d., and receipts from advertising and interest on investments show an improvement of £4,019. 9s. 11d. A reduction of £4,246. 15s. 7d. has been effected in the cost of maintenance of tramways and payments to local authorities. The price payable by Handsworth Council (£72,174) for the company's Handsworth undertaking has been received. The Council are under obligation to grant a lease of the cable tramway to the company from the date of purchase to June 30, 1911. An agreement has been entered into with the Council for the operation of through services from Birmingham, through Aston, to the terminus of the Perry Barr route in Handsworth, and from Aston, through Handsworth, to West Bromwich, when the cable line is electrified, and the Villa-road line reconstructed and open for traffic. Notice has been received from Yardley Council of its intention not to exercise its option to purchase the electrical plant at the Yardley power station. The company have protested against the charges made by Birmingham Corporation for repairs to permanent way of Bristol-road tramway. The lease of the tramways provides that the decision of the City Surveyor is to be final on all questions or differences that arise under the lease in regard to value, repair and construction. The company applied to the Corporation to appoint an independent person as arbitrator, but the Corporation refused to depart from the terms of the lease. The Corporation has acknowledged the claim made against it for loss of traffic receipts arising out of the delay in completing the reconstruction of the Bristol-road line and £540 has been paid. The working of the company's undertaking by the joint committee continues to show satisfactory results and the arrangement has been further continued.

ELECTRIC SUPPLY CORPN. (LTD.)—At the meeting last week the chairman (Mr. J. Stone) said that in future the company would depend solely on its own earnings, as the final payment under the guarantee had been made. Originally it was estimated that at the expiration of the guarantee the company would be earning 5 per cent. on its shares, but that would not be accomplished for several years, although the table of progress showed a steady advance. Soon after the flotation of the company the electrical supply business was revolutionised by the introduction of metal filament lamps, and that upset their calculations, which were based on the carbon lamp. Their view, that the metal filament lamp was benefiting the company by bringing the light within the means of small consumers, had been verified by the results.

FELTEN & GUILLEAUME-LAHMEYERWERKE, A.G.—The directors' report for 1909 states that all their factories were kept well employed throughout the year, but owing to the general fall in prices of electrical machinery the results were comparatively poor. The gross trading profit was M.13,993,100 (£699,655), compared with M.14,618,900 (£730,945) in 1908, while the net profit was £181,200, against £256,400. The dividend is 6 per cent, against 8 per cent. in 1908.

LEAMINGTON & WARWICK ELECTRICAL CO. (LTD.)—Capital expenditure during 1909 was £798. 1s. 5d. in respect of mains, &c., for supply of electricity in Warwick and other equipment. The accounts show a credit balance of £5,504. 16s. 9d. from the tramways and electricity supply. Deducting expenses (£1,281. 2s. 5d.), interest and provision for renewals, there remains £2,458. 15s. 5d. Adding £282. 16s. 5d. brought forward, the total available for distribution is £2,741. 11s. 10d. The directors recommend a dividend at the rate of 2 per cent. on the ordinary shares. The unsatisfactory weather during the year had an adverse effect on the traffic receipts. The number of installations connected at Dec. 31 was 206 (exclusive of tramway load), and was equivalent to 7,870 8 c.p. lamps, compared with 7,402 8 c.p. lamps in 1908.

MUSSELBURGH & DISTRICT LIGHT & TRACTION CO. (LTD.)—The accounts for 1909 show an available sum (after providing for deben-

Digitized by Google

ture interest and including £131 brought forward) of £3,811. The directors recommend the transfer of £2,000 to reserve and renewals fund and carry forward £1,255. This would permit of a dividend of 2½ per cent. on the preferred shares, and the directors hope this will be paid towards the end of July.

PARA ELECTRIC RAILWAYS & LIGHTING CO. (LTD.)—The chairman (Sir W. Evans-Gordon) stated at the meeting last week that the receipts from the tramways had been better by £17,300 and the receipts from the lighting increased by £3,400. Working expenses of the tramway were £24,300 less and the working expenses of the lighting part were £8,000 less. Since Nov. 30 the working expenses had been further reduced, so that for the four months of the current year, compared with the corresponding period of the previous year, they were well under 50 per cent. for both tramways and lighting. There had been a great improvement of the electric lighting branch, and he thought a further extension was certain to take place in connection with the use of electrically-driven fans and pankahs. Once the people used pankahs they found it impossible to do without them, because they gave such an increased amount of comfort in a country where is was hot all the year round. They had earned enough to enable them to pay a dividend upon the ordinary shares at the rate of 7½ per cent. They were now clear of the arrears of preference dividend, and the directors considered the position so satisfactory that they would be quite justified in paying an interim dividend later on on these shares for the first half of the current year.

REUTER'S TELEGRAM CO. (LTD.)—The directors' report for 1909 states that the balance for distribution amounts to £4,992. 6s. 9d., including £693. 18s. 10d. brought forward. An interim dividend of 2½ per cent. has been paid, and the directors now declare a dividend of 4s. per share (2½ per cent.), making a total distribution (tax free) of 5 per cent. for the year. £256. 14s. 9d. is carried forward.

SAO PAULO TRAMWAY, LIGHT & POWER CO. (LTD.)—The gross earnings during 1909 were $2,439,485, operating expenses and maintenance charges $846,626, net earnings $1,592,859, less taxes, &c., $71,986, bond interest $300,000 and dividends $973,866, surplus $242,005, provision for renewals $150,000, transferred to profit and loss account $92,005.

WOKING ELECTRIC SUPPLY CO. (LTD.)—At the meeting last week the chairman (Mr. John Ashby) said that the total revenue for the year (£13,837) was between £600 and £700 less than in 1908; but the expenditure was also nearly £300 less, owing largely to a reduction in cost of coal and to other economies effected. After meeting debenture interest and preference dividend, they were able to pay a dividend of 5 per cent. on the ordinary shares, to place £1,000 to reserve and to carry forward £617. 15s. 6d. Their customers were increasing at a greater ratio than at any time in the previous history of the company. On the whole the directors were satisfied with the report, and they considered the business of the company was in a healthy and satisfactory state. They were pushing their business in Chertsey and Addlestone, where they started doing work last year. At Chertsey they had opened a shop where the residents could obtain particulars as to cost of wiring, &c. They had been approached by towns where they had no powers to supply, and asked if they would supply current in bulk for distribution by the local authority or a local company. They were considering that proposal. They had put the matter into the hands of their co-director (Mr. Bowden). They had been asked to go to Cobham, but they should not incur further capital expenditure unless they could satisfy themselves that they would receive a fair and adequate return on it.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES.

DE LAVAL IGNITER CO. (LTD.) (109,408)—Reg. May 3, capital £1,500 in £1 shares, to carry on the business of manufacturers of and dealers in dynamos, electric motors, switchboards, resistances, general switchgear appliances, controllers, accumulators, &c., and to adopt an agreement with R. E. Bentley. Private company. R. E. Bentley is first director. Reg. office, 64A, Broad street, Birmingham.

HARPIN & CO. (LTD.) (109,290.)—Reg. April 20, capital £2,500 in £1 shares (1,500 6 per cent. cumulative preferred), to take over the business of electric lighting and power engineers carried on at Birmingham and Dudley as John H. Harpin & Co. Private company. First directors, F. C. N. Holloway, J. H. Harpin and P. T. Holloway. Reg. office, Bank Chambers, 47, Temple row, Birmingham.

NEW AFRICAN CONCESSIONS SYND. (LTD.) (109,342.)—Reg. April 29, capital £50,007 in £1 shares, to acquire the undertaking of the African Concessions Synd., to carry on the business of suppliers of electric light, heat and power, builders and constructors of public works, &c. First directors, W. A. Wills, Hon. R. J. Delays Tollemache, A. H. D. Cochrane, W. Praeger and P. S. Inskipp.

J. H. WALLACE & CO. (LTD.) (109,264.)—Reg. April 27, capital £5,000 in £1 shares, to carry on the business of hydraulic and general consulting engineers, electricians, manufacturers of and dealers in electrical and other machinery, &c. Private company. First directors, J. H. Wallace (chairman), J. F. Sickman, F. E. Greenwood, W. L. Bowker and J. Perry.

STATUTORY RETURNS.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—Return to Feb. 18 gives capital as £7,000,000 in £539,920 ordinary stock, £3,230,040 preferred ordinary stock and £3,230,040 deferred ordinary stock. All stock taken up. £7,000,000 paid. Mortgages and charges, nil.

HASTINGS & DISTRICT ELECTRIC TRAMWAYS CO. (LTD.)—Capital in return to March 29 is £500,000 in £5 shares (50,000 preferred). 40,000 preferred and 28,235 ordinary shares taken up. £5 per share called up on preferred. £200,000 paid. £141,175 considered as paid on the ordinary. Mortgages and charges, £250,000.

LEICESTERSHIRE & WARWICKSHIRE ELECTRIC POWER SYND. (LTD.) Return to Dec. 21 gives capital as £20,000 in £10 shares, 1,990 shares taken up. £10 per share called up on 1,470 and nil on 520. £17,740 paid (including payments in advance of calls). £40 remains in arrears. £20. 12s. 1d. paid on 10 shares forfeited. Mortgages and charges, £2,250.

LONDON ELECTRIC SUPPLY CORPN. (LTD.)—In return to March 11 capital is £1,050,000, in 200,000 ordinary shares of £3 each and 90,000 preferred shares of £5 each. 111,000 ordinary and 69,840 preferred shares taken up. £632,360 paid, including £160 on 160 shares forfeited. Mortgages and charges £387,355.

NEW ARC SYND. (LTD.)—According to return to Jan. 12 capital is £6,000 in £1 shares. 5,557 shares taken up. £1,557 paid. £4,000 considered as paid. Mortgages and charges, nil.

NORTHALLERTON ELECTRIC LIGHT & POWER CO. (LTD.)—In return to March 9 capital is £6,500 in 2,900 preference shares of £1 each and 12,000 ordinary shares of 6s. each, of which 1,151 preference and 4,561 ordinary shares have been taken up. £2,519. 6s. has been received. Mortgages and charges, £5,400.

RHYMNEY VALLEY & GENERAL ELECTRIC SUPPLY CO. (LTD.)—Return to Feb. 9 gives capital as £5,000 in £1 shares (2,500 preferred). 2,101 shares taken up. £1 per share called up on 930 ordinary and 2s. on 354 preferred. £955. 14s. paid, leaving £5. 6s. in arrears. £817 considered as paid on 817 shares. £4. 8s. paid on 80 forfeited preferred shares. Mortgages and charges, £900.

TURNERS & MANVILLE (LTD.)—Return to Feb. 22 gives capital as £50,000 in £1 shares. 20,012 shares taken up. £10,621 paid. £9,391 considered as paid. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

HINDHEAD & DISTRICT ELECTRIC LIGHT CO. (LTD.)—Issues from March 7 to April 9 of £950 debentures, part of a series of which particulars have already been filed.

PAIGNTON ELECTRIC LIGHT & POWER CO. (LTD.)—Issue on April 13 of £400 debentures, part of a series of which particulars have already been filed.

THOMAS L. SCOTT & CO. (LTD.) Particulars of £3,500 debentures, created Aug 20, 1909, have been filed, amount of present issue being £2,500. Property charged, company's undertaking and property, present and future, including uncalled capital. No trustees.

CITY NOTES.

MEMORANDA (May 18).—**Bank rate 4 per cent. (since March 17, 1910). Price of silver,** 24⅞d. per oz. **Consols** 81⅞—82 **for money; 81⅞—82⅛ for account. Consols Pay Day, June 1; Stock and Shares Continuation Days, May 25 and June 8; Ticket Days, May 26 and June 9; Pay Days, May 27 and June 10; Mining Shares Carry Over Day, May 24.**

PRICES OF METALS (London).—*Copper*, cash, 56⅛; three months, 56⅜. *Lead*, English, 12⅝—13¼; foreign, cash, 12⅝—12¾; three months, 12¾—12⅞. *Spelter*, 21⅝—22¼. *Tin*, English, 149—151; foreign cash, 150¼; three months, 151¼. *Iron*, Cleveland, cash, 49/7, and three months, 50/6.

BERGMANN ELEKTRICITATS-WERKE (A.G.) (BERLIN).—The turnover for the past year was 37,586,500 marks (£1,879,325), against 23,031,600 marks (£1,151,580) in 1908. An increase of capital (8,000,000 marks) has been decided on, bringing the capital to 29,000,000 marks.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the five weeks ended April 1 was 743,651 compared with 693,472.

CASTNER KELLNER ALKALI CO. (LTD.)—An interim dividend at the rate of 12½ per cent. is announced for the six months ended March 31.

COMPANIES STRUCK OFF THE REGISTER.—The following were struck off the Register of Joint Stock Companies on May 10:—

Electrical Bleaching Co., Electrical Regulating & Lighting Synd., Electrical Supplies, Rubber & Ebonite Co., Electric Lamp Regenerating Co., Electric Railways Co., Electro-Voelker Synd., Hillgrove & Armidale Electrical Corpn., McGuire Mfg. Co., Meyra Electric Co., Sulphides Reduction Co (New Process) (reg. March 27, 1902).

HOLSWORTHY GAS & ELECTRIC LIGHTING CO. (LTD.)—At the statutory meeting last week the chairman (Mr. W. T. Kivell) said that they hoped in a fortnight's time to be in a position to place the contract for the installation of electric light plant in Messrs. Christy & Co.'s hands.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAY (LTD.)—A dividend has been declared of 7s. per share, making 6 per cent. for the year (the same as for each of the last five years).

STOCK EXCHANGE NOTICE.—The Stock Exchange committee have ordered a further issue of $1,500,000 7 per cent. cumulative preference stock of the *Mexican Light & Power Co. (Ltd.)* to be quoted in the official list.

NOTES.

Temperature Coefficient of Copper.

IN our Correspondence columns during the last two or three weeks some reflections have been cast upon the temperature coefficient of copper adopted by the Engineering Standards Committee, and just as we were going to press last week we received a letter from Mr. F. J. O. HOWE, pointing out certain supposed anomalies. This letter appeared in our last issue, and in case it should be thought that the allegations are irrefutable, we think it well to make some further reference to it. Mr. HOWE, after starting with logarithms—which may very well be dismissed from the question as immaterial to the issue—remarks that no standard temperature is mentioned by the Engineering Standards Committee in their resolution adopting a coefficient of 0·00238 per degree F. He therefore adopts 60°F. as the standard temperature, and is surprised that he obtains some discordant results. Now, since Mr. HOWE is no amateur, we should have thought he would have known, in common with those engineers who are concerned with submarine cables, that the temperature implied by the Engineering Standards Committee is the one that is universally adopted as the starting point for temperature coefficients, namely, 32°F. The correct formula involves the square of the temperature; but for commercial purposes the Committee thought it sufficient to adopt 0·00238 as a mean value, and consequently a simple straight line law is the result. Thus the formula for the resistance R_t at temperature $t°$ in terms of the resistance at 32 F. is

$$R_t = R_{32}\{1 + 0{\cdot}00238(t-32)\}; \quad . \quad . \quad . \quad (I.)$$

or, if an observation at 60° F. is in question,

$$R_{60} = R_{32} \times 1{\cdot}00664. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (II.)$$

HAVING worked out a wrong result from the Engineering Standards Committee's coefficient through a wrong assumption, Mr. HOWE points out that it differs from what he understands to be Messrs. CLARK, FORDE and TAYLOR'S result, namely,

$$R_{32} = \frac{R_{60}}{1{\cdot}00665}.$$

This is practically identical with the result (II.) given above; and, indeed, it would be curious if it were not; for surely it is common knowledge that the temperature coefficient obtained by Messrs. CLARK, FORDE and TAYLOR was adopted by the Engineering Standards Committee, and we believe we are right in saying that the figure has been verified by any number of independent measurements. We think our readers will agree that Mr. HOWE'S statements are rash in the extreme, and if the contents of the book recently reviewed in our columns are of the same character, we can only say that the letter in question gives very good support to the review so adversely criticised by "A Lover of Fair Play," whose criticisms would have been better left unwritten.

Free Trade *versus* Protection.

AT the meeting last Monday, organised by the National Electrical Manufacturers' Association to discuss the comparative effects of Free Trade and Protection upon the electrical industry, the audience was not quite so large as might have been expected, but there is no question that all were keenly interested. Although the sympathy of the meeting seemed to lean toward Protection, a good deal of support was given to Free Trade. Mr. J. E. KINGSBURY, in opening the discussion, as will be seen in another column, laid stress upon the advantages of keen competition, which necessarily resulted in the highest possible efficiency. He remarked that the extent of the imports that we desired to exclude amounted to only about 10 per cent. of the home consumption, and although we might

Digitized by Google

exclude this proportion, and might have our home market more to ourselves, there was a possibility that our foreign market would become less and our output as a whole diminished. To a large extent the argument was one of the general good against that of a section of the community. Mr. HUGO HIRST, on the other hand, spoke as one who had suffered from the present state of things. He laid stress upon the desirability of the country being more of a producer and less of a consumer. Under proper conditions there was no reason why the great bulk of the population should not be producers, with great advantage to the country as a whole. Also, Protection would mean a larger output and thus diminished costs.

WE think that the impression left on the minds of many of the audience was that much of the argument of both sides consisted simply of expressions of opinion, whereas it would be very desirable, if possible, to produce facts. Perhaps at the adjourned meeting we may be told how much of the present position is really due to competition at home and how much to competition from abroad. Also, it would seem, if Mr. KINGSBURY is right in his 10 per cent., that the maximum increase in output under Protection would be about 10 per cent., which is not very much, and this is on the assumption that our exports are not reduced by retaliation. There is not much doubt that in past days, when other countries were not producers, we had nothing to lose by Free Trade. The position at present is by no means so clear. Unfortunately, the subject is exceedingly complex, and we doubt whether more than a small proportion of those who have the subject at heart have sufficient knowledge of political economy to enable them to arrive at any clear judgment. It is also, perhaps, a little doubtful whether any discussion will change many minds. Nevertheless, we welcome the step taken by the National Electrical Manufacturers' Association, and we hope it will result in a clearer understanding of the case.

Dolter Surface Contact System.

OF all the troubles from which surface contact systems have suffered, that of live studs has been the most persistent. A system may work perfectly in theory, and it may appear that such a thing as a live stud is almost an impossibility, and yet in practice this trouble is very liable to occur. This is, doubtless, the reason why so many systems have failed. The latest to suffer in this direction is the Dolter. It appears that live studs have been noticeable at Torquay to a larger extent than the Board of Trade think desirable. Certificates have been issued from time to time permitting the system to continue in use, but with the intimation that the conditions must improve. Some little time ago a certificate was issued by the Board of Trade for one year, with the proviso that if matters did not improve within the first six months of that time no further certificate would be granted. This period has now expired, but, unfortunately, there has not been the desired improvement, and consequently the Town Council are considering what are the best steps to be taken. It is to be regretted that this result should have ensued, as in certain towns a surface contact system offers very marked advantages from the æsthetic point of view.

Electric Traction in the Hoosac Tunnel.—The "Electrical Review and Western Electrician" states that plans are under consideration by the Boston & Maine Railway for the elimination of coal and oil burning locomotives in the Hoosac Tunnel in Massachusetts. Should the change be made, a power plant will be established near South Adams, the tunnel will be lighted and ventilated by means of electricity, and only electrical engines will be used to draw the trains through the tunnel.

Electricity Meter Approved by the Board of Trade.—On May 21st the Board of Trade approved meter No. 307,722, deposited at the Board of Trade on Nov. 14, 1908, by Messrs. Siemens Bros. Dynamo Works (Ltd.) and known as the Siemens-Schuckert Alternating Current Meter, Type W10, and the means provided for fixing and connecting such meter, described in the specification and instructions deposited with the Board of Trade and dated and numbered May 7, 1910, and H. 6,284.

Automatic Telephony in Chicago.—According to the "Electrical Review and Western Electrician," the Subway Telephone Construction Co., which recently obtained the telephone franchise of the Illinois Tunnel Co., propose to instal a complete automatic telephone system in Chicago, the system to be in operation by June, 1911. With regard to the charges, the Company state that after 10,000 telephones have been installed, the prices for unlimited service in the business districts will be :—10,000 to 15,000 telephones, 7s. per month ; 15,000 to 17,500 telephones, 14s. per month ; 17,500 to 20,000 telephones, 21s. per month ; and 20,000 telephones and over, 28s. per month. It is stated that the charges will not at any time exceed 16 guineas annually for telephones in business establishments and £10 annually for instruments in private residences.

Magnetisation Curves for Small Iron Wires.—In a recent issue of the "Physical Review" Mr. J. A. Veazey describes an investigation of the magnetisation curves for a sample of iron wire one mil in diameter, the experiments being made with the object of obtaining an idea of the relative magnitude of the molecules, or groups of molecules, constituting the elementary magnets of which a large magnet is thought to consist. If the magnetisation curves showed changes indicative of sudden alteration of magnetic flux in the wire the inference would be that the groups were of the order of one mil in magnitude. The apparatus used was a modification of that employed by Ewing. The curves obtained were perfectly smooth, and the conclusion reached is that the elementary magnets, of whatever kind they may be, are less than one mil in order of magnitude.

Long Lived Tungsten Lamp.—According to the "Electrical World" a 250 watt tungsten lamp in the bakery of the Arlington Hotel, Hot Springs, on April 11th closed its unusual career after having burned continuously for 24 hours a day since October 7, 1908, thus accomplishing the extraordinary life of over 13,000 hours. On one of the three known occasions when the lamp was extinguished it was turned out for the inspection of the members of the Arkansas Public Utility Operators' convention in session at the hotel, and although its long life at that time occasioned much interest, it continued burning 11½ months more, finally having its filament separated by an accident to the 8 H.P. steam engine driving a dish-washing machine near by. This engine was mounted but 6 ft. away from the lamp, and was operated a number of hours each day during the life of the lamp. On the date mentioned the belt came off the engine and the latter ran away. When the excitement had subsided the lamp was found to be extinguished.

Royal Commission on Mines.—The King, on the recommendation of the Home Secretary, has approved of the reconstitution of the Royal Commission on Mines for the purpose of an inquiry into the health and safety of persons employed in metalliferous mines and quarries. The new commission will consist of Sir Henry Cunynghame, K.C.B. (chairman), Mr. R. A. S. Redmayne (Chief Inspector of Mines), Dr. J. S. Haldane, M.D., F.R.S., Mr. J. S. Ainsworth, M.P., Mr. R. M. Greaves, Mr. R. A. Thomas (General Manager of the Dolcoath Mine, Cornwall), Mr. R T. Jones (Secretary of the North Wales Quarrymen's Union), Mr. W. Lewney (Secretary of the Furness Iron Ore Miners' and Quarrymen's Union), and Mr. U. Lovett (Secretary of the National Union of Quarrymen). Mr. T. E. Bettany and Mr. G. W. Chrystal, of the Home Office, will act as joint secretaries of the Commission.

Statistics of Cable Breakdowns.—In a recent issue of the "Electric Railway Journal," Mr. H. C. Stott, of the Interborough Transit Co., gives the following record of high-tension cable breakdowns on the 11,000-volt distribution system of that Company from January, 1904, to January, 1910.

Year.	Miles of cable.	In joint.	In bend.	In cable.	External causes.	Total.
1904	330	1	0	1	1	3
1905	351	0	0	1	0	1
After Earthing the Neutral.						
1905	351	0	1	1	0	2
1906	353	3	0	3	5	11
1907	353	1	0	0	5	6
1908	368	1	0	0	4	5
1909	371	3	0	1	5	9
Total		9	1	7	20	37

NOTE.—External causes include mechanical injury, steam leaks and burning of the armouring by other cables.

"The Central."—The current issue of this journal is a "memorial number" devoted to the life and work of Prof. W. E. Ayrton, who died on November 8, 1908. The issue is divided into parts, the first, describing Prof. Ayrton's life, being written by Mr. Maurice Solomon. The second on "Prof. Ayrton and His Work," is written by Prof. T. Mather, F.R.S., who is certainly qualified on all counts to undertake such a task. The third is not the least useful, for it consists of a full list of Prof. Ayrton's publications between 1870 and 1907. The number is illustrated by photographs of the subject of the issue at various times of his life. No electrical engineer will deny the great influence which Prof. Ayrton had on the progress of the profession, and thus to have in a compact form a record of his achievements is an advantage which cannot be over estimated. We congratulate the compilers on the work they have done. Although this issue is complete in itself we gather that there is more to follow.

Obituary.—JOHN OLDHAM.—Sad and unexpected news comes from the River Plate. We have been so accustomed to regard Mr. John Oldham (Manager of the River Plate Telegraph Co., and since 1874 representing the Western Telegraph Company's interests in Argentina and the Plate) as a permanent institution that the news of his sudden death on April 18th comes as a shock. He first left England for the Plate in 1865, and resided in Uruguay and Argentina up to the day of his death, with infrequent journeys home. He was always an acceptable negotiator with the Governments on his Companies' behalf, and quite recently he had almost seen the completion of the negotiations of the direct cable between Europe and Argentina. Mr. Oldham was greatly respected and possessed many friends, with whom we join in tendering our sincere condolences to his family.

Mr. Oldham was born near Manchester in 1836. He was associated with the earlier days of telegraphy, having served the old United Kingdom and the British and Irish Magnetic Telegraph Companies. He subsequently had some experience at Henley's factory at Woolwich, and ultimately was selected by Mr. Matthew Gray to undertake the establishment of the Monte Video-Buenos Ayres communication, partly by cable and partly by a hundred miles or so of land lines over a country not the most convenient for transit, nor then by any means safe, owing to the frequent troubles and recurring revolutions amongst the neighbouring Republics. Mr. Oldham personally superintended the whole of this difficult and dangerous work from the first. He was a Chevalier of the Order of the Rose.

ALFRED NUTT.—It is with great regret we record the death of Mr. Alfred Nutt, head of the well-known firm of London publishers, which sad event occurred under distressing circumstances on Monday. Mr. Nutt was with his son in Paris taking a stroll on the banks of the Seine, when his son, who was in a light vehicle, was accidentally precipitated into the river. Mr. Nutt, a powerful swimmer, went to the rescue, but was caught by the current and drowned. His son was saved. Mr. Nutt had a remarkable grasp of all matters relating to technical literature, and was the sheet anchor of booksellers and book readers in search of works of a technical and special character in all languages.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

As already announced in these columns, the 15th Annual Convention of this Association will take place at Glasgow from June 14th to 17th inclusive. The meetings in Glasgow will be held at the Institution of Engineers and Shipbuilders in Scotland, Elmbank-crescent, where there will be a reception room for transacting the business of the convention. It is requested by the Council that members, delegates and visitors (including ladies) will register their names on arrival. They will then be handed distinctive badges, and can obtain any papers to which they may be entitled. These badges will only be obtainable after registering, and are supplied free of charge. They should be worn throughout the convention.

The convention proper will open at 10 a.m. on Tuesday, June 14th, when the Lord Provost of Glasgow (The Hon. A. McInnes Shaw) will welcome the members of the Association. Mr. W. W. Lackie, chief electrical engineer of the Glasgow electricity department, will then deliver his presidential address. A Paper on "Commercial Progress," by Mr. A. C. Cramb, chief electrical engineer of Croydon, and Mr. H. Collings Bishop, chief electrical engineer of Newport (Mon.), will be read and discussed. At 1:15 p.m. the Tramways and Electricity Committee of the Glasgow Corporation will entertain the members and delegates (including ladies) to luncheon at the City Chambers. After lunch, brakes will leave the City Chambers to visit the Springburn sub-station of the electricity department, the Pinkston power house of the tramways department and the Port Dundas electricity works of the electricity department. In the evening a reception and conversazione will be held at the City Chambers by the Lord Provost, Magistrates and Town Council of the City of Glasgow. On Wednesday, June 15th, the members present at the meeting will leave Glasgow at 8:25 a.m. by special train for Edinburgh. A meeting will be held at 10 a.m. in the Free Gardner's Hall, Picardy-place, Edinburgh, when the Right Hon. the Lord Provost of Edinburgh will welcome the convention to that city. A Paper on "Steam Turbines and Condensing Plant," by Mr. F. A. Newington, chief electrical engineer of Edinburgh, will be read and discussed, as will also one on "Mixed Pressure Turbines," by Mr. Ashton Bremner, chief electrical engineer of Burslem. At 1:15 p.m. members and delegates (including ladies) will be entertained to luncheon by the Corporation of Edinburgh at the Music Hall, George-street. In the afternoon a visit will be paid to the works of the electricity department in Macdonald-road. On the Thursday, meetings will be held in the Rankine Hall of the Institute of Engineers and Shipbuilders, Glasgow. A discussion will first take place on the "Advantages of Continuous Records of Costs and Steam Consumption." This will be opened by Mr. Geo. Wilkinson, chief electrical engineer of Harrogate, and Mr. C. E. C. Shawfield, chief electrical engineer of Wolverhampton. There will also be a discussion on the "Cheapening of the Cost of Mains and Services," which will be opened by Mr. S. E. Fedden, chief electrical engineer of Sheffield, and Mr. S. J. Watson, chief electrical engineer of Bury. In the afternoon the St. Andrew's Cross power station of the electricity department, the Coplawhill works of the tramways department, and the generating station of the Govan electricity department will be visited, or alternative visits may be paid to the electricity works at Partick, the power station of the Clyde Valley Electric

Digitized by Google

Power Co., at Yoker, and the shipbuilding works of Messrs. Beardmore (Ltd.) at Dalmuir. A special visit will be arranged for the ladies of the party to Rouken Glen. In the evening the annual dinner of the Association will take place at the Windsor Hotel, Glasgow. On Friday the annual general meeting of the Association will be held in the Rankine Hall of the Institute of Engineers and Shipbuilders.

Special arrangements are being made for the ladies accompanying members to visit places of interest in both Glasgow and Edinburgh, while the following works will be opened for the inspection of members during the time of the convention: Messrs. Mavor & Coulson, Babcock & Wilcox, Craigpark Electric Cable Co., Bruce Peebles & Co., and the electricity works of the Greenock and Paisley Corporations.

We are, as usual, making special arrangements for giving full reports both of the Papers and discussions at this convention, and our issue of June 17th will contain an account of the proceedings up to the close of the meeting on Thursday, June 16th.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. A. Fraenckel and Mr. B. J. M. Lane conclude their article on "Short-circuit Losses in Alternating-current Commutator Motors."

Mr. F. Fernie contributes an article on "Electrolysis of Underground Mains."

The National Electrical Manufacturers' Association held a meeting on Monday last, when the comparative effects of Free Trade and Protection upon the electrical industry were discussed.

The programme for the Convention of the Incorporated Municipal Electrical Association at Glasgow has been issued.

We conclude our account of the new generating station of the Westminster Electric Supply Corpn.

The report of the proceedings of the Board of Trade and of the Light Railway Commissioners for the year 1909 is abstracted in another column.

The Board of Trade have refused to grant further certificates for the use of the Dolter system at Torquay.

Legal.—The Court of Appeal yesterday (Thursday) allowed the appeal of Eccles Corporation against the judgment of Mr. Justice Eve dismissing their action for an injunction to restrain Salford Corporation from authorising the South Lancashire Tramways Co. to run over a portion of tramway track in Eccles.

Mr. Justice Grantham and a special jury yesterday (Thursday) commenced the hearing of an action brought by a builder against Marylebone (London) Borough Council for damages for injuries by electric shock alleged to have been received in consequence of the negligence of the Council's servants in not cutting off electric current from a cable laid through a house which was being rebuilt by plaintiff.

INSTITUTIONS AND SOCIETIES.

Royal Society of Arts.—The Council of this society have elected the Hon. Theodore Roosevelt a life member under the terms of the by-law which empowers them to elect annually not more than five persons who have distinguished themselves by the promotion of the society's objects. The first American member of the society was Benjamin Franklin, who was elected in 1755.

National Electrical Manufacturers' Association.—A meeting of this Association will be held at Caxton Hall on Monday, June 6th, at 8 p.m., when the discussion on "The Effect of Free Trade or Protection on the Electrical Industry" will be resumed. Mr. E. Garcke will open the discussion. Admission will be by visiting card.

The Institution of Civil Engineers.—In consequence of the death of His Majesty King Edward VII., the council have decided that the conversazione shall not be held this year. The eighteenth "James Forrest" lecture will be delivered at the Institution on June 22nd, at 8 p.m., as already announced.

Illuminating Engineering Society.—At the meeting on Monday last the report of the council for the session 1909-10 was presented. In this it is mentioned that the membership of the society now exceeds 220, and the results of the first session are considered satisfactory. Prof. S. P. Thompson, F.R.S., remains as president, and the council has been increased by the addition of Dr. W. Eccles, Mr. A. H. Stokes and Mr. A. H. Seabrook.

New Building of the Institution of Civil Engineers.—We have received from the secretary a copy of a pamphlet giving details of the new Institution building which is to be erected at the corner of Great George-street and Princes-street. The premises will occupy an area of some 21,000 sq. ft. On the ground floor will be situated the council and committee rooms, the reading rooms and general offices. The first floor will be occupied chiefly by the lecture theatre, the great hall and the main library, the apartments being arranged and connected together in a convenient manner for the reception of large numbers of people. Further library accommodation will be afforded on the second floor, where also will be a writing and smoking room for the members. Provision for the general service of the premises, including the heating and ventilating apparatus, extra cloak rooms, &c., and for storage, will be made in the basement and on the third floor. It is confidently anticipated that the new premises will lend themselves satisfactorily to the purposes of the society and the needs of its members; and an interesting feature in the construction of the building will be the introduction of the timbers and certain other products of various parts of the British Empire, which may serve to symbolise in some degree the close relationship of those who constitute the Institution of Civil Engineers in all parts of the world.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, May 27th (to-day).

Physical Society of London.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: (1) "On an Oscillation Detector actuated solely by Temperature Variation of Resistance," by Dr. W. H. Eccles. (2) "Exhibition of a Resonance Transformer," by Mr. A. Eagle. (3) "The Limitations of the Weston Cell as a Standard of Electromotive Force," by Dr. S. W. J. Smith.

MONDAY, May 30th.

Railway Signal and Telegraph Engineering Institute.

7:30 p.m. Meeting at St. Marylebone Church Institute, Central Hall, 59 and 60, Paddington-street, W. Paper on "Automatic Switches, Relays and Signals," by Mr. F. W. R. May.

TUESDAY, May 31st.

The Faraday Society.

8 p.m. Meeting in the Rooms of the Chemical Society, Burlington House, Piccadilly, W. Papers on (1) "Some Practical Experiments of the Sheradising Process," by Mr. J. W. Hinchley. (2) "Note on the Composition of Eutectic Mixtures," by Mr. C. H. Desch. (3) "Relations between Critical Temperature, Boiling Point, and Expansion Coefficient of Phosphorus Pentachloride," by Mr. E. B. R. Prideaux. (4) "Thermic Reactions in Vacuo." Parts I., II., and III. by Messrs. F. E. Weston and H. R. Ellis. Demonstration of (1) "Apparatus for Rapid Determination of the Resistance of Liquids." (2) "Apparatus for the Determination of Specific Resistance of Oil," by Messrs. C. V. Biggs and W. P. Digby.

WEDNESDAY, June 1st.

Royal Institution.

3 p.m. Meeting at Albemarle-street, Piccadilly, W. Lecture on "The Constitution and Internal Structure of Alloys," by Mr. W. Rosenhain (Lecture II.).

THURSDAY, June 2nd.

Röntgen Society.

8:15 p.m. Meeting at 20, Hanover-square, W. Papers on "Practical Observations on Everyday X-Ray and Electrical Work, Filtration of Rays, Measurement of Rays, Rapid Stereoscopic Method, &c.," by Dr. H. Pirie and on "Recent Improvements in Radiographic Technique," by Dr. R. Knox. A new Form of Apparatus for Producing Rythmical Variations in the Strength of Electrical Currents will be shown by Dr. Hampson.

SATURDAY, June 4th.

Royal Institution.

3 p.m. Lecture on "Electric Heating and Pyrometry," by Prof. J. A. Fleming, F.R.S. (The Tyndall Lectures.) (Lecture I.)

The Corps of Electrical Engineers (London Division).

Commanding Officer, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, May 30th, "A" Company.—Recruits' infantry drill, 6 to 6:45 p.m. Company drill, 7 to 9:30 p.m.

Tuesday, May 31st, "B" Company.—Company Drill, 7 to 9:30 p.m.

Wednesday, June 1st.—Gymnasium, 8 to 9:30 p.m.

STANDARDISATION OF FUSES.*

BY H. W. KEFFORD.

Summary.—After pointing out the desirability of standardisation, the author gives particulars of tests on a number of representative types of fuses up to a capacity of 50 amperes, and discusses the ratio between the rated current and the normal fusing current. He then considers the general regulations for the construction and operation of standard fuses and describes a non-interchangeable fuse system. He refers to the testing of fuses, and finally puts forward some suggestions as the basis of a specification for standard fuses.

The standardisation of electric fuses and the enforcement of more stringent regulations with regard to their design and use would contribute greatly to the increased safety of electrical installations and would put the manufacture of this class of apparatus on a more uniform and scientific basis. The difficulties to be overcome before a standard system of fuses can be brought into general use are certainly numerous, but delay renders the problem more and more complex. If we would foster the popularity of electrical applications and the prosperity of the industry we must create and maintain confidence in the safety, reliability and convenience of electrical power by every possible means. In addition to contributing largely to the attainment of this end, the standardisation of fuse design would undoubtedly conduce to economy in manufacture and result finally in a reduction of cost. Up to a certain point it is a very simple matter to determine the behaviour of a fuse when blown under working conditions, and this fact renders still more inexplicable the retention of many types which are wholly inadequate and of others which are needlessly elaborate. In the present Paper the subject is dealt with from a practical rather than academic point of view, the object being, if possible, to suggest a few lines along which certain essential questions may be tackled. Up to the present time the tests referred to have been confined to low-tension fuses up to a normal carrying capacity of about 60 amperes, but it is hoped to continue the experiments on fuses of much larger capacity.

The complete specification of a line of fuses will embrace (*a*) a definition of the "marked" or "rated" current in terms of the "limiting" current (also called the "normal fusing" current); (*b*) a standard range of rated-current values and voltages; (*c*) a definition of one or more points on the "time-overload" curve of each fuse; (*d*) regulations as to non-interchangeability, temperature rise, freedom from deterioration and perfect operation under all conditions; (*e*) specifications for the standard method of carrying out short-circuit, temperature rise and overload tests.

Rated Current.—As is well known, the chief characteristic of a fuse for quantitative purposes is its "time-overload" curve and the asymptotic current value of this curve to which the name "normal fusing current" has been given, but which will be referred to in this Paper as the "limiting current." The strict definition of this is the minimum steady current which will produce fusion after an infinite time interval, but for practical purposes we might substitute with advantage a definite time interval—say four hours. The limiting current or limiting overload is the one fundamental quantity to which any definition of rated current should refer. An appropriate way of defining the rated or marked current of the fuse is as follows: A fuse which is rated at R amperes must fuse within four hours when carrying a times its rated current, but must be capable of carrying $a-\alpha$ times its rated current for at least four hours without fusing. If L amperes is the limiting current, the rated current R amperes must lie between L/a and $L/(a-\alpha)$.

The values chosen for a and $a-\alpha$ depend on a large number of practical considerations, and should also be selected with a view to facilitating the application of the above definition in factory and test house. Thus the difference α between the two values may be looked upon as a measure of the accuracy with which the specified conditions can be attained in manufacture. The latter point recalls the fact that the Wiring Rules of this Institution require that no fuse shall carry more than 200 per cent. overload without fusing (*i.e.*, $a=3{\cdot}0$), whereas the rules of another recognised authority in this country restrict the permissible overload to 50 per cent. ($a=1{\cdot}5$). The writer has recently heard of suggested modifications to the overload regulation from two independent sources, one of which was a proposal to permit an overload of 300 per cent. ($a=4$), while the second authority was of the opinion that the permissible overload should be even less than 50 per cent. if manufacturers could work to a narrower limit. If, as may be assumed, the smaller overload is the one dictated by considerations of safety, irrespective of manufacturing limitations, whereas the higher figure is based on a compromise between what is desirable and what is present practice, these figures furnish one of the most striking arguments for the need of a system of non-interchangeability for fuses of small capacity. This point will be dealt with more fully later in the Paper. The regulations for enclosed fuses by the Underwriters' Association in the United States, which have been framed with the co-operation of manufacturers, fix the values of a and $a-\alpha$ at 1·25 and 1·10 respectively, but these figures were only decided upon after manufacturers had endeavoured to work to a smaller value of α than 0·15, as specified above. These close limits are in marked contrast with the figures quoted above.

The results of an experimental investigation of the properties of current commercial types of fuses should give a reliable and useful indication of the possible values of a and $a-\alpha$, the limits between which the ratio (limiting current)/(rated current) must lie, and it becomes a relatively simple matter to determine whether this ratio should have the order 4 or 1·5. In drawing inferences from such tests due weight must be given to the many other properties which are closely connected with the ratio a, and observations must be made of running temperature, voltage drop, behaviour when blowing on overload and short-circuit and general reliability and safety.

A table in the Paper summarises some tests carried out on a representative variety of fuses in common use; a few of the fuses tested are illustrated in Fig. 1. A distinctive letter has been given to all fuses supplied by one firm and the various sizes and types are

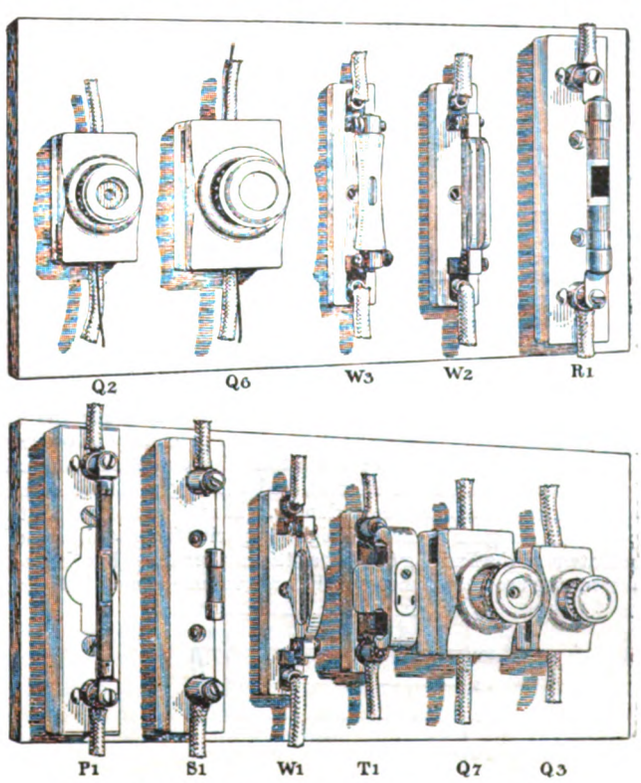

FIG. 1.—SOME REPRESENTATIVE TYPES OF FUSES TESTED.

denoted by a number which follows this letter. A few particulars of the tests on the fuses illustrated are given in the table herewith. Fig. 2 illustrates typical curves of voltage drop, while Fig. 3 shows the watts losses corresponding to the voltage drops plotted in Fig. 2.

Before proceeding to make any deductions from these results, the

author considers one or two points which may serve for general guidance. Taking first the case of a bare fuse wire stretched between two terminals, let us assume that a line of fuses, all of equal length, is to be designed. It will be found that the voltage drop is proportional inversely to about the square root of the limiting current. Owing to the desirability of preventing the pressure drop across the fuse becoming excessive, the same value of a is not advisable for large and small fuses; it may be desirable to increase the value of a as the normal working current diminishes. In the case of fuses of the totally enclosed type, we have also to consider the effects of the increased cooling facilities and capacity for heat of the fuse enclosure. Owing to the large radiating surface, the size of wire for a given limiting current is reduced, and the drop of volts may therefore become large if the length of the fuse is not reduced or a metal

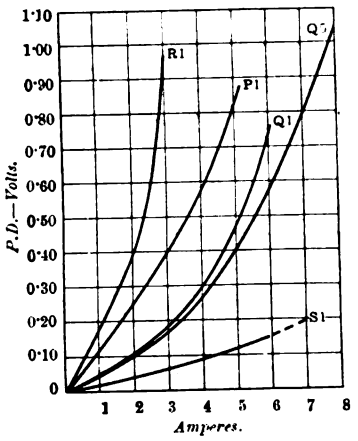

Fig. 2.—Pressure Drop across Fuses, rated at 4 amperes.

adopted which has a low melting point. If the fuse is very short, on the other hand, conduction and dissipation of heat from the terminals will play an important part and exercise a similar influence in increasing the voltage drop and power loss. In order to reduce these two quantities to economical and safe limits, it becomes necessary to rate the smaller fuses at a lower percentage of the limiting current. Since well-designed fuses of the enclosed type may be made very much shorter than a corresponding open-type fuse for the same voltage, advantage should be taken of this possibility in order still further to reduce the losses; the alternative course of using a low melting-point metal is far inferior, and the larger volume of metal required may prove a source of danger. It may be noticed that it is open to the designer to rate the higher capacity fuses at the same low percentage of the limiting current as the smaller sizes; but this, again, involves the use of an unnecessarily large volume of metal, a proceed-

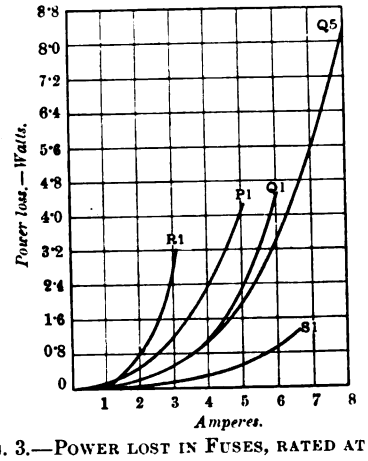

Fig. 3.—Power lost in Fuses, rated at 4 amperes.

ing to be avoided as much as possible, particularly for fuses carrying heavy currents and liable to severe short-circuits. From a purely utilitarian standpoint it is probably correct that small fuses should carry higher overloads than fuses of large capacity, and all that might be said from this point of view may be best summed up by considering a 5-ampere fuse capable of carrying 10 amperes, and a 100-ampere fuse permitting a continuous load of 200 amperes.

The most important factor in determining a standard value or values for the ratio a=(limiting current)/(rated current) is the maximum safe overload to which an electric circuit may, on the average, be subjected; the results arrived at from this consideration can, if necessary, be modified to meet the limitations of manufacture. The possibility of more economical utilisation of the apparatus protected is a natural consequence of adopting fuses which restrict within narrow limits the overload which may be imposed on a circuit. For fuses up to 50 amperes a maximum permissible continuous over load of 25 per cent.—as in the United States—is not wholly desirable, since most circuits and apparatus should be designed to withstand this amount of overload without injury, and, further, even the best system of non-interchangeability would fail and the circuits be overfused if users and wiremen found that they could not overload circuits to more than 25 per cent. even for short periods. Fuses run normally at only 20 per cent. under the limiting current must of necessity have fusible metal of low melting point if the running temperature is not to be unduly high; for reasons of equal importance, the use of such metals is bad.

Nearly all the metals used for fuses suffer oxidation if run at temperatures much above that corresponding to 50 per cent. of their limiting current, although if silver be employed the rated current may certainly be as much as 65 to 70 per cent. of the limiting current without the occurrence of any deterioration. The permissible overloads corresponding to a rating 50 and 70 per cent. of the limiting current are 100 and 43 per cent. respectively, and the large difference in these overload capacities is of interest as showing the superiority of a non-oxidising metal like silver if it is desired to reduce to a minimum the possible overload. Assuming, as will be afterwards shown, that copper and silver are the only metals suitable for standardised fuses, we can take as a rational basis

Copper.—Minimum value of $a=2{\cdot}00$.
Silver.—Minimum value of $a=1{\cdot}43$.

Attention may be drawn to Fig. 4, which shows the approximate variation of temperature of a bare copper fuse wire with increasing currents up to the melting point and limiting current. The dotted curve is for silver fuse wire. The rapid rate at which the temperature rises after about 50 per cent. of the limiting current has been passed is noteworthy, and has an immediate bearing on the subject of rating.

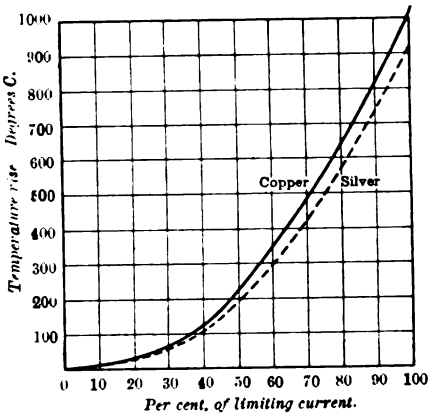

Fig. 4.—Approximate Temperature Rise of Copper and Silver Fuses in relation to the Percentage of the Limiting Current

Standard Rated Current Values and Voltages.—An excellent plan seems to be the adoption of a standard voltage of 500 for all sizes, and the addition of a range of small capacity fuses for 250 volts for use on lighting circuits where small size and cheapness are important and very severe short-circuit conditions do not often occur. In proposing a standard range of rated currents the important point is to reduce the number of sizes to a minimum while providing for all current values with a reasonable margin of overload capacity. A convenient subdivision is with steps differing by multiples of 5 amperes, giving, say, 5, 10, 15, 20, 30, 40 and 50-ampere sizes. At least one smaller capacity than 5 amperes is required, and since 4 and 6 amperes are standard values with a large number of manufacturers, a satisfactory completion of the range will be to adopt multiples of 2 amperes up to a value of 6 amperes, the complete standard line becoming 2, 4, 6, 10, 15, 20, 30, 40, 50 amperes.

Definition of Points on "Time-current" Curve.—The main object in defining further points on the "time-current" curve, in addition to the limiting current, is to ensure that the fuse will give adequate protection against very heavy overloads or short-circuits, and to restrict within limits its sluggishness of action or "time element." From a practical point of view a regulation of this kind is useful, because compliance with it can be readily checked, and it may be so framed as to eliminate the use of too large a mass of fusible metal and other faults of design. In order to be of real value such a regulation should require that a fuse shall melt within a fixed time—say, 1 minute—when loaded with a certain multiple of its limiting current—say, double that value.

(To be concluded.)

SHORT-CIRCUIT LOSSES IN ALTERNATING-CURRENT COMMUTATOR MOTORS.

BY A. FRAENCKEL, DR.ING., AND B. J. M. LANE, B.SC.

(*Concluded from page* 233.)

Summary.—Results of experimental researches on the losses due to the short-circuit currents in alternating-current commutator motors are given. These show a rapid decrease of the loss with increasing speed, other conditions being equal. An explanation of this phenomenon is given, and oscillograms are shown from which the decrease of the short-circuit current with increasing speed, and for a given short-circuit E.M.F., is deduced. The influence of the short-circuit currents on the line pressure and current is illustrated.

Experimental Results.

In order to verify this theory experiments were carried out showing how the losses depend on the speed, and how the brush contact resistance is influenced by the current-density and

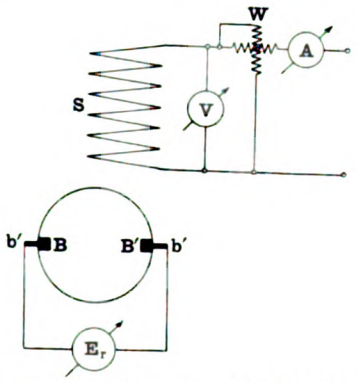

Fig. 7.—Bi-polar Scheme of Experimental Machine.

speed. Oscillograms were taken showing instantaneous values of short-circuit currents and corresponding induced E.M.F.s The experimental determination of the short-circuit losses was carried out by measuring the power supplied to the exciting coil, firstly when no brush was on the commutator, and secondly when the brushes were on and placed in the neutral zone, the main flux being the same in both cases.

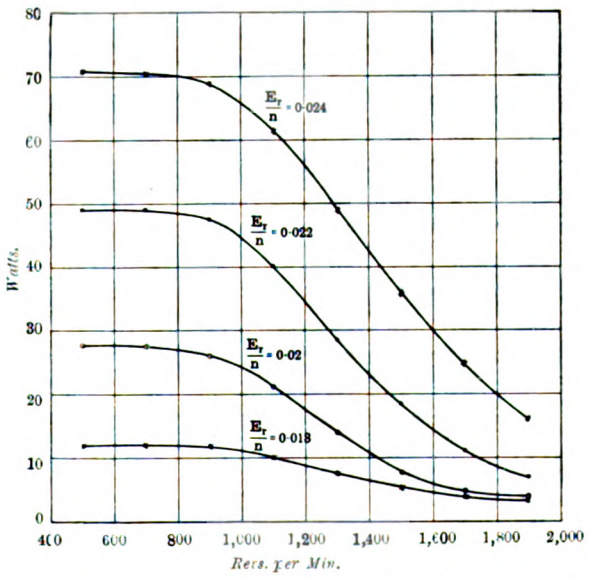

Fig. 8.—Curves of Short-Circuit Losses for two "Z" Carbon Brushes on Commutator and in the Neutral Zone.
Dimensions of each brush surface = 10 × 26 mm.

There are two ways of measuring the flux. Consider the armature of an excited two-pole machine as being driven by means of an auxiliary motor. There is a resultant E.M.F. between two brushes placed in the axis of the exciting winding, and this E.M.F. is proportional to the main flux and to the frequency of its pulsations. Another resultant E.M.F. may be obtained between two brushes placed in the neutral zone, this E.M.F. being proportional to the flux and the speed. The former may be expressed as follows

$$Ep = \frac{\pi}{2\sqrt{2}} \cdot \frac{N}{a} \cdot c \cdot f \cdot \phi_{max.} 10^{-8} \text{ volt},$$

while the latter is

$$E_r = \frac{1}{\sqrt{2}} \cdot \frac{p \cdot n}{60} \cdot \frac{N}{a} \cdot \phi_{max.} 10^{-8} \text{ volt},$$

where N = total number of armature conductors,
$2a$ = number of parallel circuits of the armature,
c = frequency of the exciting current,
p = number of pairs of poles,
$\phi_{max.}$ = maximum value of the flux pro pole,
n = revolutions per minute.

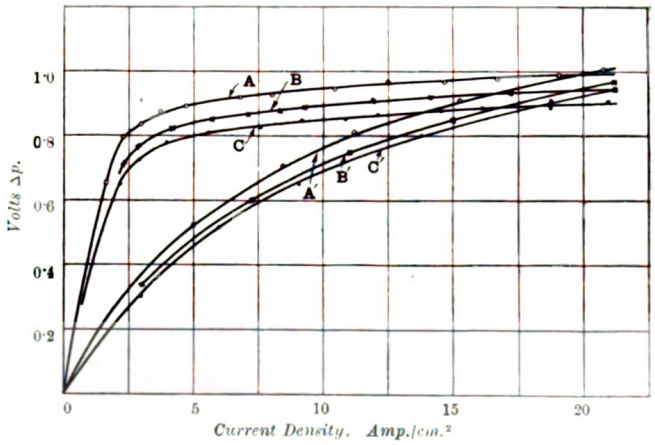

Fig. 9.—Curves showing Voltage Drop over Brush Contact Resistance.

It is seen from the above that Ep is dependent upon the factor f. This factor is dependent upon the field distribution and upon the form of the windings. For a sinusoidal distribution of the flux and a distributed armature winding f is equal to $2/\pi$. However, it is quite evident that the short-circuit currents will have an effect upon the field form, and consequently f will change in value. The short-circuited windings are concentrated and superimpose a field differing in form from that produced by the distributed exciting winding. Thus the relation between flux and voltage will not be constant. On the other hand, E_r is quite independent of the field distribution, and depends only upon the total value of the flux ϕ. Thus in the following we shall deal with E_r. This method cannot be used at standstill because E_r is zero, but this disadvantage does not come into consideration, since at standstill the losses

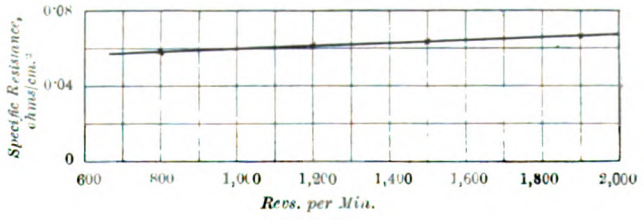

Fig. 10.

vary greatly with the position of the brush relative to the segments, and strong heating of commutator and brush occurs so that no exact measurements can be made.

The experimental machine consisted of a four-pole 5 H.P. repulsion motor having 99 commutator segments. The width of each segment = 4·5 mm., and the mica width = 0·5 mm. The armature was provided with a wave winding, so that two armature turns were lying between neighbouring segments. The stator winding was distributed in 24 slots, there being a total number of 36.

A diagrammatic sketch of the experimental machine is given in Fig. 7. The two main brushes are represented by B, B′, and the exciting coil of the stator by S. The brushes were of "Le

Digitized by Google

Carbone" make, "Z" quality, and had a contact surface of 10×26 mm. The test brushes b, b', which had a width about equal to the insulation, were used throughout to measure the voltage E_r. In order to obtain the same value for the induced E.M.F. in the short-circuited coils for different rotor speeds, all that is necessary is to keep the value E_r/n constant, n being the revolutions of the rotor per minute. Since the width of one brush is equal to that of two segments, the number of short-circuited turns in series between the tips of one brush is a lways $S_K = 4$, or generally $S_K = \frac{b}{\beta} \cdot \frac{P}{a} \cdot \frac{N}{2K}$.

where K = number of commutator segments,
b = width of brush,
β = width of commutator segment.

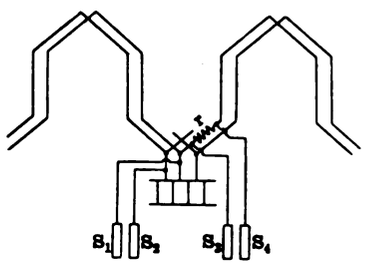

FIG. 11.

The effective E.M.F. induced in one short-circuited coil is $E_1 = \pi \sqrt{2} c \Phi_{max.} 10^{-8}$ volt, and consequently the total E.M.F. induced in the coils between the tips of one brush is

$$S_K E_1 = E = \frac{\pi}{\sqrt{2}} \cdot \frac{N}{K} \cdot \frac{b}{\beta} \cdot \frac{p}{a} \cdot c \cdot \phi_{max.} 10^{-8} \text{ volt.}$$

Since the E.M.F. measured at the search brushes was $E_r = \frac{1}{\sqrt{2}} \cdot \frac{pn}{a60} \cdot N\phi_{max.} 10^{-8}$, it follows that $E = \frac{E_r}{n} \cdot k$, where k is a constant and equal to

$$\frac{60 \cdot c \cdot \pi \cdot b}{\beta K}.$$

In the case under consideration c was equal to 50, and consequently $E = E_r/n \cdot 190$.

In the first instance the main brushes were removed from the commutator, and for a constant value of E_r/n the rotor was driven at different speeds by means of an auxiliary motor. For

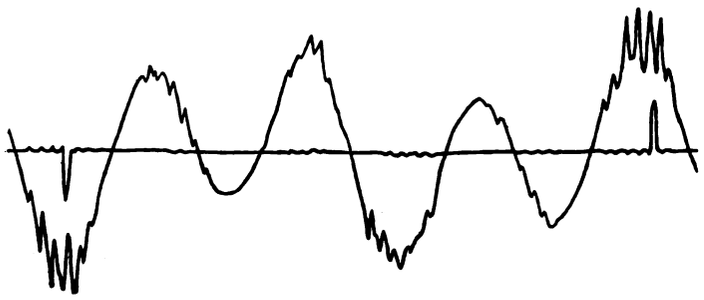

FIG. 12.

each speed the watts supplied to the exciting winding were measured, these values giving the iron losses, and the copper losses in the exciting coil. The main brushes were placed on the commutator and in the neutral zone, the position of which had been previously carefully determined. The watts supplied to the exciting winding were measured as before, E_r/n having the same value. The differences between these readings gave values for the watts lost due to the circulating currents in the short-circuited coils after the necessary correction had been made for the stator copper losses.

The short-circuited coils lie in a plane to which the exciting axis is perpendicular, and consequently these circulating currents can exert no torque effects.

In order to eliminate the effects of change in temperature of the brush over the range of values for E_r/n and the consequent changes in contact resistance, it was found necessary to provide the brushes with a number of layers of metal foil pressed on the edges of the brush and as near to the commutator as possible. By this means the heat generated could escape more readily, so that expansion and consequent lifting of parts of the brush from the commutator were avoided. With the adoption of this device it was found that any small

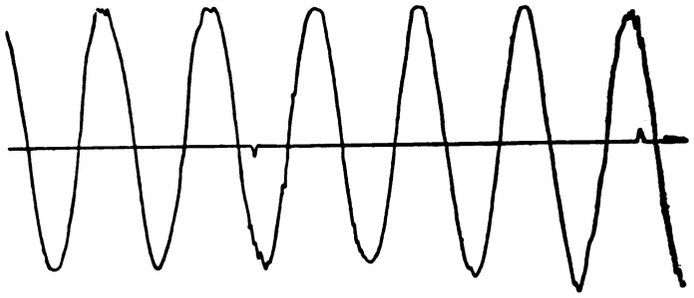

FIG. 13.

temperature changes which took place within the limits of the experiments did not affect the readings. The condition of the commutator surface was apt to change somewhat, and it was found convenient to have a cleaning pad continually rubbing on the commutator.

The values for the losses obtained are plotted in Fig. 8 as a function of the speed for the four different values of E_r/n

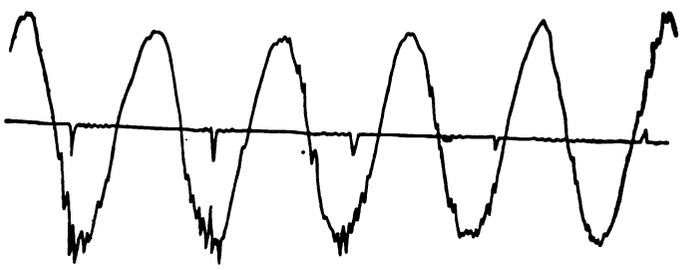

FIG. 14.

= 0·024, 0·022, 0·02 and 0·018, corresponding to effective values for the short-circuit E.M.F. E equal to 4·5, 4·18, 3·8 and 3·42 volts. At a voltage of 4·5 sparking was apt to take place. These curves clearly demonstrate the effect of the speed. Readings for very low speeds could not be obtained on account of the swinging of the instruments and general instability of the working. The losses assume practically a constant value

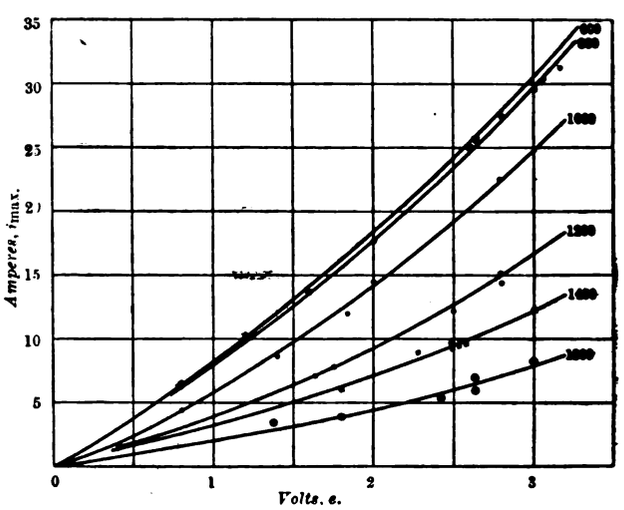

FIG. 15.—CURVES TAKEN FROM OSCILLOGRAMS SHOWING MAXIMUM VALUES OF SHORT-CIRCUIT CURRENTS AND CORRESPONDING VALUES OF e.

below a speed of 800, while for higher speeds they fall rapidly to low values. The calculated curves do not fall so quickly as those derived experimentally. This is due, as shown, partly to the fact that the contact resistance varies with the current-density, and therefore both curves cannot be directly compared,

Digitized by Google

since it is not known what value of R_u should be taken in the calculation.

Experimental results showing the *relation between brush contact resistance and current-density* have already been given by various investigators, the brush generally being placed on a slip-ring. In order to investigate the effect of the discontinuous contact surface of a commutator, the authors carried out experiments under the working conditions. The brushes were placed on the commutator, which was short-circuited by a heavy band of copper wire. A current at 50 periods was passed through the brushes, and the pressure between the brushes measured. Since the copper band over the commutator had an exceedingly small resistance, the drop of pressure in this part of the circuit was negligible, and the pressure between the brushes practically equal to the drop at the brush surfaces. By measuring effective values of current and pressure, we obtain the relation between the effective current-density and the effective resistance. The specific resistance is the ratio of the voltage drop $\triangle p$ at one brush to the current-density. It is interesting to compare the instantaneous values of the current-density and voltage drop. For this purpose calibrated oscillograms were taken. The results are represented by curves in Fig. 9. Curves A, B and C show the effective voltage drop as a function of the effective current-density for one brush for speeds of 1,900, 1,200 and 800 revs. per min., and they have the same character as those taken with direct current. Curves A′, B′ and C′ show the instantaneous values of the voltage drop as a function of the instantaneous current-densities for the same speeds as before. These curves are similar to those obtained when the brushes are placed on slip-rings,* but while with slip-rings the speed has practically no influence, this is not the case with a commutator. The contact resistance increases for a given current-density with the speed, which may be due to the insulating layers between the commutator segments. Fig. 10 shows how the resistance changes with the speed, the effective current-density being 15 amperes per square centimetre.

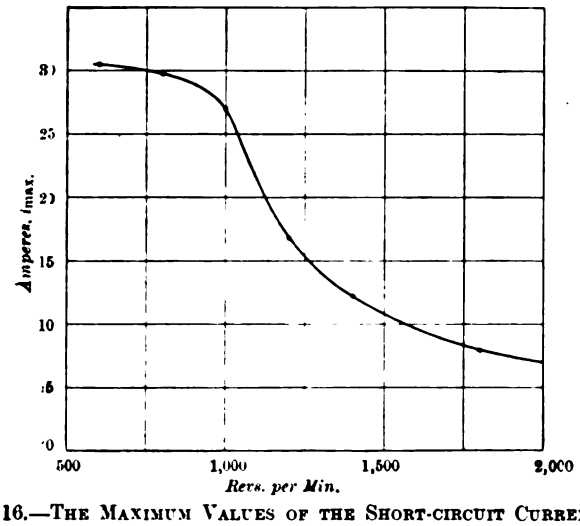

FIG. 16.—THE MAXIMUM VALUES OF THE SHORT-CIRCUIT CURRENT FOR A VALUE OF THE INDUCED VOLTAGE $e=3$.

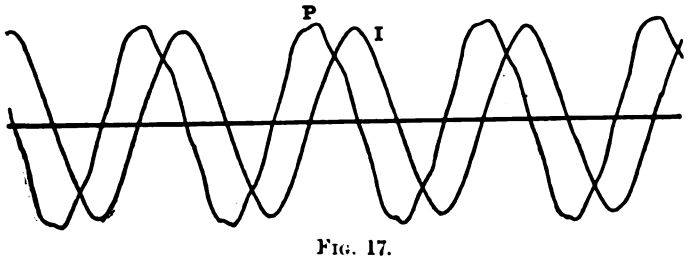

FIG. 17.

OSCILLOGRAPH RECORDS.

Oscillograms have been taken which exemplify extremely clearly the conditions prevailing during a short-circuit period. By means of slip-rings and a small non-inductive resistance it was possible to obtain records of the E.M.F. induced in any armature coil under consideration, and of the current produced in it so soon as it was short-circuited by the brush. The arrangement was as shown in Fig. 11. Two adjacent segments were connected to two slip-rings, S_1 and S_2, on which brushes were lying, the brushes being connected to the oscillograph, which in this case recorded the pressure between these segments. A small resistance, r, was placed in one coil, and its ends connected to two other slip-rings, S_3 and S_4, these being in connection with the second strip of the oscillograph. This gave a record of the short-circuit current. Figs. 12, 13 and 14 show examples of the curves of pressure and current obtained under different conditions. The current is only recorded at the moment when the coil is under short-circuit. The pressure wave has a compound form, since it is the induced E.M.F. in a coil which rotates in an alternating field. There is a main wave whose form and strength depend upon the main flux and the speed, and the ripples are due to the mutual induction of the short-circuit currents in the neighbouring coils. At the moment when the coil under consideration is in short-circuit the pressure measured at its segments falls rapidly, being only equal to the drop between the brush and the two segments. The instantaneous value of the induced voltage at the moment of short-circuit can, therefore, only be estimated by drawing a mean curve between the peaks. The scale of the oscillograms was taken, and for the different values of the instantaneous induced E.M.F.s the corresponding maxima of the short-circuit currents $i_{max.}$ were measured. These are shown in Fig. 15, $i_{max.}$ being plotted as a function of e for six different speeds, and it may be seen that $i_{max.}$ decreases rapidly as the speed increases. This decrease is shown clearly in Fig. 16, where for a constant value of $e=3$ volts the maximum values of the short-circuit currents are plotted as a function of the speed. This curve has quite the same character as those obtained for the losses, this

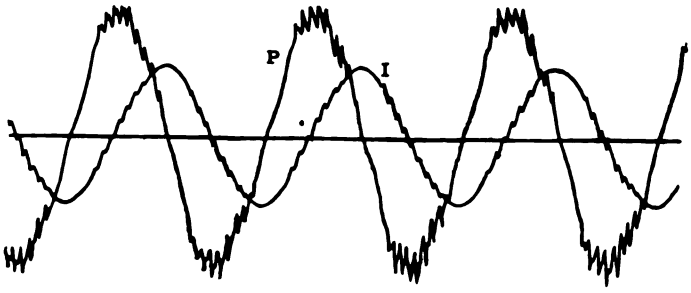

FIG. 18.

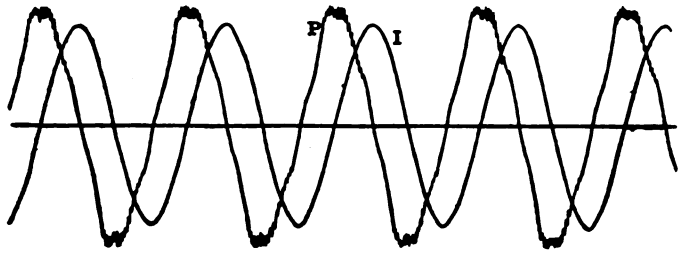

FIG. 19.

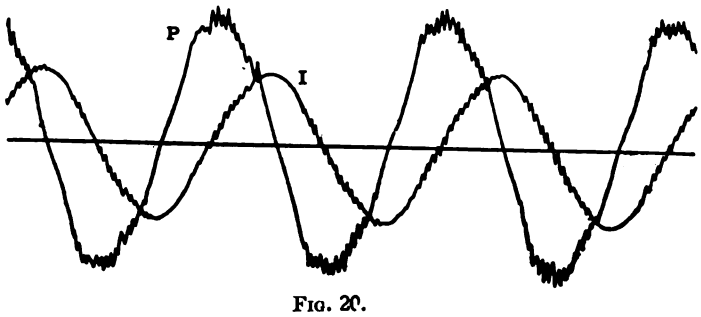

FIG. 20.

* Arnold, "Die Gleichstrommaschine," Bd. 1., S. 348.

Digitized by Google

fact again affording evidence of the correctness of the loss curves.

It is also interesting to note the *effect of the short-circuit currents upon the primary current and voltage*. This is shown in the oscillograms 17, 18, 19 and 20. The first gives the pressure and current of the exciting winding when no brush is on the commutator. The current is lagging something less than 90 deg. behind the pressure. The second shows the same relations when one brush is on the commutator, the value of E_s/n being 0·022 or E=4,2 volts, and the speed 760. There are very distinct ripples in both current and pressure waves, this being due to the flux pulsations produced by the short-circuit currents. The ripples have their maxima approximately when the pressure is a maximum. Fig. 19 shows the curves for the same value of e, but for a speed of 1,900. The ripples in the current curve have disappeared, while those in the pressure curve still exist, but to a much smaller extent than in the previous case. Finally, Fig. 20 shows the conditions where there are two brushes on the commutator, the speed being 1,250.

The authors wish to express their thanks to Prof. Arnold for placing at their disposal the apparatus in the Electrotechnical Institute, Karlsruhe in Baden.

ELECTRICAL EXHIBITS AT THE BRUSSELS INTERNATIONAL EXHIBITION.

The Brussels Exhibition will perhaps be more notable for the excellence of its engineering exhibits than for any other reason, and it is not surprising that electricity should play an important part in introducing a considerable element of novelty in much of the machinery and apparatus displayed. There are many circumstances which render the exhibition particularly convenient from the manufacturers' and buyers' point of view, its central position and easy accessibility from all parts of Europe being an advantage not easily over-estimated. There is little doubt, moreover, that the arrangements which the authorities have made are infinitely better than are usually expected in large exhibitions, and most of the exhibitors admit that the allotments and preparations for their plant have been carried out with the utmost fairness and completeness. The Exhibition, too, has, in some cases for the first time, come under the direct authorisation of the various States, and the importance of this will have been appreciated particularly by the British exhibitors, while the magnificent arrangement of the German section is a monument to the value of the practical interest of an energetic government.

Except for the German exhibits, practically all the engineering plant and machinery are situated in one large machinery hall consisting of five bays, of which the end one is reserved for a complete battery of boilers for supplying steam to the generators. The German machinery is for the most part displayed in special departments of the German section, and is self-contained in every way, being totally independent of the main exhibition, even for the supply of electrical power.

In the large machinery hall most of the generators used for supplying electrical power to the machines and for all purposes for the exhibition are located, steam being delivered from the boilers in the adjoining bay through pipes laid for the most part underground. The boilers, of which there are 10, were all manufactured by De Neaver and are fitted with underfeed mechanical stokers. The conveying plant for automatically delivering the coal from the outside supply to the boilers, and for taking the ashes away and depositing them where required, is verying eniously arranged and is electrically operated. The coal bunkers are some distance behind the boilers and are let into the ground with the mouth flush with the ground level. The coal is tipped into them and is dropped, as required, into the buckets of the conveyor beneath by means of sloping shoots, and the conveyor rises above the ground, when clear of the bunkers, to the level of the top of the boilers. The buckets then proceed parallel to the axes of the boilers until level with the front, when they turn at right angles and run the whole length, descending at the other end, and returning underneath the floor level in a subterranean passage, so that the ashes from the boilers may be tipped into them. The buckets then rise to just underneath the coal delivery buckets, thus forming a complete chain to the coal bunkers, the ashes being discharged by means of a tip and shoot. The whole gear is driven by an electric motor, and in spite of the many turns, works extremely well, swivelling buckets being used, as is, of course, necessary on account of the corners. There are four forced-draught fans driven by electric motors in the chamber underneath the boilers, and these deliver air into a main pipe, which, by means of valves, discharges into the furnaces as required.

Continuous current is supplied for the exhibition at 230 and 460 volts, while there is also a 460 volt alternating-current supply available. Current is taken to the main switchboard from the various generating sets which form part of the exhibits, and this switchboard is erected on a raised platform at the top of the machinery bays, extending the width of two of them. Alongside the switchboard, and extending the width of the remaining bays, are two large balancers, each machine running at 230 volts for supplying this pressure between the inners of a three-wire system. The output of each machine is about 150 kw., while there are also two motor generators, the motor running at 5,000 volts and the generator delivering direct current at 230 volts. The switchboard is excellently fitted up and is an exhibit of the Ateliers de Construction Electrique de Charleroi. It follows the construction now almost invariably adopted on the Continent, all the meters being at the back of the board so that the dials are flush with its front.

Of the generating plant, the most important perhaps is a 1,000 kw. turbo-alternator of Messrs. Brown, Boveri, which is almost constantly running. The alternator is of the usual totally enclosed type, with an opening at the top, and its voltage is 460, three-phase. The turbine runs at 2,500 revs. per min., and the air and circulating pumps for the condenser, which is erected underneath the turbine, are driven by a three-phase motor. Part of the current from the alternator is taken through a static transformer, where the voltage is raised to 5,000, this pressure being employed to operate a 400 kw. motor-generator, which supplies direct current at 460 volts. This set runs remarkably smoothly, in spite of its high speed, 2,400 revs. per min., and the Morganite brushes work quite sparklessly. Messrs. Brown, Boveri also have an exhibit of their patent system of train lighting, which is now in operation on some trains in this country. A very compact switchboard of one panel is erected to control the alternator, transformer, and motor generator circuits, and the high-tension cables are brought to a brick chamber which has been built in the condenser pit, forming a model central station high-tension chamber.

All the other generators actually supplying current are reciprocating sets, except those in the German section described later, the majority of them being of the horizontal compound or tandem compound type, so universally adopted in Belgium, which country has hitherto been somewhat conservative in the matter of steam turbines. One of the most interesting of the reciprocating engines is a tandem machine manufactured by Bollinckx of 1,000 H.P. fitted with Bollinckx valve gear, this engine being employed for driving a Lahmeyer direct-current generator, the diameter of the armature being about 10 ft., while the same manufacturers exhibit a self-contained 100 H.P. suction gas plant, with the engine driving a small dynamo through belting, magneto ignition being employed. Among the other large generating sets is a compound, side-by-side Thirau engine, driving a 500-volt direct-current dynamo of the Compagnie Internationale d'Electricité, with an output of 500 kw. at 220 revs. per min. There is, further, a tandem compound 600 H.P. engine of Carels Frères well-known construction, employed for driving a direct-current generator, and, incidentally, it may here be mentioned that the 1,000 H.P. Diesel marine reversing engine recently built by this firm, which it was intended to exhibit, has not been erected. This will, no doubt, occasion considerable regret among many visitors who had expected to see this much talked of machine.

In view of the great interest now taken in the use of gas engines for central stations, the exhibit of Messrs. Cockerill, of Seraing, of a 2,500 H.P. horizontal gas engine, with a pair of tandem cylinders, is noteworthy. It is, however, not designed for electrical drive, and at the time of writing its erection was not completed; but it will, no doubt, be a source of attraction to electrical engineers as indicating the strides made in the construction of this class of engine. Messrs. Cockerill also show on their stand a 1,750 kw. turbo-generator of the Parsons type, with separate high and low-pressure cylinders; but at the time of writing this was not in operation.

There are a number of other generators, the most notable alternator being for 4,000 volts, 50 frequency, and 340 amperes, constructed by the Ateliers de Construction de Charleroi, and driven by a side-by-side compound steam engine of the Société de la Meuse. The same firm also exhibit a small 100 kw. six-pole, direct-current machine at 460 volts, belt driven from a tandem reciprocating engine; whilst there are several of similar type by other firms which call for no special comment.

At the Franco-British Exhibition the absence of overhead elec-

Digitized by Google

trical travelling and other cranes was generally remarked, but this will not be the case with the Brussels Exhibition. In each of the bays in the Machinery Hall there is at least one crane, and these naturally were of great service during the erection of the machinery. Except in one case they are all operated by direct current, two bare copper wires being run just above the top crane girders, and the current collected by short spring collectors. None of the travellers is of British manufacture, the chief exhibitors being the Ateliers de Construction Electrique de Charleroi, with a crane lifting 25,000kg. and Bergmann's, of Berlin, who, of course, have additional plant in the German section, while the Oerlikon Co. are the manufacturers of the only three-phase motor crane in the building.

In the bays adjoining the large generators the machine tools are located, and these form one of the most complete exhibits of the machinery section; and it is satisfactory to note that England is well represented in this particular. The adoption of electric drive is very marked, the large majority of the machines being self-contained. Messrs. J. Butler & Co., of Halifax, besides the ordinary types of machine tools, have one or two novelties worthy of note. Chief among these is a motor-driven bar cutting machine for cutting off bars from 2 in to 8 in.. in diameter. The bar is clamped in a vice close to the tool (two vices being employed for long bars), and the tool is fixed in a disc which revolves in a large bearing forming part of the body of the machine. The tool works gradually toward the centre by means of a feeding arrangement, and a small pump is employed to provide the soap and water or other lubricant, so that the attendant does not have to look after this. This machine is specially adopted for motor drive, since a variable speed motor may be employed with a constant gear ratio. The speed of cutting can be increased for small bars, and, as the centre is approached, with large bars.

(To be Concluded.)

NEW GENERATING STATION OF THE WESTMINSTER ELECTRIC SUPPLY CORPORATION.

(Concluded from page 226.)

In our last issue we described the arrangements for obtaining condensing water from the river, and also the strainers which have been installed. Fig. 5, herewith, gives a view of the latter. The Bailey & Jackson rotary strainers will be noticed on the right-hand side of this illustration, and the suction boxes containing the grids for preventing large foreign matter entering the pumps in the upper left-hand corner.

In connection with the method—briefly referred to last week—for preventing air pockets in the condensing water pipes, it may be explained that separate 1½ in. vacuum pipes are led from all the high points of this pipe-work into a vacuum tank on the roof of the station and at a height of 70 ft. above the condensers. To this tank the vacuum pump previously mentioned is connected. Each vacuum pipe thus forms a barometric leg in which the water rises, and all air is collected in the vacuum tank. To prevent any water from accumulating in this tank a barometric drain pipe is provided. The arrangement, which is due to Messrs. Kennedy & Jenkin, is of considerable interest.

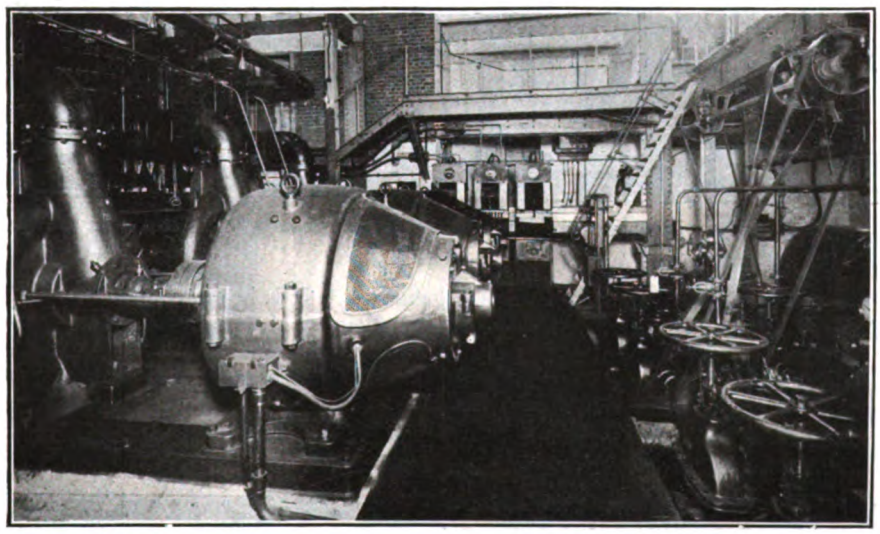

Fig. 5.—View of Strainers and Refs Roturbo Pumps.

The vertical-spindle electrically-driven turbine pumps supplied by Messrs. W. H. Allen, Son & Co. afford an interesting example of the advance made in recent years in the application of this class of pump to power station work. From considerations of practical utility, the arrangement of the pump and motor, with the axis of rotation vertical and direct-coupled, is one that obviously has much to commend it, as it enables the pump to be placed at as low a level as may be desired, thus avoiding the troubles so often encountered when a centrifugal pump has to work with a considerable lift on the suction side. The electric motor can also be placed on the engine or pump room floor level in an easily accessible position and well away from all risk of damage from water, &c.

In the early days of electrical driving this arrangement of the plant was attempted, but met with little success owing chiefly to difficulties experienced with the balancing of the vertical forces and from objectionable shaft vibrations, also difficulties in connection with bearings. It is interesting, however, to note that, as a result of the much greater experience which has now been obtained in the running of shafts at high speeds, and the better knowledge available in the design of both shafting and bearings, the old difficulties have completely disappeared, with the result that this arrangement of the plant is destined to become one of very wide application.

In the present instance the plant consists of three pumps with motors and switchgear, the complete equipment having been designed and manufactured by Messrs. W. H. Allen, Son & Co. at their works at Bedford. The smallest of the three pumps is a hot-water pump capable of delivering 100 gallons per minute against a head of 45 ft., with an efficiency of 60 per cent. when running at 1,600 revs. per min. It is placed in the basement of the building below the water level of the hot-water sump, and is direct-coupled through a length of about 12 ft. of shafting to an electric motor of 2·8 kw. situated on the engine-room floor level. The motor armature runs entirely in ball bearings, the top-most bearing being of the ball-thrust type and carrying the weight of the armature. At about the floor level and within the motor casing is a flexible shaft coupling, which is capable of transmitting rotational forces only, or, in other words, permits of 5 deg. of relative freedom. Situated immediately below this coupling, in an extension of the motor housing, is a ball-thrust bearing, designed to carry the weight of the shafting and the pump impeller. The various lengths of shafting are connected by ordinary flange couplings and supported laterally by ordinary white metal bearings in halves.

The pump is of the turbine type, having one impeller and one set of diffuser blades, both of special bronze. The spindle is of steel and encased in bronze liners, and the bearings of white metal. An automatic hydraulic balancing device is employed to carry the weight of the rotating parts of the pump and a part of the weight of the vertical shafting. The pump casing is of cast iron and contains the usual collecting chamber and suction and discharge branches all in one casting. The whole of the interior of the pump is easily accessible for inspection and repair without disturbing the fixing of the casings.

Digitized by Google

The second pump is a well-water pump designed to deliver 100 gallons per minute against a head of 100 ft., with an efficiency of 61 per cent. when running at 1,600 revs. per min. This pump is of the two-stage turbine type, and is situated in the basement, its motor of 5·6 kw. being on the boiler-room floor level. The design of the motor, shafting and bearings is similar to that described above, the length of shafting between pump and motor being about 10 ft. The pump casing is of cast iron, made in sections accurately registered together and held by tie bolts through the flanges of the outer sections. In the upper part of the casing is a water-cooled collar-thrust bearing, which is provided for registering accurately the position of the impellers in the casing.

The third and most interesting pump of the series is a centrifugal boiler feed pump, of the six-stage turbine type, the general design and arrangement being very similar to that of the pump last described, excepting for the greater number of impellers. It is designed to deliver 100 gallons of water per minute against a head of 485 ft. when running at 2,200 revs. per min. and with an efficiency of 61 per cent. This pump, which is illustrated in Figs. 8 and 9, is direct-coupled, as in the previous cases, to a 22·8 kw. shunt-wound motor through a length of 8 ft. of shafting. It is interesting to record that this set on test gave an efficiency of 63 per cent. under the specified conditions. The pump stands upon a foundation block about 33 in. above the floor of the basement, and the motor stands on the pump room floor level.

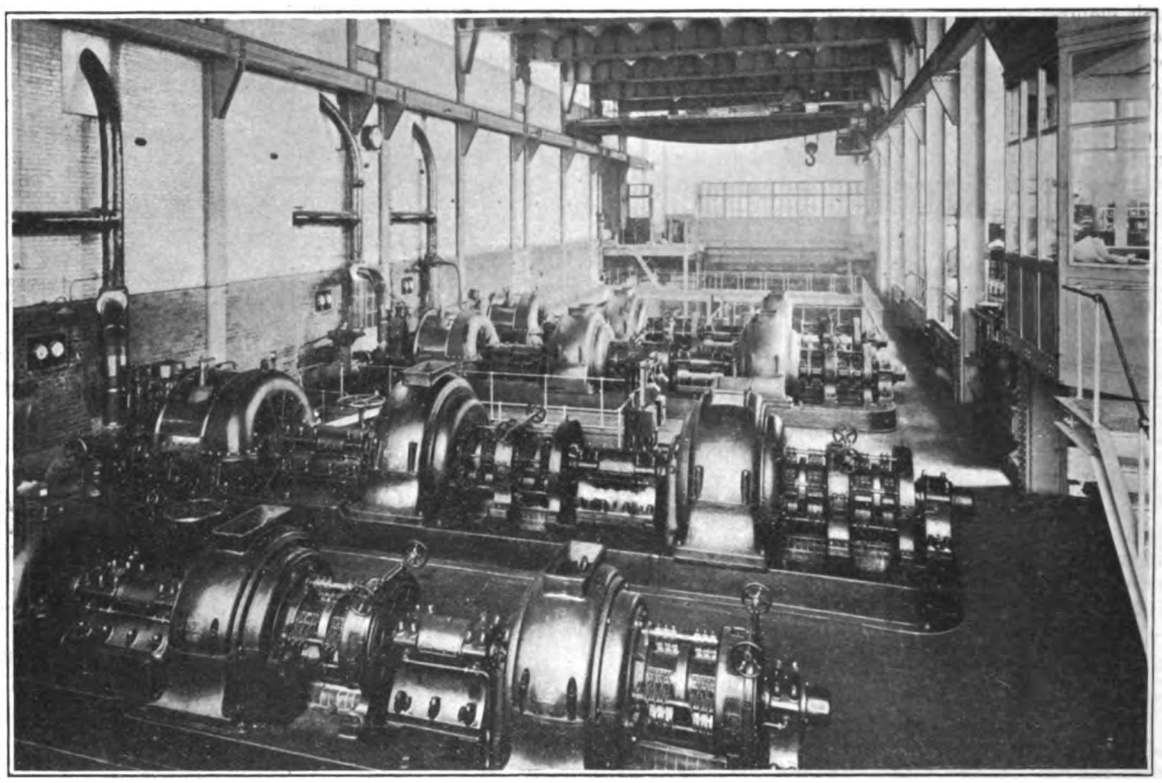

Fig. 6.—Engine Room at the Horseferry-road Station of the Westminster Electric Supply Corporation.

Pipework.—The arrangement of the steam pipes can be seen from Fig. 3 in our last issue. It may be mentioned that the main piping consists of 7 in. weldless steel, the flanges being riveted on; whilst in the case of smaller steam pipes the flanges are screwed on. A Babcock & Wilcox separator, 20 in. in diameter by approximately 2 ft. 9 in. overall, is provided in the steam main, and Hopkinson-Ferranti valves with cast steel

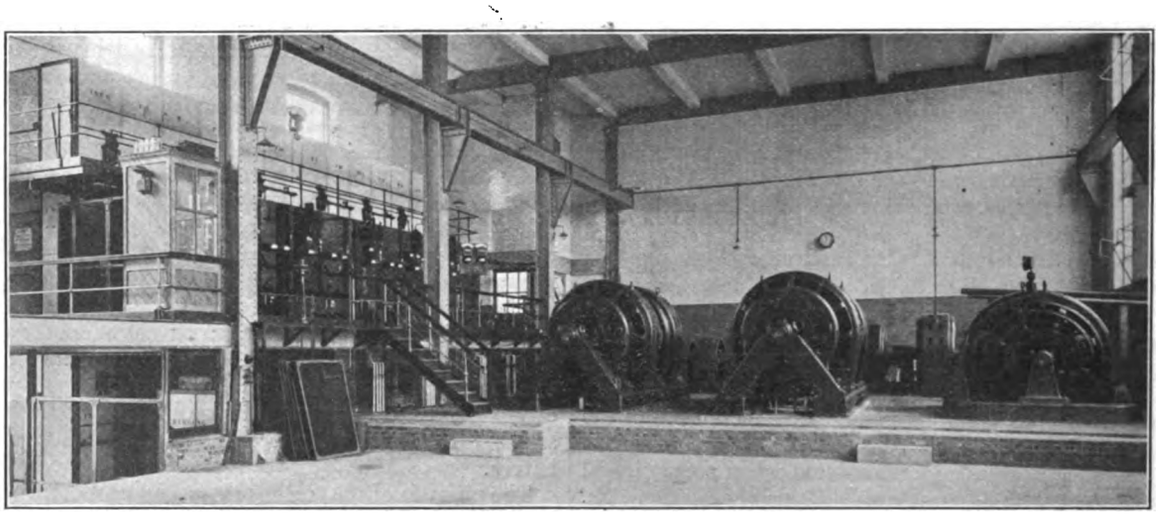

Fig. 7.—View of Motor-generator Room and High and Low-tension Switchboards.

Digitized by Google

bodies and nickel alloy working parts are employed. The branches to the balancers and generating sets are of 4 in. and 6 in. diameter respectively.

The atmospheric exhaust pipes from the 300 kw. balancers are 10 in. in diameter, and those of the 1,000 kw. sets 14 in. in diameter. The main atmospheric exhaust pipe, as will be noticed from Fig. 3, referred to above, increases from 14 in. to 24 in.

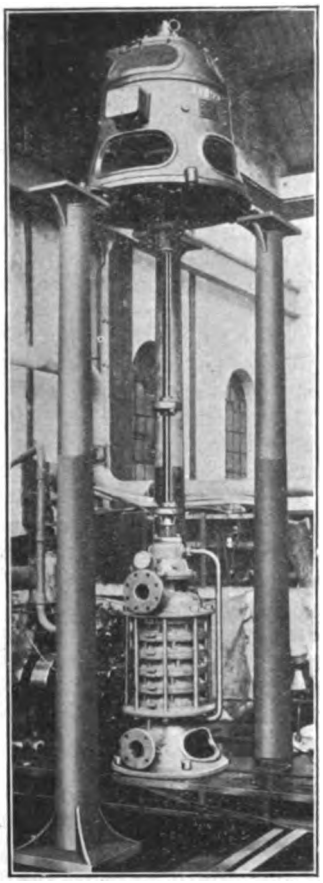

FIG. 8.—ELECTRICALLY-DRIVEN SIX STAGE CENTRIFUGAL BOILER FEED PUMP ON TEST PLATE OF MESSRS. ALLEN, SON & CO.

Engine Room Plant.—The main generating plant comprises three 1,000 kw. turbines, supplied by Messrs. Howden Bros., each coupled to two 500 kw. continuous-current generators (1,220—1,088 amperes at 410—460 volts) of Messrs. Siemens Bros. Dynamo Works' manufacture. In addition there are two 300 kw. steam balancers of the same type as the main

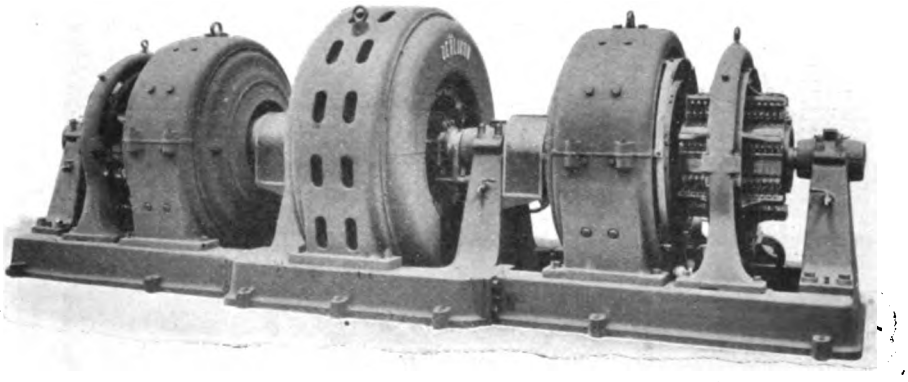

FIG. 10.—OERLIKON MOTOR-GENERATOR.

sets; each driving two 150 kw. generators at 200—230 volts pressure, whilst the dynamos for supplying the two outer conductors of the three-wire system run, as stated above, at 410—460 volts. A view of the engine room, with one of the balancers in the foreground, is given in Fig. 6. The turbines are of the Zoelly impulse type, and the larger sets run at 1,850 revs. per min., and the steam consumption guaranteed by the manufacturers, with 150 deg. superheat and a 28½ in. vacuum (barometer 30 in.), was as follows:—

Full load.	¾ load.	½ load.	¼ load.
17·1 ...	18·4 ...	20·8 ...	27·4 lb. per kw.-hour.

The corresponding figures for the 300 kw. plant are:—

19·56 ... 21·75 ... 25·75 ... 36·75 lb. per kw.-hour.

In each case the plant can take an overload of 25 per cent. for half-an-hour and 40 per cent. for 3 minutes. The turbines were also specified to give normal full load when running non-condensing and exhausting direct to atmosphere.

As mentioned above, each turbine is direct coupled to two dynamos in tandem, this arrangement being considered by the

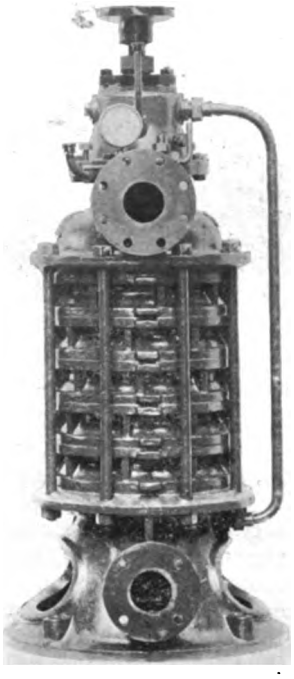

FIG. 9.—SIX-STAGE CENTRIFUGAL BOILER FEED PUMP OF MESSRS. ALLEN, SON & CO.

engineers to be more reliable at the present time than single generators of double output. Particular attention has been paid by Messrs. Siemens to compensating the armature reaction, two commutating poles, as well as a distributed compensating winding on the main poles, being provided. We noticed when we visited the station last week that the carbon brushes which are used ran sparklessly. As will be seen from Fig. 6, each commutator is divided into two distinct parts, and the connections between the two parts are arranged to act as a fan for ventilating the interior of the commutators. The machines themselves are ventilated by fans on the armature shaft, the hot air being discharged through an opening at the top of the frame.

The machines are self-excited and the pressure is regulated by hand, an adjustable rheostat being inserted in the field circuits.

The condensers, which are situated beneath the turbines, are of the "Contraflo" type, and were supplied by Messrs. Willans & Robinson. The air pumps (Edwards type) are electrically driven, and we may here mention that all electric motors in the station, with the exception of three pump motors of Messrs. Allen, Son & Co.'s manufacture, have been supplied by the Rees Roturbo Co.

Digitized by Google

Careful provision has been made for keeping account of all water used and for ascertaining the cause of any undue consumption. Lea recorders are employed for the air pump discharge and for the make up water; a Kennedy meter measures the feed water and a Venturi meter enables the amount of condensing water to be ascertained. Three "Aero" recorders (Stone's patent) indicate the level of the water in the storage tank on the roof, in the "treated water" tank and in the hot well respectively. The "make up" water is obtained from a well in the station, the public water supply being used only as a stand-by.

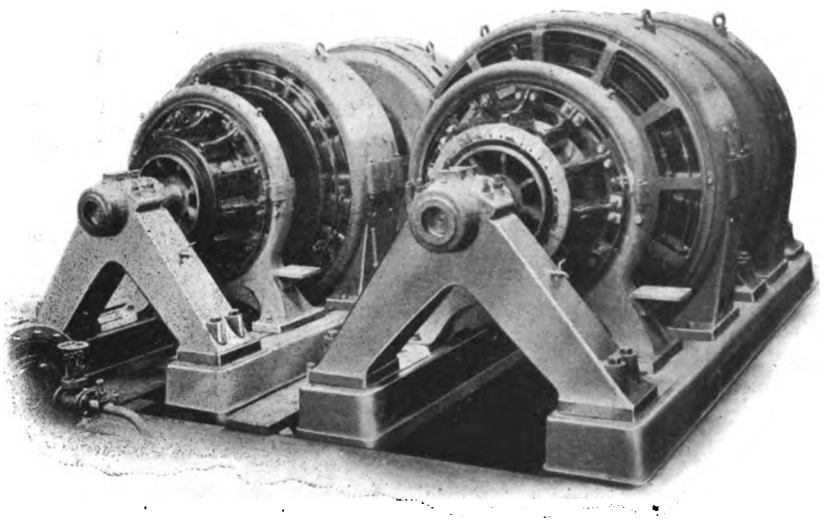

FIG. 11.—VIEW SHOWING D.C. ENDS OF OERLIKON MOTOR-GENERATORS.

A 25-ton electric crane by Messrs. Marshall, Fleming & Co., of Motherwell, spans the engine room, and one of similar size is installed in the motor-generator room.

Among the accessory plant, attention may be called to an electrically-driven Lacy-Hulbert air compressor, which has been found very convenient for cleaning the generators, economiser tubes, &c.

boosters have been installed in the motor-generator room. The pressure of these boosters is regulated by hand from the main switchboard gallery in the engine room. The five end cells of each battery can also be used for regulating purposes.

As continuous current is supplied from the Horseferry-road station on the three-wire system at a declared pressure of 400 volts across the outers, it is evident that the batteries act as a stand-by; but, of course, they would usually only be capable of dealing with a small part of the load. In this connection it may be mentioned that the Houses of Parliament are supplied from this station, a special panel on the switchboard controlling the supply. The batteries also serve as a stand-by for the various motors driving the auxiliary plant in the station.

Motor-Generators.—Undoubtedly one of the most interesting features of the new station of the Westminster Electric Supply Corpn. is the large motor-generator room, which is situated above the main engine room, and is of about the same size as the latter. Whereas, however, provision has been made for installing steam plant to a total capacity of 6,600 kw., the motor-generator room can accommodate, if ever required, transforming plant to the extent of 15,000 kw.

At present two 1,000 kw. Oerlikon motor-generators and a 500 kw. machine of the same type for balancing purposes have been installed, together with a 500 kw. B.T.-H. motor-generator which was used at the Millbank-street station and has been transferred to the new station. Electrical energy is supplied to this plant at 6,000 volts 50 cycles from the Grove-road station of the Central Electric Supply Co. The motor-generators are operated in parallel with the main steam plant installed on the ground floor, so as to obtain the most economical results.

The motor-generators can stand an overload of 25 per cent. for half an hour and a 40 per cent. overload for three minutes, whilst they run sparklessly from no load to 40 per cent. overload without shifting the brushes. They are also so built

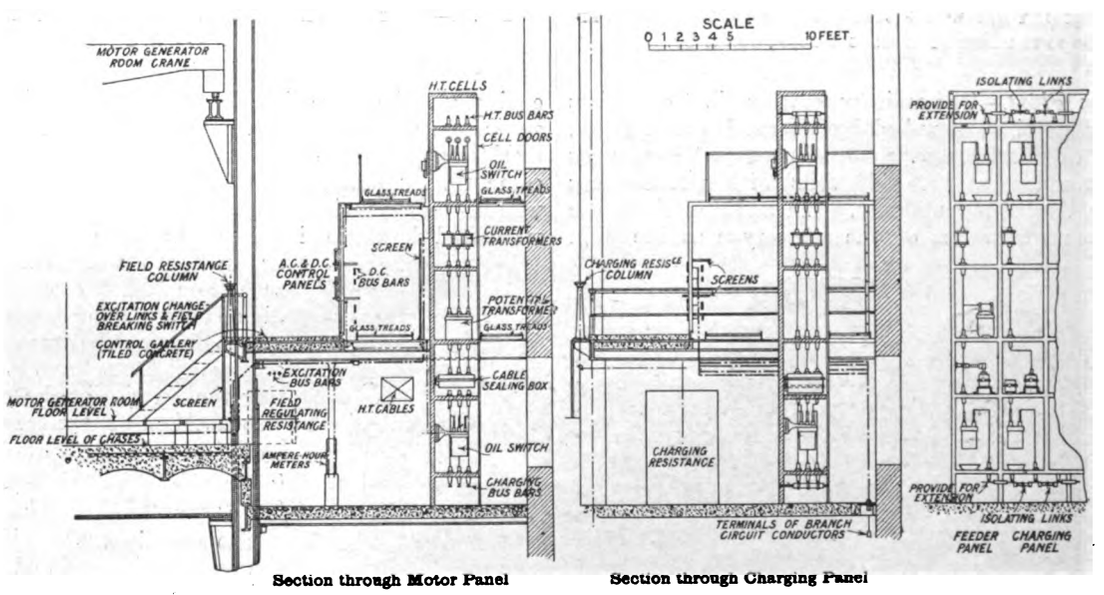

FIG. 12.—SECTIONS THROUGH H.T. SWITCHBOARD.

Batteries.—Two storage batteries, each containing 100 cells, are installed in a room adjacent to the motor-generator room. The normal capacity of the batteries, which have been supplied by the Tudor Accumulator Co., is 2,100 ampere-hours on the one-hour rate, and they are capable of discharging at 1,200 amperes for two hours, or 950 amperes for three hours. For charging and discharging the cells in each battery two B.T.-H. that when running at normal speed they can be switched on to a short-circuited system (due to failure of the supply or defective cables). This they have to do with a current equal to 40 per cent. overload and about 20 volts to start with, the pressure to be raised by regulation (separate excitation) from this level up to the normal. Even under these conditions the machines have to remain practically sparkless.

Digitized by Google

In the view of the motor-generator room given in Fig. 7 the two 1,000 kw. Oerlikon generators will be noticed, whilst the machine on the right-hand side of the illustration is the 500 kw. B.T.-H. motor-generator. In the background the balancer is just discernible; whilst Figs. 10 and 11 show further views of the Oerlikon machines.

The direct-current Oerlikon generators are of the auxiliary pole type, and the commutator is equipped with shrink rings of a design similar to that adopted with most Oerlikon turbo-generators. The Λ spread bearings have been adopted to obtain the greatest possible stability of the machine and also to give easy and comfortable access to the commutator.

The three-phase motors are equipped with the well-known Oerlikon pole type of rotary resistances, which represent a specially strong mechanical job and permit very gradual and steady starting up without any outside apparatus. The stator coils are embedded in seamless micanite tubes filled with compound, as described in our issue of August 30, 1907, and the rotors are bar-wound.

Switchgear.—This comprises a low-tension three-wire continuous-current switchboard in the engine room and high and low-tension switchboards in the motor-generator room. Practically the whole of the control, however, is carried out from the switch gallery in the engine room, the switches and instruments for the main generators, balancers, batteries, boosters and low-tension feeders being located on this switchboard.

The arrangement of this board is on standard lines, but attention may be called to the fact that aluminium rod has been largely used for the connections behind the panels, the leads to the generators being also of aluminium rod. This allows of a very neat arrangement, and minimises the risk of fire. Duplicate 'bus bars are provided, so that the pressure on individual feeders can be varied; whilst section switches allow of each 'bus bar being divided into two independent halves.

From this switchboard, which is on a gallery at one side of the engine room, as will be seen from Fig. 6, connections are run to the low-tension switchboard in the motor-generator room, a view of the high and low-tension boards installed in that room being given in Fig. 7. The high-tension gear is of the standard B.T.-H. type, the British Thomson-Houston Co. being the contractors for the whole of the switchgear. Provision is made for the necessary switching in connection with the high-tension feeders from Grove-road station and the three-phase induction motors of the motor-generators. The switches are enclosed in fire and arc-proof cells of the usual construction. A section through the high-tension switchgear is given in Fig. 12.

In conclusion, we desire to express our indebtedness to Messrs. Kennedy & Jenkin, the consulting engineers to the Westminster Electric Supply Corpn., for giving us facilities for obtaining the information contained in this article, and to Mr. G. Horley, engineer at the Horseferry-road station, for kindly explaining the various features of the plant.

THE HELSBY WIRELESS TELEGRAPH AND TELEPHONE SYSTEMS.

The wireless apparatus which this company has installed in its experimental station at the Crystal Palace consists of a simple and practical form of spark station, with, in addition, a pair of portable earth-conduction sets for telegraphy and telephony. The two systems are absolutely independent of one another, so that it is possible to use the earth-conduction telegraph or telephone for local communications in the immediate neighbourhood of the spark station.

The details of the instruments have evidently been very carefully thought out, with the result that their design is very workmanlike and their operation exceedingly simple and rapid. In the spark station, for instance, the change over from sending to receiving, or vice versa, is done by a single master switch, which controls five separate circuits simultaneously, and the apparatus is built up in sections, each of which is completely

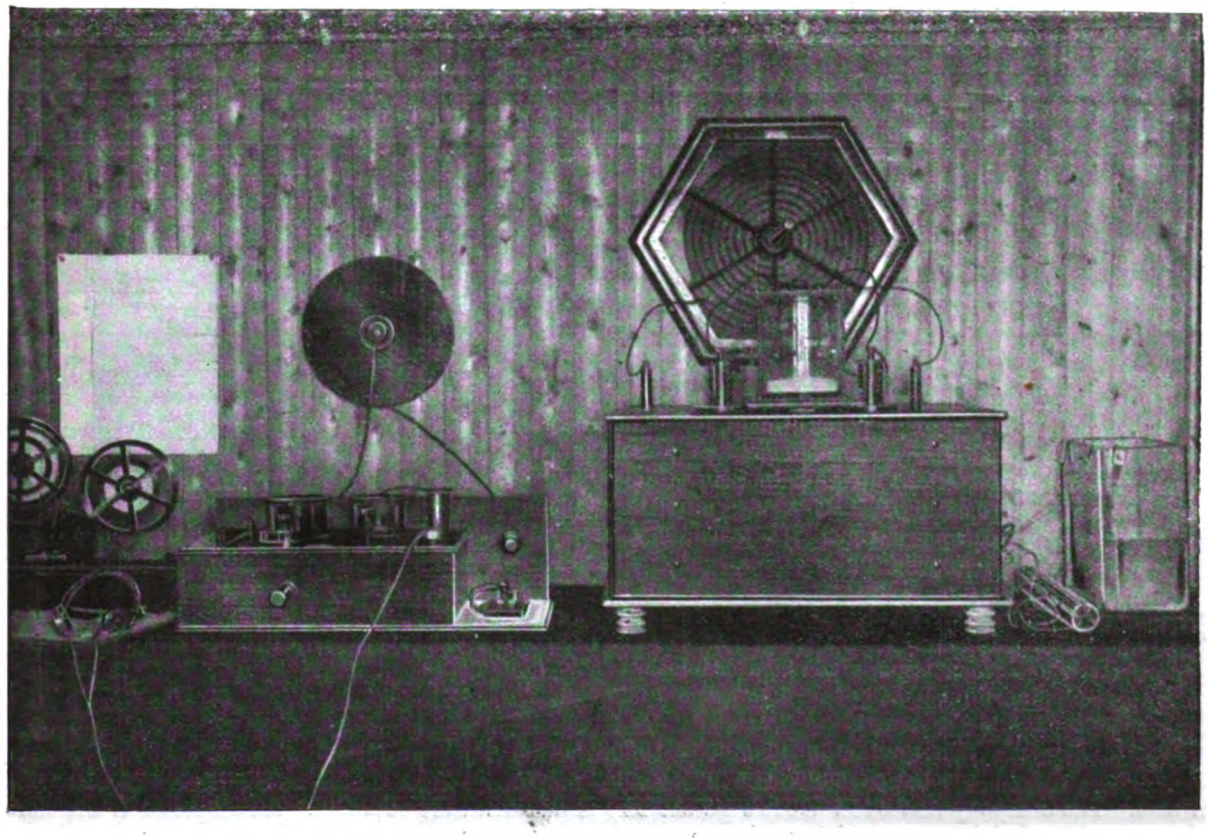

FIG. 1.—COMPLETE SPARK STATION APPARATUS. LARGE SIZE.

Digitized by Google

wired, the connections between them being made by plug contacts. It is by attention to such details as this that telegraphic instruments are evolved from experimental apparatus.

The spark apparatus has a transmitting set consisting of an induction coil, or high-tension transformer, connected to an oscillating circuit containing a multiple spark-gap of original design; substantially constructed condensers of modern type, with relief gaps to prevent overloading; and a flat spiral inductance, which forms the primary of the high-frequency transformer, and transmits the electrical energy generated in the spark circuit to the aerial from which it is radiated. The spark-gap is a multiple one having four fixed and four moveable arms, the latter being attached to horizontal arms mounted on a vertical axis. The Company also owns Webb's patent for a transmitter capable of giving a very high spark rate.

The apparatus is constructed in sections of convenient size, each case being arranged to fit into its proper place on the top of the section below it. There are no external terminal screws, all connections being made by plugs and flexible. It is the careful attention which has been bestowed on these and other important details which gives the whole apparatus its exceedingly practical and commercial character.

The receiving apparatus, the main control switch and the ammeter and voltmeter for the supply circuit are all contained in, or mounted on, a single case of a size which can be placed conveniently on a small table. The receiver has a tuneable circuit capable of giving sufficient freedom from interference for practical working. Here, again, as in the transmitter, the apparatus is characterised by the simplicity of the arrangements and the absence of all temporary connections.

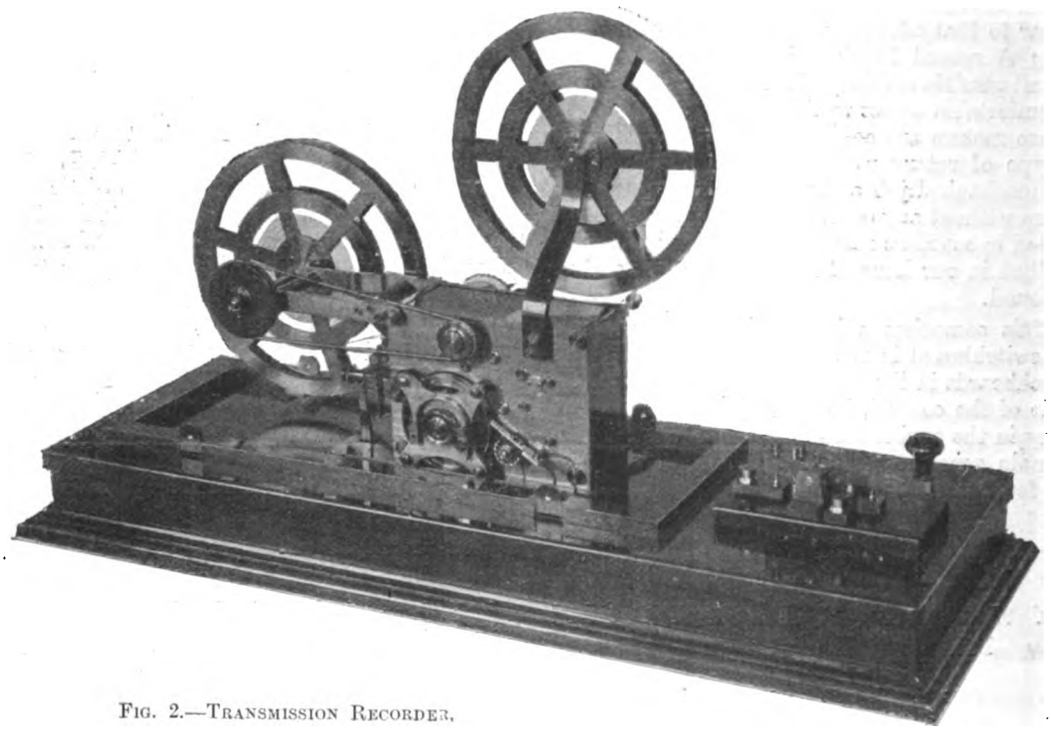

FIG. 2.—TRANSMISSION RECORDER.

An ingenious recorder forms part of the transmitting plant, and is actuated directly by the sending key, the connections being so interlocked that everything which the operator sends is automatically recorded. An inspector is therefore able to check the working of the station and ensure that the regulations of the International Convention are complied with.

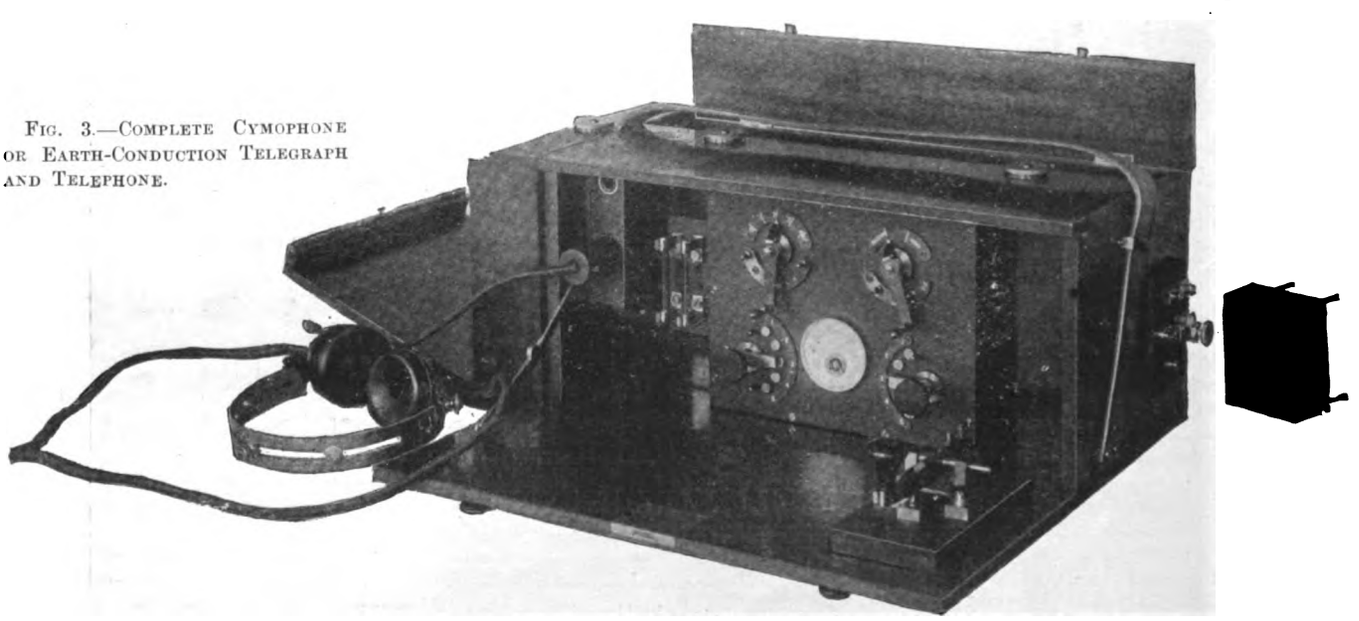

FIG. 3.—COMPLETE CYMOPHONE OR EARTH-CONDUCTION TELEGRAPH AND TELEPHONE.

The Cymophone, which is the name given to the earth-conduction system, is a very portable instrument, weighing only from 10 lb. to 15 lb. complete. Two earth connections are used at each end, the instrument being inserted in the line between

Digitized by Google

them. Speech is clearly transmitted even when the length of the base lines is only a small fraction, say $\frac{1}{15}$, of the distance between them. The power is taken from a small 6-volt accumulator, and is converted into suitable impulses in a circuit containing inductance and capacity. Telegraphy is, of course, possible with the same power and bases to considerably greater distances than telephony.

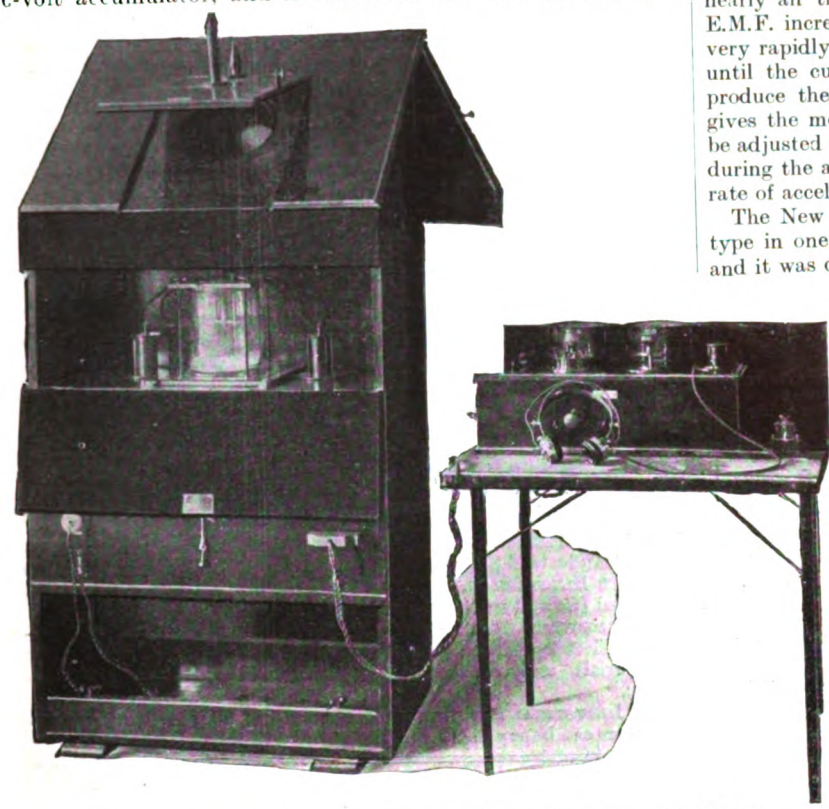

FIG. 4.—TRANSMITTER AND RECEIVER OF SPARK STATION. SHIP TYPE.

TWO-MOTOR DRIVE FOR WEB ROTARY PRINTING PRESS.*

BY S. H. SHARPSTEEN.

The drive for a web printing press may be considered in two parts, the primary or productive drive and the secondary or starting drive, which operates the press at approximately $\frac{1}{20}$th to $\frac{1}{30}$th of the production speed. The ratio of make-ready to production speed applies to newspaper work. Magazine web press production speeds are usually much lower.

When the requirements of the secondary drive for a web printing press are properly understood it is quite an easy matter to produce the desired results. For instance, a Hoe quad newspaper printing press requires approximately 30 H.P. to operate at a maximum production speed of 24,000 newspapers per hour. At such times the main shaft runs at about 200 revs. per min. The press can be threaded with paper when the mainshaft operates at 10 revs. per min., or $\frac{1}{20}$th of the maximum production speed; but $\frac{1}{30}$th of the maximum speed, or about 7 revs. per min., might be more desirable for the first running speed when the question of keeping down the paper waste due to breakage at the start is considered, and especially if the secondary drive brings the press to this speed in a jerky manner. As the power necessary to drive the press is almost in direct proportion to the speed, it would seem that a 2 H.P. motor should be large enough for the secondary drive, but the large starting friction requires a 5 H.P. motor with a normal speed of about 1,000 revs. per min. Thus it is seen that the size of the motor for the secondary drive is determined by the starting torque required.

Next, as to means for preventing rapid acceleration. Field control and multiple series connection of armatures will not here be considered, but the bridged or shunted armature, as shown in Fig. 1, offers a very satisfactory solution of the problem. The effect of the shunt resistance is to maintain the E.M.F. across the brushes at an almost constant value, which is but a fraction of the total E.M.F. The current taken from the mains remains practically constant as long as the starter handle is on the first notch. At the first instant nearly all the current goes through the motor. As its counter-E.M.F. increases, due to the increase of speed, the current falls off very rapidly and more and more goes through the shunt resistance until the current through the armature falls low enough just to produce the torque required by the press. The shunt resistance gives the motor a drooping speed torque characteristic, which can be adjusted to fit the case in hand. By keeping resistance in shunt during the acceleration period the normal speed is reached at a low rate of acceleration and without jerks.

The New York "American" installed a drive of the two-motor type in one of its press rooms in New York City some years ago, and it was claimed to be the first two-motor web press drive, using standard motors, with independent connection of the secondary drive. The secondary drive did not use the shunted armature scheme, and, therefore, it was more difficult to secure the proper start. It was started by the same controller arm that was used on the primary drive, thus requiring a controller of special design. However, there is no good reason why the secondary drive should not be started with a standard combination starter and a speed controller of the same rating as the motor, this starter being placed close beside the starter for the primary drive and having the armature bridge or shunt added. When the primary drive is in use the secondary drive may continue to run free until the speed of the press drops to a point where it would again take hold.

By the use of a first-class armature speed controller with a reasonable number of points or steps it is an easy matter to bring a press to production speed with the primary drive and control without breaking the paper after the secondary equipment has made a successful start. It is a little more economical of space to have two special motors mounted together on one base (or the secondary motor may be placed upon the primary motor, allowing the former to drive through the shaft of the primary motor) than to have the two standard motors, each on its own base and separately connected to the press.

Summing up, it may be said that a satisfactory drive for a web printing press may be made up of standard apparatus as follows: For starting, a standard motor with the usual starter and a low resistance grid or wire resistance connected across the armature, as shown in Fig. 1, should be used. The motor should be large enough to produce the initial torque without requiring excessive current. For running at the normal speed a standard motor may be used, this motor being fitted with the standard starter and armature speed controller; a field rheostat with a 10 per cent. range may be added to the equipment where desired.

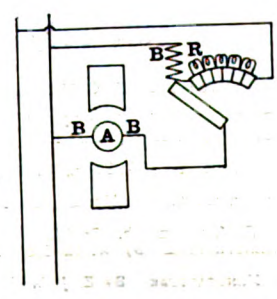

FIG. 1.—BRIDGE CONTROL.

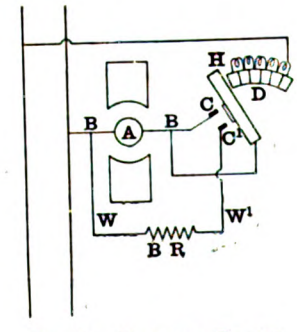

FIG. 2.—DYNAMIC BRAKE.

If a dynamic brake is wanted it may be arranged for by placing two contact pieces on the controller arm of the primary drive, as shown in Fig. 2, where A represents the armature, B and B the commutator brushes, to which are attached two wires W and W¹ connecting in the brake resistance BR, when the arm H leaves the controller dial D and is forced back upon the brake contact brushes C and C¹. An emergency stop may be had by running a push button circuit around the press, connecting the buttons in multiple and connecting the ends of the circuit to the no-voltage release coil on the starter and controller in such a manner that the coil will be short-circuited when a button is pushed and the no-voltage release allowed to act.

SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "C.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799–1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-ninth issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

STANDARDISATION OF FUSES.

It is surprising that in the course of its most excellent work the Engineering Standards Committee has not touched on the question of fuses. At present this subject is in a somewhat chaotic state. Beyond the requirement that a fuse is to blow when the current exceeds the normal value by a certain amount, nothing is very fixed. What this amount should be is left largely to individual fancy, or to the rules one may care to select. Thus the Wiring Rules of the Institution of Electrical Engineers state that no fuse shall carry more than 200 per cent. overload without fusing, whereas the Phœnix rules do not permit nearly so much overloading, allowing merely a modest 50 per cent. Since these figures are by no means limiting values, it will be admitted that in rating alone there is much latitude.

The question of rating, however, is only one of the factors involved in completely specifying a fuse. Elsewhere in our present issue will be found an abstract of a Paper on this subject read by Mr. H. W. KEFFORD before the Institution of Electrical Engineers, in which the author gives the following headings for a complete specification:—(*a*) A definition of the "marked" or "rated" current in terms of the "limiting" current; (*b*) A standard range of rated-current values and voltages; (*c*) A definition of one or more points on the "time-overload" curve of each fuse; (*d*) Regulations as to non-interchangeability, temperature rise, freedom from deterioration, and perfect operation under all conditions; and (*e*) Specifications for the standard method of carrying out short-circuit, temperature rise, and overload tests.

Mr. KEFFORD's Paper shows very clearly the present lack of uniformity. The subject is not altogether free from

Digitized by Google

difficulties. From the point of view of safety it is desirable that a fuse should not be capable of carrying two to three times its rated current for an indefinite period. On the other hand, if the overload is made small, the fuse must have a low melting point, or be run at a somewhat high temperature, which is often undesirable. Apart from any fire risk due to high temperatures, most metals tend to oxidise if so run. In all cases, however, a distinction must be drawn between large and small fuses. Although an overload of twice the rated current or more may be quite harmless in house circuits, it would be undesirable in large power circuits. Here we come also into the field of the circuit breaker, with which a time element may be combined. In the ordinary fuse there is always something of a time element, but it is doubtful whether any attempt should be made to increase this beyond a modest figure. A large mass of fusible metal is undesirable, particularly in dealing with short-circuits.

Certainly, present practice in fuses for house wiring is of an elementary kind. Such fuses can generally be renewed by anyone, being of the exposed wire type, which means that they may be replaced by any sized fuse that seems to meet the case, or even by a copper "wire" if the circuit is troublesome, thus eliminating all protection. Since branch circuits are now fairly standardised, there is no reason why a standard fuse should not be made which would be applicable to all ordinary house wiring, but it would have to be enclosed and not interchangeable. Notwithstanding Mr. KEFFORD'S opinion that it is unimportant whether a blown fuse is easily recognised or not, we think this is a point which should be borne in mind. Certainly, the average consumer, whose electrical knowledge will not usually go beyond the replacement of a fuse, should not be compelled to search through his distribution board to find the faulty circuit.

In some branches of the industry standardisation may bring about a harmful result, or at least it may impede development. In regard to fuses, however, it appears to us that the subject is essentially one that lends itself to standardisation with great advantages. The manufacturer would gain because he would know what was expected of him, and the number of sizes might be cut down to a minimum. On the other hand, the user would know that the fuse made by A. and rated at, say, 50 amperes, would give about the same result as the similarly rated fuse made by B.; whereas this is by no means the case at present.

REVIEWS.

(Copies of the undermentioned work can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 8*d*. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Hydro-electric Developments and Engineering. By FRANK KOESTER. (London: A. Constable & Co.) Pp. xxv.—442. 21s. net.

A rapid glance through the 440 quarto pages of this well-printed and beautifully illustrated book gives one the impression that it is a very valuable publication, but a deeper study tends to modify this opinion in some slight degree. Some parts are good and useful, but others are rather weak and a few even misleading. Thus, the author's way of treating the stability of dams is certainly open to grave objection. He assumes that the dam has a moment of stability equal to the product of its weight into the horizontal distance between its centre of gravity and the outside edge. This is wrong, as it would imply that the specific pressure at the outside edge might be infinite without crushing the material to powder. The correct way of calculating the stability moment is, as every civil engineer knows, to take as the horizontal distance a length appreciably less (something like two-thirds) of the distance of the centre of gravity to the outside edge. A dam designed in the way suggested by the author would certainly be less safe than he assumes.

On pages 15 and 16 some quite unnecessary instructions are given to the engineer who is called upon to design a power plant. He is told what staff he is to employ, down to the tracers, and how he should shift them from one office to the other, what size the drawings should be, how blue prints should be made and filed, and other things which each engineer will best settle for himself. There is also evidence in this part of the book of rather careless revision of figures. Thus, Galileo is cited as having made a certain pronouncement in the year 1830, whereas 1630 is, of course, meant; on page 14 a certain quantity of coal is given as 6 million tons, when obviously 600 millions are meant; and in some places the sense of the text is somewhat obscure. For instance, in the following passage, occuring on page 136, when dealing with different types of turbines: "During the operation much erosion was observed, and the turbines lost their efficiency, due to the increase of clearance between the runner and the guides. As these turbines are fed by glacier water, which in the summer contains much sand, the erosion still continued during the winter months, when the water is entirely free from same."

A very good feature of the book is the bibliography which is given at the end of every chapter, and which contains a large number of references to literature on the subject treated in the chapter. The general scheme of the book is convenient for its practical use. In the first part we find all those matters connected with the transformation of the waterpower into electric power; in the second the transmission of the currents, and in the third are given numerous examples of European and American works. In the first part we find chapters on Dams, Headraces, Penstocks, Power Plant, Turbines and their Governors, Generators and electrical equipment generally. The second part treats of the Line and Sub-stations, including transformers and converters; whilst in the third part eight different hydro-electric works are very fully described and illustrated by perspective views, plans and elevations.

In the chapter on Testing Turbines some information is given which makes one doubt the accuracy of American methods. The author distinguishes between what he calls the "European" method of testing the efficiency of turbines and the Holyoke tests. By "European" he evidently means an accurate method, for he gives from a German technical paper a table in which the efficiency guaranteed by the Holyoke staff is contrasted with that found by Prof. Pfarr for the same turbine when he tested it in Germany. In this table the turbine comes off rather badly, the efficiency found by Pfarr being about 10 per cent. lower; and in commenting on this the author says rather naively: "For these reasons, guarantees for such tests must not be accepted by the power-plant designer; he should accept only such guarantees as are made in the power plant itself." The sentence is a little obscure, for guarantees are not "made in the power plant," but the meaning seems to be that the tests as made at Holyoke do not give the true efficiency, and this interpretation of the author's meaning is corroborated by what follows, namely, "However, as the Holyoke tests are used in many respects as a standard in American practice, a brief description," &c.

What the author has to say on Pelton wheels is very interesting, and the illustration prepared from an instantaneous photograph on page 151, showing how all the velocity is taken out of the jet by the bucket and the water is quietly dropped, makes one understand how it is that such a wheel can work with high efficiency.

The best part of the book is that dealing with the line, and here the author's bias in favour of American methods is a

Digitized by Google

positive advantage, for in matters of line construction admirable pioneering work has been done by American engineers. The author deals with many essential points, both from a technical and a commercial point of view. Thus, the limiting transmission voltage at which dissipation of energy by what he calls the "corona effect" becomes serious is discussed with reference to Lyndon's Paper of a year ago, and a formula is given which is as follows:—

$$\text{Kilovolts} = 148(r+0{\cdot}07)\log_{10}\frac{D}{r}$$

D being distance between wires and r the radius of a wire in inches.

The statics of lines are fully discussed and useful information is given on many Continental and American methods of constructing towers for high-tension lines. As regards total cost of towers and insulators, an interesting problem presents itself. With a short span we have lighter and shorter towers, cheaper foundations, but more cross-arms and insulators, and also more labour in erection per mile of line than with a long span. The length of the span, then, influences certain costs in opposite ways, and there must be a particular length of span for which the total cost becomes a minimum. This problem is fully discussed by the author in the light of practical experience, and a close study of what he has to say on the subject will repay the labour bestowed on it. The line is a very important item in the total cost, and a vital item in the success of the whole undertaking, and for these reasons it is right that in a work as that under review the line should receive special attention. The author has duly appreciated this, and given us a most useful treatise on the subject of high-tension lines. The third part of the work, dealing with existing plants, will also be welcomed by engineers. The works selected are representative of good modern practice, and may, therefore, serve as examples for new designs, modified, of course, to suit special local conditions.

GISBERT KAPP.

ELECTRIC CABLES.*

ELECTROLYSIS.

BY F. FERNIE.

(*Continued from page 190*).

Summary.—The author first considers the general phenomena of electrolysis as observed in the neighbourhood of electrical networks. He then discusses in more detail the corrosion of lead-covered cables and armoured cables, and the effectiveness of earthing. Another cause of deterioration is electric osmose, which causes an accumulation of moisture at the negative conductor if there is any flow of current through the insulation. Finally, the causes of faults and measures for preventing them are considered. Faults may be classified into those of manufacture, those caused during laying, and those developed after the cables are laid. The last class is due to a number of causes, such as mechanical injuries, electrolysis and electric osmose, chemical action, overloading and decentralisation, high temperature, abnormal pressures and static discharges. Another cause of trouble is the accumulation of gas in manholes, causing explosions. The various ways in which gas may accumulate are considered and the remedies to be applied.

Armoured cables laid direct in the ground generally suffer more or less from electrolysis. Joints should be lead wiped and the armouring should be bonded on to the lead. However, with the most efficient bonding, a heavy fault current (to which such cables are peculiarly liable) will always cause some corrosion, owing to the resistance of the lead and armouring. Insulating joints undoubtedly limit the fault current, but will often increase the corrosion on the faulty section. Stoneware boxes have been used and boxes made of glass have been suggested. Wooden or ebonite bushes in the glands of an iron joint box should never be used; they always get wet and act as partial conductors. Bonding and earthing are not an absolute preventative; when a fault occurs part of the current may readily prefer to travel through 3 in. or 4 in. of soil on to some large pipe rather than by a circuitous path to earth along the lead. Also, simultaneous faults on a positive and negative cable may easily cause a heavy earth current between the two cables, the current taking a short cut via some pipe rather than the path provided for it. Steel armouring apparently often protects the lead from corrosion. It is sometimes found in practice that the armouring is pitted and eaten away along its whole length, but the only place where the lead is at all attacked is where the armouring has absolutely disappeared. In all cases *partial* measures are the least effective. Thus, earthenware or stoneware ducts are the very worst kind in relation to electrolysis. They act as partial insulators, rapidly absorbing moisture and becoming in effect electrolytes when only a slight difference of potential is applied. Those with metal joints are worst of all, as the joints act as partial earth plates. Cement joints, unless allowed to remain uncovered to set for at least 48 hours cannot be made watertight, and they also behave as electrolytes, and electrolytic corrosion may occur at every such joint. However high the resistance of a shunt to a circuit may be, some proportion of the current will flow through it, so that however well bonded and earthed a network is, if there are alternative paths for the current, they will be used, and, if these paths are electrolytic, corrosion will occur at the anode.

The problems most likely to arise are those connected with old networks, which probably incorporate a variety of methods of cable laying. The proper course to pursue and the best method of "nursing" such networks must vary in every case. An example of very extensive electrolysis occurring in practice may be quoted. A lead covered and braided cable, forming the positive main of a 460 volt three-wire system, was laid "solid" in an earthenware trough, in very wet heavy soil. It was surrounded by refined bitumen and supported on wooden saddles, which had been boiled in pitch and oil. After about two years' service, it was found that a length (about 50 yards) between two service joints (where the lead was discontinuous) was asunder. The leakage current was measured from both ends and the total was 0·25 ampere. On digging out this length, the cable was found to be almost completely destroyed. In some places, for continuous lengths of 3 ft. and more, not a vestige of metallic copper or lead was to be seen. These metals were replaced by a pale green salt (or salts) of copper (partly oxy-cloride), and a white salt of lead. A section showed these salts occupying exactly the relative positions and bulk of the metals in the sound cable, while the paper insulation was sodden, and in many places white in colour. The bitumen was generally good, but in patches it was brown in colour and friable. No action appeared to have occurred at the saddles. The troughing was cracked along its whole length, and was sodden with water. The cable had been well laid and was quite central in the trough, and not touching it anywhere.

This example shows that bitumen and stoneware are not necessarily insulators. The continuous and uneven crack in the troughing was similar to those caused in concrete by electrolysis. It is probable that if this cable had had its lead *efficiently* earthed, most of this damage might have been avoided, but as the fault was one that probably broke down very slowly, it would have been on some time before being located, and hence have involved the risk of damaging the lead at some distant point. Actually the lead on either side of the insulating joints was quite sound. Had the cable been laid in an insulating duct with isolated lead, the fault would have been noticed during a periodical inspection of the manholes, as soon as the lead became "alive," long before all this corrosion could have taken place.

A negative fault on a three-wire system nearly always damages the nearest gas or water pipe, the pipe being the anode of the circuit. Nearly all the fall of potential occurs within 5 or 6 ft. of the fault, since the fall of potential at any point near an ordinary fault in soil, plotted against distance follows a logarithmic law.

To give some idea of the conductivity of the soil in towns, it may be mentioned that between two stations in Glasgow

1,580 yards apart the earth resistance was found to be about 0·05 ohm.*

In mines there is great difficulty in obtaining a satisfactory earth, and it is partly for this reason that leadless cables are largely used. Trolley rails are not electrically continuous and the specific resistance of sandstone and shale is of the order 500,000 ohms per cubic centimetre, whilst coal may be as much as 50 thousand million ohms per cubic centimetre. If continuous currents are used, the safest method, *as far as electrolysis is concerned*, would appear to be to use concentric cables, the outer conductor being bonded on to the lead and armouring at the generator. The lead and armouring must be continuous throughout. No serious difference of potential can exist between the lead and the outer, and any fault affecting the inner must cause a short-circuit, which will blow the enclosed fuses. The armouring and lead can, of course, be "earthed" as well as possible to comply with the rules. It should and can be made impossible for the inner conductor to become earthed at any part of the installation without melting a fuse. Whatever type of cable is used, the armouring is chiefly relied on for an "earth" in mines.

Electric Osmose.

If an electric current be passed through a solution, containing two electrodes separated by a porous partition, there will in general be an increase in the volume of the liquid in the cathode compartment, and a decrease in the anode compartment, the liquid appearing to travel with the current. This phenomenon is called electric endosmose, with reference to the cathode.

Thus whenever a continuous electric current flows through a solution contained in a porous body, as soil, brickwork, earthenware, &c., or which is spread over an insulating surface, as a film of moisture on rubber or glass, then, in general, there will be an accumulation of moisture at the negative pole, and the neighbourhood of the positive pole will tend to become dry.

Prof. Haldane Gee† has shown how water is conveyed through blocks of concrete and plaster of Paris, and accumulates at the cathodes; some of the blocks were broken in half, after the passage of a current, and the halves next the cathode were found to have a lower resistance than those next the anode. Electrical endosmose is said to cause the destruction of overhead line insulators on traction systems, since "water is drawn between the iron bolt and the insulating material and is forced through from the positive metal of the bolt to the negative metal of the hanger."‡ On any earthed system of continuous-current mains, electric osmotic effects are sure to be noticed.

The first recorded instance was on the St. Pancras mains, which were bare copper strip strained in culverts. Here metallic sodium and potassium were formed at leaky insulators, and a number of bad explosions occurred. The same effect is common with all three-wire culvert systems, and often with "negative" switches, fuse boxes, &c., mounted on damp walls. The insulator must first become leaky, and this may be caused by a film of condensed moisture and dirt on it, but often part of the insulator is short-circuited by spiders, spider's webs, or flies getting under the petticoat. If it be a "negative" insulator the leakage current will be maintained by electric endosmose, which will keep the surface wet. The salts or metals formed are the result of the electrolysis of the water in the soil. If it be a "positive" insulator the leakage current will automatically cease, since there is no reservoir of water at the "positive" pole (the conductor) to keep the leakage surface wet. The "positive" conductors in a bare copper strip system always have a better insulation than the "negative," although a very high value can be maintained on the negative conductors too, if they are systematically tested, and all faults removed. Glazed stoneware insulators, supporting a negative conductor, sometimes become impregnated with salts, right through their substance, if the leakage has been going on for some time, and they have then to be renewed.

If the bare end of a wire connected to the negative side of a three-wire system be stuck into apparently dry ground, moisture collects around it almost immediately. The great trouble with 3-wire systems is to preserve the insulation of, negative conductors as, at exposed surfaces of porcelain, &c. there always tends to be set up leakage over the surface; and with lead covered wiring for instance, this is probably one of the main causes of failure.

As stated previously, there cannot be any electric osmotic effect on lead-covered cables, so long as the lead sheath is intact, but the question is one of great interest in connection with leadless cables. Before any such effect can be exerted there must be a leakage current through the insulation. Now, with high-class rubber insulation, the real leakage current *through* the insulation is practically nil, most of the observed current when testing, itself almost infinitesimal, being regarded as an absorption current, which gradually dies away.

Thus, before any electric osmotic effect can take place, the insulation resistance of the cable must fall; this may perhaps be caused by the absorption of water, which does take place with rubber and vulcanised rubber to some extent. If it be supposed that what may be called the "normal absorption" of water by the rubber does not much affect the insulation resistance, the deleterious action of condensed water could perhaps be explained if the water "normally" absorbed held some substance in solution, because this solution in contact with pure water would exert an osmotic pressure and tend to dilute itself by sucking in pure water, and thus an abnormal quantity of water might be absorbed.

Rubber is a colloid substance, and colloids "freely form addition products with such bodies as alcohol and water. . . . The process of absorption of water is often accompanied by considerable increase of volume. . . . Many solid colloids and solid solutions of colloids and water can be used as solvents for mineral salts and acids . . . the ionic mobility and the diffusivity are then very little less than in liquid aqueous solutions of equivalent strength."*

Rubber does swell up to some extent when soaked in caustic alkali for a few weeks, and it seems probable that it does behave to a very limited extent like the colloids referred to above, such as gelatine. This behaviour would explain the fall in insulation resistance, and, in the case of a "negative" cable, electric endosmose would, by forcing more water into the rubber, maintain the leakage current, and perhaps cause the formation of the big blisters containing alkaline liquid sometimes observed.

"Positive" faults on rubber cables drawn into underground ducts are less numerous than "negative," and their presence on ordinary straight lengths of cable may perhaps be accounted for by the fact that the liquid conveyed by electric osmose is not always forced in the direction of the current, but in some cases its direction is determined by the nature of the solution, whether acid or alkaline. Thus it has been found† that proteid dissolved in water reverses the direction of its motion, according as the liquid is made acid or alkaline; an acid reaction caused the particles to move with the electric current, which corresponds to the liquid moving against the current; with the liquid alkaline, the particles moved against the current, and hence the liquid would move with the current. Now a positive leakage current will produce, or tend to produce, an acid solution at the cable, and it is possible that this may reverse the direction of the electric osmotic flow of liquid, or at any rate largely neutralise it. So that instead of a "positive" cable tending to dry itself, as it will when the solution is alkaline (for example, the case of a thoroughly saturated "negative" cable changed to "positive") it may actually tend to suck in water.

THE EFFECT OF FREE TRADE OR PROTECTION UPON THE ELECTRICAL INDUSTRY.

On Monday evening last an interesting meeting, promoted by the National Electrical Manufacturers' Association, took place at Caxton Hall, Westminster, when a very interesting discussion upon the above subject ensued.

The Chairman (Mr. H. W. BUTLER), before calling upon Mr. Kingsbury and Mr. Hirst to open the discussion, stated that the reason why the National Electrical Manufacturers' Association had decided to promote the meeting was because the Association existed for the purpose of dealing with questions of general commercial interest to the trade, and was a platform where all members of the industry could discuss the various questions of policy which were a benefit to the trade as a whole. The Association as an Association was not able to take sides, and therefore no resolution would be put, and, further, it could not be responsible for any opinions expressed. He understood that the remarks of Mr. Kingsbury and Mr. Hirst had been prepared quite independently, and therefore could in no way be taken as answering one another.

THE CASE FOR FREE TRADE.

Mr. J. E. KINGSBURY, in opening the discussion on behalf of Free Trade, said that one of the effects of Free Trade was that the electrical industry of Great Britain had a higher efficiency than any in the world. In no protected country could the engineer extend his horizon beyond the frontier, or devise the use of the most suitable instrumentalities, regardless of their birth-place. In no protected country could he exercise his choice, except at a cost which was in addition to the value. In the sale of their material our engineers and contractors had been unhampered, and the nation had added nothing to the price. For some years past efforts had been made to misrepresent the operation of Free Trade by the development of an idea that the free tradesman required the engineer to limit his range of vision and the purchaser to fetter his freedom. The speaker asked which was the truer patriotism, to extend the benefits of the industry and add to the nation's profits, or to retard the development of industry and add to the nation's loss.

With regard to the electrical industry in particular our Free Trade policy had permitted us to apply at once any advance made elsewhere, and to give the industry a start on the most practical lines. As soon as the demand became large enough we abandoned imports and manufactured for ourselves. Thus we were able to make a start at once in any application, not originated by ourselves, and were able to adopt the most suitable instrumentalities to obtain the benefits of successful improvements at a small cost. On the other hand, Protection would have delayed us for years, and have enormously increased the cost. Protected countries were behindhand in the development of enterprise originated in other countries, while we were able to develop and adopt them without delay.

As regards our progress it had been pointed out that we were exceptionally backward as compared with protectionist countries. This was not the case, as in the United States, which was a particularly electrified nation, the electrical products in 1904 were 6s. 10d. per head of the population, while ours in 1907 were 6s. 2d., those being the years most nearly available for comparison. Our progress was in reality substantial, and lack of progress in any department could be readily accounted for by our errors. Free Trade had helped us, while with Protection our case would have been deplorable. Now that the industry was established these arguments were just as forcible.

As regards the protectionist argument that Protection made the foreign manufacturer sure of his own market, that he was thereby able to organise, with confidence, a supply for that market, and could arrange for the surplus to be exported, the difference between individual firms and the industry as a whole was not recognised. An individual foreign manufacturer was, in spite of Protection, open to the competition of other manufacturers in his own country. Protection, it was true, reduced the area of competition, but it did not reduce the actual competition. With regard to unemployment, nothing could be said as to the beneficial effects of Protection in this respect. There had been more extensive reductions of labour in the United States and in Germany, within recent years, than in this country.

One argument, the speaker thought, much in favour of Protection was its educative influence; but he thought that to start a factory for the purpose of serving as a school was an expensive form of education, and when maintained by protective tariff the amounts paid in advance would most likely be very serious.

The large amount of attention given to the profits of manufacture and the small amount of attention given to the purpose of manufacture could not be readily explained. A small agricultural community that placed a restriction on the importation of the best and cheapest spade was taking a measure that must react upon its own development. It would pay the community better to develop its resources by imported spades and pay for the education of artificers from its surplus crops, rather than to set those artificers to work to produce imperfect or unnecessarily expensive spades which would retard the progress of its manufacture. The value of the article in use should be the prominent consideration. Its use should be encouraged, and yet the principle of Protection was to discourage its use by delay or excessive cost. He had only called that spade a spade metaphorically. It might be called an electrical implement. Such an improvement which might now be imported from abroad in a finished state could not be placed at once upon the market if manufactured at home. For a year or two, say, the buyers of the improved apparatus were going to be asked to pay a royalty on what our heads had not devised or our hands fashioned. The proposal was that the nation should fine such purchasers for buying foreign wares, but the purpose of the fine was that we should get the benefit by restriction as much as possible to our own sources of supply. The effect of such restriction must be that the nation would lose in efficiency, the advantages of the possible economy could not be so widespread, and the demand would not assume proportions to justify economical manufacture at so early a period. Thus the home manufacture was likely to be delayed rather than accelerated by protective measures.

With regard to the question of dumping, a term which was identified only with national commerce, nothing could be said against the principle of leaving to the buyer the exercise of his individual will, but he thought it would be unbecoming to a great commercial nation with a world-wide trade for any section of its traders to endeavour to limit the freedom of the individual by the correction of a public sentiment based on national prejudice. If such principles had governed British commerce in the past, Great Britain would not be a great commercial nation, and if they were allowed to operate in the future Great Britain would cease to be a great commercial nation. In discussing such a subject at a time when there was not enough work to go round it was well to remember that what they were talking about was not the effect of Protection applied to electrical work alone, but rather what was going to be the position of the electrical industry if Great Britain gave up Free Trade and adopted Protection generally. If we were asked to adopt Protection so as to limit the freedom of action of those to whom we were selling, and other industries were being asked to do the same, it should be recognised that by their adhesion to those principles fetters were being prepared for the trade and the nation as well. It was all very well to adopt Protection. If they believed it was for the general welfare, they could do nothing less, but had all precautions been taken to assure themselves that it was for the general welfare? Where would the profit be if they procured their home market, and thereby reduced it to insignificant proportions?

In regard to the position of the home market in 1907 we imported roughly 20 per cent. for our consumption, a figure which might be divided by two to indicate the imports which were new or advantageous and those which competed with our standard manufactures. The novelties were wanted to maintain our efficiency and promote the use of accompanying manufactures of our own. Our grievance then was that 10 per cent. of our electrical consumption was imported and could have been made by ourselves. It amounted to a little over three-quarters of a million pounds. Did the case seem quite a strong one to put before the electorate? Was there not danger that some of them at least might remind us that the retention of our home market might possibly result in the ruin of our export market?

Our exports must grow, but we had keen and alert competitors. Every advantage at our disposal must be used. Free Trade was the greatest advantage of all. To our electrical exports we must look for developments, and we were asked to discard the weapon which we knew gave us our advantage in cheap production and promoted that over-sea trade which facilitated the exchange of our manufactures for others' products. And in place of the weapon which had proved its utility we were invited to adopt this protective armour of the middle ages whose deadly weight would crush us with more celerity and greater certainty than any other nation. The dependence of the electrical industry upon the general trade and commerce of the nation could not be questioned, and it was to be regretted that more attention was not given to such points and less attention bestowed on minor questions which, whilst making appeals to individual interest or sympathy, had much less effect on the real settlement.

Amongst the many other arguments for Protection it was often urged by moderate men who did not recommend Protection as a

Digitized by Google

good in itself that a tariff might be useful as a basis of negotiation and to permit retaliation. Could we say that any of our active competitors were so poorly equipped electrically that the operation of a retaliatory tariff was likely to lead to a reduction in their duties of any item which would facilitate our exports to them? They would agree the answer was No! In that event Protection as a retaliatory measure was useless to the electrical industry as it was equally useless in other respects.

It must be recognised that a difficulty existed in reaching a conclusion within the industry itself. A conclusion was more easily reached if the interests of the nation were considered. There could be no question then what was the interest of the industry. On foreign trade questions we adopted for ourselves a policy which we thought best. Other nations did the same, and were in no way influenced by our arguments. In such a progressive industry as ours, in which all cultured nations took an active interest, it was not reasonable to suppose that anyone could produce the best of everything. We had much that others could take with advantage to themselves. They shut their doors. Should we also shut ours? In the case of anything which benefited us it would be a mistake, and our Free Trade policy prevented our making such a mistake.

We must sympathise with the trader who found his sales affected or the profits reduced by imports from a country from which his own products were rigidly excluded, but if we legislated for hard cases we should start on the road to ruin. The operation of Free Trade was eminently fair. It might deal out hardship with one hand, but it promoted prosperity with the other. The trade returns of Great Britain, the condition of the population of Great Britain (in spite of all deputations and detractions) clearly demonstrated the wisdom of our fiscal policy. Whether it were regarded from that larger standpoint or from the more definite interests, the speaker thought it would be seen that the electrical industry only required to use its right arm and to make the most of its opportunities under the policy of freedom of trade.

Those who were not quite so satisfied as the speaker that Free Trade was essential to the progress of our industry could at least have no doubt that the effect on the electrical industry of the continual decrying of our powers which accompanied the agitation for Protection was extremely detrimental. If they had so little confidence of their powers in open competition there could be no surprise that others had even less. The best and strongest firm could not afford to lose goodwill. Now Great Britain's loss in goodwill in the last few years had been serious, entirely from the deprecatory arguments of the protective agitation. It would have been more serious but for the fact that our customers, our friends and our competitors had not taken us quite so seriously as we had taken ourselves. Unless they were satisfied that Protection was a real necessity, unless even they believed that the electorate could be convinced of that necessity, it was a mistake to continue the agitation for Protection.

The Case for Protection.

Mr. H. Hirst, in opening the discussion on behalf of Protection, said it appeared to him to be a very peculiar thing that although we grumbled at our present position as manufacturers individually around our firesides and on political platforms, electrical manufacturers as a body had been reluctant to express their views. Yet if our own and other industries were collectively to make known their opinions, and if the demands of the majority were heard, what a tremendous help it would be to statesmen of both political parties in their endeavour to do the greatest good for the greatest number. On the other hand, the most direful and misleading results could follow indecision and halting counsels on the part of industries like our own. When one industry shouted loudly for a continuance of Free Trade, and other industries, which needed Protection, remained silent, the result was bound to be harmful to the country. It might safely be stated that the indecisive results of the last election on the subject of Tariff Reform were largely due to the loud and insistent voice with which the cotton industry clamoured for Free Trade. Yet other industries of this country had a perfectly good and fair reply to give to the cotton spinners, and as that subject had now become one of general interest to the country he took this opportunity of suggesting a reply to what we had been told from Lancashire and Yorkshire. Mr. Hirst then briefly showed that the cotton industry was already naturally protected by the British climate, and that the cotton spinners' argument for Free Trade was really favourable to Protection.

Before proceeding with the discussion of the actual subject of the evening, the speaker showed that we were discussing "Protection and the Electrical Industry," not the electrical "trade." Speakers on this subject were not always careful to distinguish between trade and industry. Too many people in this country had got into the way of coupling "trade" and "industry" as if they were convertible propositions. But they were nothing of the kind. As a matter of fact, good "trade" might very conceivably be the absolute enemy of "industry," and in that case it would necessarily prove detrimental to the aims and ideals of Tariff Reformers. If trade was to be profitable in proportion to its volume, it was essential that it should busy itself only with the import of such commodities as the land was incapable of growing or producing, and with the largest export of such commodities as the land could and did produce. Was not, therefore, the vital question, Under what conditions can we produce cheaply? If you could establish such conditions as would enable the country to produce cheaply you could turn 80 to 90 per cent. or more of the inhabitants of this empire into producers. If you looked after the producer the consumer was automatically looked after, because consumers would then practically be also producers. But if the legislator kept only in view the consumer and neglected to force his country to produce up to the limits of its physical capacity, if, in short, he neglected to protect the producer and allowed outside forces to limit the field within which he could profitably work, that legislator was limiting the benefits of legislation to the smallest number of citizens instead of extending them to the greatest number. The Free Trader argued frequently as if the country were divided into two numerically equal sections, the producer and the consumer. But in an industrial country like ours, if it was to maintain a high state of efficiency, each consumer should also be a producer, though the nature of the production might vary.

The speaker maintained that Great Britain compared with its competitors had drawn nearest to this ideal state of efficiency at the close of that period of Protection which culminated in 1846. She was the chief producer amongst civilised nations. For a time the repeal of the Corn Laws appeared to have had the effect which its champions alleged as their guiding motive, to wit, the expansion of our power of production by the reduction of its cost. But the student of history who examined the facts with an impartial mind could only conclude that the results we obtained were snatched in spite of Free Trade. They certainly received a check as soon as other nations had the opportunity of so organising their economic forces as to place themselves in a position to challenge our industrial supremacy. It seemed that three factors, which were rarely mentioned, but which must be quite familiar to such an assembly as this, worked together to ensure our brilliant success as a producing country in spite of Free Trade, and these causes were operative until about the early eighties. These were Continental revolutions, steam, and the opening up of new markets.

In 1889 or 1881 Great Britain was at the zenith of her industrial power. Scarcely any engineering enterprise of any sort was set on foot in any country unless there were English brains, industry and capital at the back of it. How was it that in the short span of one generation our supremacy as a distributing nation was seriously challenged? How came it that in so many industries where we were leading we had either been caught up or overtaken, and that instead of being supreme we now occupied a secondary position? In discussing this point the speaker confined himself to the argument that under Tariff Reform or Protection we should be able to produce in very much larger quantities and by doing so we should be able to produce much more cheaply.

These two vital effects of Protection seemed to him all important. Engineers knew that in arriving at the cost price the quantity produced was a much more important factor in keeping the price of production lower than any advantage which a Free Trade country might have by somewhat cheaper raw material or cheaper labour. It stood to reason that a manufacturer who had a market of 60 millions of inhabitants secured to him, who had the advantage of preferential treaties with other countries and who could whenever he chose use for any surplus the markets of the Free Trade country, had invaluable points for producing cheaper than a manufacturer of a Free Trade country. In a secure market the outlay of works could generally, from the beginning, be a most efficient one. There could be standardisation or confinement to specialities, and, except in a period of depression, the manufacturer in a Protected country was sure of a continuity of orders. All these factors, again, tended to cheapen production, to the making of quick and big profits which attracted capital, and these profits seemed to be fairly divided between the state, the manufacturer, the workpeople and the investing public.

On the other hand, a man who started electrical works in England to-day realised that, to a great extent, he was entering on a gamble. It was very easy for him to build his works too large from a dividend point of view, or again he might make them too small for the work which might come to him, but it would be a very clever man who could exactly apportion his outlay to the work he could obtain. In this country the science of industrial economics was to a great extent

Digitized by Google

in an anarchical condition. We had no school of thought. Free Trade had produced a condition of intellectual drought. We were too apt to take for our pattern all that was done in other countries whether suitable for our conditions or not. Every manufacturer, small or large, was expected not only to copy the work of every manufacturer in every other country, but even if he set himself out to attempt this hopeless task it would not help him much unless he could show the man who had the order to give that he had in his works or elsewhere the exact machines which his customer might imagine were indispensable for the fulfilment of the order. The speaker could hardly suppose that the most dogmatic Free Trader would deny that our power to produce as cheaply as Germany under such conditions was possible.

We must, therefore, realise this fundamental and principal fact—that by producing regularly and in large quantities we could produce cheaper, and we were better able to supply our own colonial and foreign markets. If it were not so, the so-called advantages of our geographical position, most favoured nation clause, the best transport organisation for shipment to and from abroad, would have enabled us to have still kept the lead, but all these advantages failed us one by one as soon as our industrial position was being challenged by our competitors, simply and solely because we could not under our present conditions produce as cheaply. Every other reason put forward seemed mistaking cause and effect.

The principal reasons hurled at us for our decline were the absence of water power in this country, the backwardness of technical education, the lack of inventions, the apathy of British capital, labour troubles, dearer commodities. Mr. Hirst dealt with these points in order, and pointed out that the presence of water power was counteracted by the great capital expenditure necessary to erect hydro-electric stations. In early days our technical education was good enough for our purpose, but as long as our education was confined to learning what others were doing for the purpose of making the same things and selling them below their selling price (not necessarily below their producing price), and as long as we neglected the means which would enable us to produce cheaper to get below the cost of production of our competitors our technical education had no incentive to improve, and any amount of technical colleges would not improve our education when the incentive was missing. Under such conditions technical education was bound to advance at a rate which was never known before for the good reason that there would be a better market than ever for intelligence trained to cope with the technics of what will then be a profitable industry. But as things were to-day why should the foreman of our works, for example, send his boy to Birmingham University? He could afford to do it, but why should he when he saw that a draughtsman, a scientifically-trained engineer, got less than the wage of a shop foreman. The latest development in electric railways had reached us partly from Germany, partly from America. Well, it was a fact that in these countries several manufacturers combined some five or six years ago to experiment in electric railway traction. They formed an experimental company with a capital of £100,000. That was a bold, but doubtless a sound enterprise. Why was no such enterprise forthcoming in this country? The simple reason was that under similar conditions an English syndicate would have had no guarantee that any railway company in this country would have given them an order. There were electrical companies which had been most successful in Germany and America and which had established large works in this country. These companies had practically unlimited capital, they had at their disposal the best brains and experience available for this industry. From time to time such companies had sent us some of their best men who had done as good work in this land as they ever did in their own land, but what had been the result? It was no secret that without exception the financial results of these enterprises had been anything but satisfactory to the parent companies abroad. Now, if lack of technical education was the cause of our decline, why was it that these branch factories, equipped as they had been with the best technical and commercial men which our competitors could produce—why could they not make adequate profits? He thought it was fair argument that no amount of mere technical education would improve our present condition.

Some people were fond of casting in our teeth that we had not been fruitful in new inventions. It was perfectly plain that the manufacturer who worked in a protected country under such conditions as he had described had much more chance of meeting with his due financial reward than any manufacturer who had to get along under present conditions in Free Trade England. A great deal had been said of late about the influence of capital being always held ready to further industry abroad, while the apathy of the British capitalist was severely blamed for the backwardness of industry in this land. His experience was that you could always get capital if you could show good dividends. But we could not in this country show attractive dividends, and for this reason we were deprived not only of the immediate but also of the potential help of capital. We were told that if we had Tariff Reform we should have more trouble with labour. He could not agree with that view. It was a favourite argument with Free Traders that unprotected countries' commodities were dearer, but electrical engineers and manufacturers knew that the prime factor in determining cost prices was the quantity that could be produced. If we only had a duty of 10 per cent. foreign competing firms would well understand that that figure could be varied, and in that case they would be placed in the same position of insecurity in our market in which we were to-day. Under such conditions they would probably in organising their works be more careful to avoid over-production. They would not organise for working our market as they did now. Hence, instead of sending us an unknown quantity of foreign products and for ever depressing our prices, some of these competitors would doubtless start works here, which, of course, would be to the benefit of the working man and the State in general. The manufacturer, on the other hand, would not have any reason to grumble, because he would no longer be liable to be taken at an unfair advantage. The net result would be that we could turn out from our existing works continuously larger quantities, securing regular profits, giving regular employment and at the same time be able to reduce our cost of production. Assuming that last year we imported eight to ten million incandescent lamps, under a tariff of only 10 per cent. the bulk of those lamps would never have been imported, but would have been manufactured in the existing English workshops, many of which last year were running short time. The cost of production would have been reduced by at least the amount of the duty. Nobody would have been a penny the worse, but the factories would have made some profit and employment would have been larger and more regular to say nothing of the attendant advantage of a bigger wage fund for distributing among British operatives, which, of course, meant an increased power of expenditure in the home market for the benefit of every other industry.

In conclusion, he would put one question. Could our country be equally prosperous and equally secure if it ceased manufacturing altogether? If, in short, we were to buy all we wanted? It was possible that under such a system some people provided with capital and well found in experience might grow yet richer. But the effect of such conditions on, firstly, employment, second, on the national wealth, would be disastrous. Our rich stores of coal, iron, &c., were natural wealth, but of what value would they be to us if we made up our minds to let them lie in the ground? The nation which elected to follow out a Free Trade policy to its logical conclusion would be equally annihilating its powers of exchange. Grave as such a condition would be, the evil would not stop there. A nation which deliberately stopped manufacturing, that was using its material resources to the best effect, would be taking the shortest and directest route to national suicide. Those who came as he had into personal daily contact with many of the manufacturers of Germany, France and America, and discussed with them international commercial relations, knew full well that our competitors fully recognised it as a natural and necessary step that we should protect our industries. Now, as so great a portion of the world was still undeveloped and so many industries were in a state of germination and growth there was still time to put our houses in order, and march side by side with our German, French and American friends in the cause of civilisation. If we hesitated we encouraged them to increase their factories as well as their reliance upon the British market. So the day might come when any attempt to do what we could do now would be regarded as a direct disturbance of their national and vested interests which would be correspondingly resented. Thus it was his view that in the best interests of the country, as well as the electrical industry, manufacturers and workers should be protected now while it could be done with the good will of the nations.

DISCUSSION.

Mr. J. A. Raworth said that the subject under discussion was very restricted in its scope. He had undertaken to speak on the side of Free Trade as applied to the electrical industry, and he was not going to run Free Trade down, but back it up. He was born a Free Trader, bred a Free Trader, and he was afraid he was going to die of Free Trade. Mr. Hirst had taken out of his mouth one of the arguments which he was going to put before them. He was brought up in Lancashire, and knew the cotton trade almost as well as he knew the electrical engineering trade, and he knew perfectly why they did not want what was called Protection. They wanted Free Trade, but he pointed out that no great nation ever got into a position which entirely over-clouded all other nations in the way of trade and commerce and manufacture without being protected in some manner or other. In the first instance they were protected by the sea, secondly by the fact that they had all the coal worth having, having a 30 ft. seam in Staffordshire; next that they had the best climate for spinning cotton, and that Lancashire had the best brains and the best trained operatives ever produced by any country in the world. They

Digitized by Google

were protected by their position. Mr. Kingsbury did not take any notice of that; he called it Free Trade, and so it was to a certain point. He, the speaker, went into this business in the year 1878, and they had about four years of Free Trade, and he was making money about as fast as he could put it by. Then a proposal was made, he thought by Mr. Chamberlain, to protect the municipalities from the electrical engineers, and this was done under a bill which was set forth as being specially brought forward to foster the electrical industry. During the next six years everything was perfectly stagnant. In those five or six years, if they had had the Free Trade Mr. Kingsbury talked about, they would have been in a position when they could have gone ahead and carried everything before them. He knew that a good deal of money had been subscribed and a good deal squandered. Nevertheless they had not a fair opportunity, and because they had not got Free Trade the Germans were able to handicap them and get into the premier position. They made tramways as well as electric lighting apparatus, and he thought that most of them knew that 90 per cent. of the tramway machinery in this country had come from America. Turning to the question of investment: Not a single penny was being invested at the present time in any tramway undertaking in England, simply because they were still labouring under that old Tramway Act of 1870, which was made for the purpose of dealing with the horse traffic. His view about the case was that if they had left them to Free Trade and had given them the opportunity of dealing with the Corporations or local authorities and making their own terms they would have been all right. But if trade was interfered with in that manner trouble was sure to result.

Mr. E. W. Cowan feared that the division was too deep rooted to be even modified by the night's discussion. They were all agreed that the industry was sick, and he supposed they were all agreed that it was folly to stand idle under such circumstances. What was the disease? The production of electrical apparatus required the combination of certain necessary factors—viz., labour, capital, enterprise, ability of the entrepreneur, &c. Was capital receiving to-day in the electrical industry a "living" wage? Was enterprise receiving a "living" wage? The answer to both those questions was in an emphatic negative. That was the disease the industry was suffering from at the present moment. They might diagnose it as being "destructive competition." The disease originated in the environment of free imports, and it would continue its destructive course in that environment. A tariff on electrical imports only would afford relief, but there was not the remotest chance of a tariff being imposed upon electrical imports alone. The essential difference between the free importer's conception of "duties" and the Protectionists was that the latter believed the gain to some industries to be an absolute gain and the former regarded it only as a differential gain—*i.e.*, the gain to some counting loss to other producers. Nearly all the differences between the two views depended upon the root difference. Could they agree upon some compromise which was consistent with each side maintaining its own conception of the resultant effects of duties? He suggested that they should unite in banishing from the industry the rigid application of the doctrine of *laissez-faire*. Freedom in internal trade and freedom in international trade were both good things. But it was possible to have too much of a good thing. Competition was an excellent thing, but the electrical industry was getting a little more than was good for its economy. Could they not each go their own way in the matter of tariffs and unite upon that other ground? They could never have united action without sacrifice of some of their own particular notions, and without union they could do little. Therefore he said never mind the State, but let them voluntarily co-operate to (1) eliminate destructive competition, and (2) attain higher economy by the regulation and organisation of production. They did not need the assistance of the State to eliminate destructive competition, but they did need the co-operation of electricity supply works engineers and their committees and Councils and of consulting engineers. The support and co-operation of the consumers was, in his mind, essential to success. It should be realised that they were not combining to secure monopolistic profits, but to put their house in order for the benefit of those who used electricity and electrical apparatus, as well as for their own benefit.

Mr. G. Harland Bowden said there were certain firms which were successful organisations inasmuch as they obtained a certain percentage of such work as might be going; but, nevertheless, the electrical industry in this country could not be said to be in a flourishing condition. Putting aside prejudice, the electrical industry in protected countries was in a good condition, employing a greater number of men, who, it had been proved, were earning higher wages than those employed in this country. Taking the iron and steel industry, which was so dependent on electrical machinery for its process, steel manufactured in Pittsburg was sold at 20 to 30 per cent. lower than that manufactured in this country simply to get hold of the market. That steel should have a tariff on it. As to the numerous manufacturing firms who were erecting works abroad, and who were bound to erect them for the purpose of maintaining their markets on the other side of the wall, by putting a tariff on the products of those works one would get the works back to this country and thus increase employment.

Mr. Bennett Fitch said that the necessity of Tariff Reform was the most important question of the day. The main argument used by Free Traders was: "See how we have prospered under Free Trade. Why should we make a change, considering we have done so well and increased our wealth more in proportion than any other country?" As one who had followed the question from the early sixties, he desired to point out that the cause of our national prosperity at that time, previously and for some years later, was entirely due to our development of engineering and mechanical knowledge, every other country in the world being outsiders of those important points in those days. Men in this country invented the railway system and carried it out for many years all over the world. This country possessed further advantages by the fact that coal and iron were developed far in advance of other countries, and, being near the sea, reduced the cost of carriage, and consequently cheaper material than in other countries. A very clear explanation of the advantages this country possessed was shown in Meyers' Encyclopedia, published in Germany in 1849, in which the predominant position of this country was set forth. This country had command of every market in the world in those days, with no competition in any shape or form. The fact that this country was then able to supply cotton and woollen goods to all the world at the cheapest rate was due to our machinery improvements in the forties. Inventions in those times enabled one young girl to carry out work done by two or three men, with the result that for several years there was a great deal of unemployment, which, however, soon cleared away when our cheap supply of cotton, woollen and other goods enabled this country to supply the world without practical competition.

Mr. E. Garcke asked the chairman whether it was not possible to adjourn the meeting, as it would be very beneficial to hear the replies of Mr. Kingsbury and Mr. Hirst. Full justice could not be done to the question if they attempted to close the discussion.

The Chairman (Mr. H. W. Butler) thought Mr. Garcke's suggestion an admirable one.

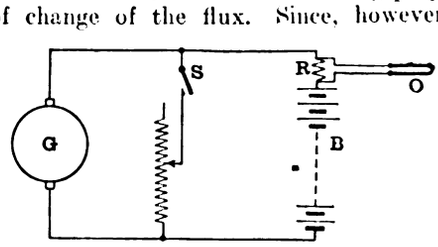
Upon a show of hands it was decided to adjourn the meeting until June 6th, at 8 o'clock, at Caxton Hall.

CORRESPONDENCE.

COMMUTATION PHENOMENA IN D.C. MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In Mr. Worrall's Paper recently read before the Birmingham Local Section of the Institution of Electrical Engineers, a method of examining commutation phenomena is described in which the pulsations of flux due to commutation are recorded by means of search coils suitably arranged on the pole shoes, the E.M.F.s. induced in the search coils being proportional to the rate of change of the flux. Since, however, the flux



pulsations occur in the axis of the main field, corresponding E.M.F.s will be induced between the main brushes by reason of the rotation of the armature in the pulsating flux.

We have been able, by means of the arrangement shown in the figure herewith, to obtain the flux pulsations due to commutation, and also the flux pulsations due to the armature teeth, without in any way disturbing the normal operation of the machine. The special feature of the method is that the E.M.F.s induced between the main brushes by the flux pulsations are directly proportional at any instant to the magnitude of the pulsating flux, and not to its rate of change.

A continuous-current generator is shown at G, and a battery, B, of E.M.F. equal to the generator terminal pressure is arranged in opposition. Some convenient load is connected across the terminals of the machine and battery. The load can be adjusted and also, by means of the switch S, entirely disconnected as required. A small non-inductive resistance, R, is placed in the battery circuit and forms a shunt for the oscillograph circuit O. The current due to any pulsating E.M.F. which may occur superposed on the main terminal voltage circulates through the battery and machine, and this is the only current through the resistance R since the steady pressure of the machine is balanced by the steady pressure of the battery. If the switch S is opened and the brushes placed in the neutral position, the pulsations so obtained are due to the armature teeth, and due also to the fact that the number of commutator segments is not indefinitely large. If the switch S is closed, and the machine loaded, the pulsations due to commutation are obtained superposed on the pulsations due to the teeth, &c.

If the test is carried out on a motor the compensating battery may be dispensed with, and the pulsating E.M.F.s separated by connecting the oscillograph circuit to the secon-

Digitized by Google

dary of a current transformer, inserted in the armature lead. In order to avoid undue saturation of the transformer core, a direct current should be sent from a low voltage battery through a second opposing primary winding, in series with which a coil of high self-induction is connected.

We have tried the method on several machines, and have observed the various effects. The optical arrangements of the oscillograph used were, however, not suitable for instantaneous photographs.—We are, &c.,

J. D. COALES.
T. F. WALL.

Birmingham, May 7.

PROF. FLEMING'S LECTURES IN TELEGRAPHY AND TELEPHONY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of May 6th you published the answers to a Paper set by Prof. Fleming on a recent course of lectures. These answers do not seem to be quite accurate.

In Question II. I make Z_0 nearer $571\angle 43°23'$ than $573\angle 43°23'$, and the receiving end P.D. $= 0{\cdot}144\angle 103°16'$ vector volts, the received current $= 0{\cdot}252\angle 146°38'$ vector milliampere, and consequently the answer to Question III., $I_2 = 0{\cdot}117\angle 65°44'$.

Also in Question IV. I make the "smooth" attenuation constant nearly 0·0339 instead of 0·032.

It would be interesting to know how the published results were arrived at.—I am, &c.,

E. P. ELWIN.

Anerley, S.E., May 17.

We have submitted the above letter to Mr. Dyke, from whom we have received the following reply:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Elwin's criticism of my solutions to Dr. Fleming's examination paper, the differences referred to in the answers to Questions II. and III. are very small and quite negligible in view of the use of the approximate formulæ for long lines. In Question IV. the "smooth" attenuation constant is certainly more nearly 0·034 than 0·032.

With regard to your correspondent's question as to how the results were obtained, I am afraid that a detailed solution of each question would occupy too much of your space, but I think that sufficient indication of the methods used has been given to enable those who attended Dr. Fleming's lectures to follow the work.—I am, &c.,

G. B. DYKE.

University College, London, May 24.

KEY SPRING CONDUIT.

The risk of damaging the insulation of wires in threading them through conduits, especially where sharp bends and elbows have to be negotiated, is so well known that any conduit system whereby this danger can be removed would be welcome. Such a system was shown, in its embryo stage, at the Manchester Electrical Exhibition

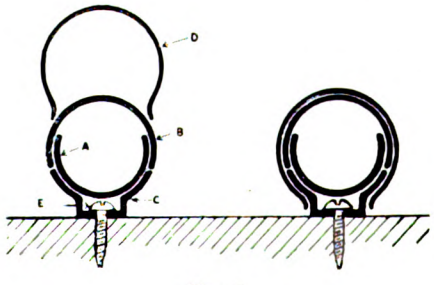


FIG. 1.

about a year and a half ago, and is now being placed on the market in an improved form by the Key Engineering Co., of 4, Queen Victoria-street, E.C.

The Key Spring Conduit, as it is called, is divided into two circular sections, each slightly greater than a semicircle. The bottom section of the troughing (A in Fig. 1) is supported upon the wall or ceiling on a simple bracket, C, screwed or nailed to the support, and is held temporarily in position by a spring clip (*see* Fig. 2). After the wires have been laid in place the cover B is sprung over the troughing, forming a complete circular conduit. Finally, the spring clip D is sprung over the complete conduit and edges of the bracket, thus rigidly holding the respective sections together, as shown on the right-hand side of Fig. 1.

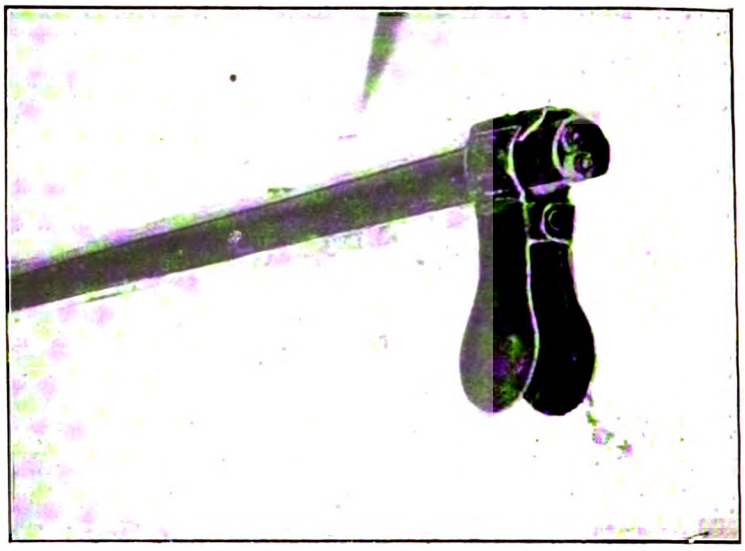

FIG. 2.—TEMPORARY CLIP FOR SUPPORTING THE TROUGHING AND WIRES.

It may possibly be thought that the arrangement shown in Fig. 1 is complicated. It must, therefore, be explained that in practice it is generally much simplified by the omission of the wall bracket C and the spring clip D. In this case small holes are punched in the inner section of the conduit A, and the latter is fixed directly on the

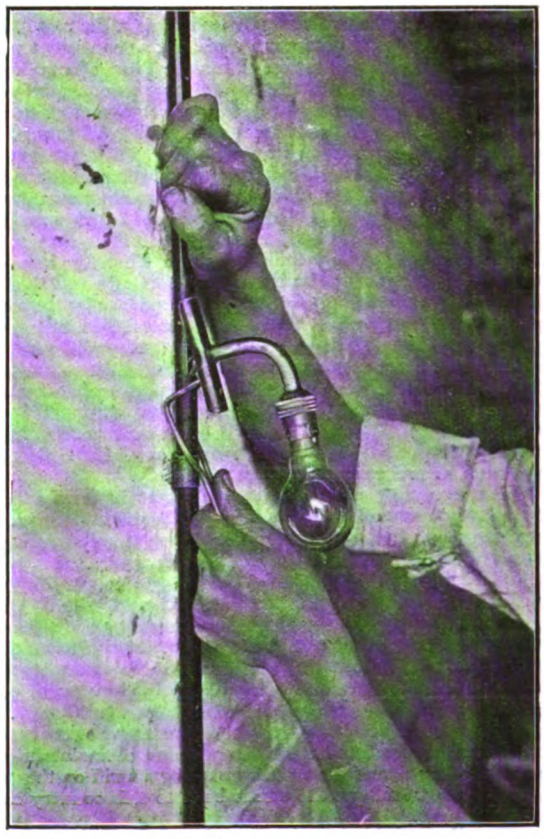

FIG. 3.—USE OF SPECIAL KEY FOR REMOVING COVER OF CONDUIT.

wall or ceiling by means of screws or nails. The conduit is shown in its simple form in Fig. 4.

Although the Key spring conduit is not water-tight, the overlap of the cover prevents the direct access of water. Also, it is claimed that condensation of moisture is prevented owing to the free evaporation provided. In this connection it may be mentioned that

Digitized by Google

owing to the conduit being constructed in two halves it is possible to enamel the interior very effectively, thus preventing the likelihood of the formation of rust to damage the wires.

Whilst it is practically impossible to pull the cover off without a tool, it is quite a simple matter to remove it by the special key provided for this purpose. The method of removal is clearly shown in Fig. 3. This illustration also indicates the simple process of attaching fittings by means of standard nipples and steel clips, which latter may be sprung on to the conduit at any point. If it is desired at

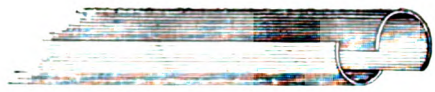

Fig. 4.—Key Spring Conduit.

any time to alter the position of the fitting, this can be very easily done by merely removing a short length of the cover and shifting the fitting and clip to the position required. It is evident that the fixing of pattrasses, ceiling roses, &c., is much simplified by the Key system. A ceiling rose fitting is shown in Fig. 5. It may be thought that a fitting which can be so easily sprung into position and so easily removed would be liable to slide out of position. This, however, is not so, and a weight of 112 lb. hanging from one of these spring fittings has not displaced the latter. A great advantage of the spring conduit system is that all wiring of fittings, &c., can be done on the bench before the wires are laid in the conduit.

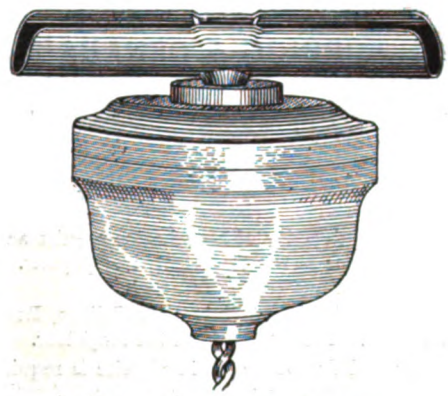

Fig. 5.—Ceiling Rose Fitting.

An effective system of bonding adjacent lengths of conduit has been adopted where electrical continuity is desired, copper rivets being expanded in newly-punched holes in the troughing. A simple screw punch is provided for cutting a clean hole in the exact position required; one of the special bonding pieces illustrated in Fig. 6, and in which the copper rivets are already fixed, is then riveted to the conduit, a special riveting tool being provided by the Key Engineering Co.

Bends and tees are constructed on the same principle as the conduit—that is to say, they are built up of two circular steel sections

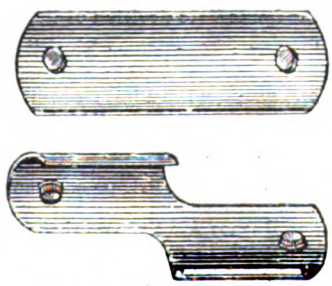

Fig. 6.—Bonding Pieces.

which are sprung together. It is also worth remembering that Key inspection fittings can be used with ordinary draw-in systems. A tee piece for such a purpose is illustrated in Fig. 7.

To show the rapidity with which the Key spring conduit may be installed, it may be mentioned that at the Manchester Exhibition, starting with bare walls, a complete installation, consisting of 20 ft. of conduit, a right-angle bend, a switch, a single-light fitting, a three-light fitting and a pendant fitting were installed by a wireman and assistant and all lights turned on in under two minutes (not including the wiring of the fittings, done previously).

There is no doubt that the possibility of having all wires accessible for examination at any time should bring the system into favour with consulting engineers, whilst the many other advantages possessed by it, such as the possibility of using smaller conduits (since

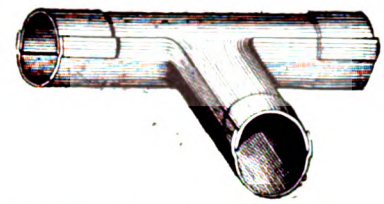

Fig. 7.—Tee for use with draw-in system.

the wires have not to be drawn in), the ease with which the position of fittings may be altered and the saving in labour, are likely to appeal to wiring contractors generally.

LEGAL INTELLIGENCE.

Société Indusdrielle des Telephones v. Nussbaum.

On Tuesday Mr. Justice Grantham and a special jury commenced the hearing of an action, brought to recover £782. 5s. 9d., balance of money alleged to have been received by defendant as agent for plaintiffs. The debt was practically admitted, and defendant paid into court £600, the amount disclosed by the accounts, but he counterclaimed in respect of breach of contract and loss of commission on business which he failed to secure owing to the conduct of plaintiffs. Under these circumstances defendant took the position of plaintiffs and sought to prove his counterclaim.

Mr. Lewis Thomas, K.C., for defendant, said plaintiffs had not carried out their work according to contract or to time, in consequence of which defendant had suffered damage by loss of orders. In one case the contract was that English pig lead should be used for covering cables, but it was found that Spanish lead was used. Plaintiffs, however, protested, while admitting the use of the Spanish lead, that they derived no advantage from it. They attributed the substitution to the difficulty in obtaining supplies of English lead. Some of the telephone wires had to go underground in conduits and others overhead. In regard to the former it was found that the cables had too large a diameter, and in regard to the latter some of them were too heavy and did not comply with London County Council's regulation which was that no aerial cable should exceed 1 lb. in weight per foot. There were also constant complaints of delay in delivery, and in consequence the National Telephone Co. declined to place a second order until the first was executed. Thus defendant lost much business and a large amount of commission which he would otherwise have received. For this he claimed, together with money spent by him for the company and expenses incurred owing to their failure to complete orders to time.

Mr. Nussbaum said he had been in business in England for 25 years. He had, since he first did business with plaintiffs, worked for them only, and had done business to the extent of about 1,000,000fr. a year. There was a written agreement in 1891 with plaintiffs' predecessors, and he went on upon the terms of the old agreement. He had London offices and a salary of £120 a year and commission. He had been in touch with the National Telephone Co. for years, and since 1904 he was in a position to place their orders where he liked. He introduced the National Telephone Co. to plaintiffs, and the result of the introduction was an arrangement by which plaintiff company should get the orders, they having stated that they would be able to deliver three miles of cable per week. Mr. Léauté, a gentleman connected with the company, said that they were getting new plant for indiarubber-covered cables. He placed a large amount of orders with them, but they did not execute them to time. If they had carried out their contracts to time his commission upon the orders would have amounted to £1,500 a year, but he did not get more than half that amount. He claimed for this lost commission. On no single occasion were the goods delivered by plaintiffs to time. The complaints were forwarded to plaintiffs. Mr. Nussbaum detailed a number of complaints which he had had occasion to make to plaintiffs in respect of the manner in which they had carried out orders forwarded to them. He had been requested by Mr. Léauté, of the French company, to retain his agency until the current contracts were finished. He consented, and stated that there would have to be an alteration in the terms of the arrangement after that. As late as March and April of last year the company had communicated with him as their agent. They wrote to him with reference to orders executed for telephone fittings.

In cross-examination by Mr. Montagu Lush, K.C., witness said that he could not do other business because he was still engaged with plaintiffs. He had, however, been in negotiation with several firms with a view to business, but they all told him first to finish his affairs with plaintiffs. He had been doing business with the Société before 1890. He first bought from them telephones as a merchant, which he sent out to Australia. From 1891 to October, 1908, he only did business with the

Digitized by Google

Société Générale and the Societé Industrielle. It was one of the terms of his engagement with the French company that he should remit all money received by him for the company within a week or two, and he continued to do so down to 1908. He had in his employ a clerk who falsified his accounts and forged an endorsement to a cheque, and that threw his accounts into some confusion. The difficulty which arose with regard to the French company's accounts was not due to that, but to the confusion into which the company's affairs had got. Plaintiffs ought to have found out that his clerk was a forger. He had kept the £600 as a guarantee Plaintiffs had broken the contracts several times and he could not get any satisfaction from them. so he thought he ought to have a guarantee that they would finish the contract then running. The £600 was paid into the bank, and he told them that he would pay it into court.

Mr. DUDLEY STUART, of the National Telephone Co., gave evidence as to the orders which had been given through defendant to plaintiffs and the manner in which they had been executed.

This closed defendant's case, when his Lordship invited counsel to consult him in his private room. The consultation lasted over an hour, and in the result Mr. Lush, on returning into court, thanked his lordship for the opportunity which he had afforded the parties of arriving at a satisfactory arrangement.

His LORDSHIP said he was glad the parties concerned had come to an amicable settlement under which a portion of the £600 paid into court would be paid out to defendant. Plaintiffs were naturally incensed, but they had acted in a straightforward manner, and defendant had unfortunately acted hastily. The letters which had passed convinced him that defendant was an honest man and that plaintiffs were acting honourably by him. He thought plaintiffs had acted fairly and honourably in the way they had treated defendant, and that the defendant was wise in accepting the settlement.

Aberdeen Station Hotel Co. (Ltd.) v. Aberdeen Corporation.

In the Bill Chamber, Edinburgh, last week, counsel applied on behalf of plaintiff company (in liquidation) to have the Corporation of Aberdeen interdicted from cutting off the supply of electrical energy to the hotel. The Corporation had threatened to stop supply because the company were in arrears with their payment of rates.

Counsel for complainers (Mr. CRURIE STEUART) said the Corporation were seeking to secure a preference over other creditors, although they were an unsecured creditor; and he submitted that the note should be passed for the trial of the case, and that interim interdict should be granted.

Mr. CHREE, for the Corporation, said the proposal was to interdict his clients from taking a statutory remedy for the recovery of the rate. Sec. 23 of the Aberdeen Corporation Act, 1907, gave them power to cut off supply to anyone in arrear. It was not a matter of controversy that the complainers were in arrear, because the usual half-yearly account rendered in January had not been paid. A liquidator was not in the same position as a trustee in bankruptcy, because nothing was vested in a liquidator, who merely managed for the company, which continued to occupy the premises in his person. They did not object to the note being passed, but they did object to interim interdict being granted, except on consignation of the amount due, which was £125.

Lord CULLEN said there was an obligation on the Corporation to supply electricity so long as the consumer was not in arrear. The moment the consumer got into arrear the obligation fell. His lordship refused the note

Liability for Colliery Explosions,

In the Outer House of the Court of Session (Edinburgh), last week, Lord Salvesen allowed proof in three actions brought against Archibald Russell (Ltd.) by the representatives of three miners killed by an explosion. Mrs. E. Tonner (or Tait) sued for £1,000 for herself and £1,250 for her children; Mrs. P. M'Millan (or Adams) claimed £1,000 for herself and £750 for her children; and Mrs. M. M'Vey (or Hunter) sued for £1,000 for herself and £250 for her child. The miners were killed in consequence of an explosion of gas which took place in the Virtuewell seam of Forniegair Colliery, near Hamilton, belonging to defenders. Pursuers' alleged that the explosion was caused by a spark from the trailing cable of an electric coal-cutting machine, which cable one of the men was engaged in lengthening at the time of the accident. Defenders, who denied negligence and pleaded contributory negligence, stated that they believed the explosion was due to deceased (one Francis Tait) lighting his pipe either with a match or by opening his lamp. Smoking and the use of a naked light in that section of the pit were strictly prohibited. They denied that sparking could take place as suggested, but stated that if it did the spark was due to the negligence of Adams or otherwise of Hunter in failing to switch off the current at the gate-end box before proceeding to lengthen the trailing cable.

Lord SALVESEN said he had come to the conclusion that this was a case in which he should exercise the discretionary power which he had of dispensing with issues and appointing the case to be tried before the Lord Ordinary without a jury. He was the more disposed to do so as he thought there was no class of case in which a jury was more liable to go astray than that which related to operations underground, of which they had generally no personal experience. The danger of miscarriage was increased (1) because of the highly technical evidence which would be given as to the proper system of working electric coal-cutting machinery, and (2) because of the legal controversy with regard to the application of the various special rules relating to the particular pit.

Eccles Corporation v. South Lancashire Tramways Co.

In the Court of Appeal yesterday (Thursday), before the Master of the Rolls and Lords Justices Farwell and Kennedy, plaintiffs' appeal was heard from a judgment of Mr. Justice Eve dismissing an action for a declararion that Salford Corporation were not entitled to authorize defendants to use plaintiffs' tramways, or any part thereof, and for an injunction to restrain defendants from running cars over a short section of plaintiffs' tramways within the borough of Eccles. The facts of the case were reported in THE ELECTRICIAN for 24 Dec., 1909 and 28 Jan., 1910.

At the conclusion of the arguments of counsel, their lordships allowed the appeal, holding that what Salford Corporation had done in granting the licence to defendant company to run over the sectinn of the line in question without the consent of the Board of Trade was *ultra vires*. The appeal was, therefore, allowed, and the relief claimed granted, with costs. Plaintiffs undertook not to enforce the injunction for a month.

Wheeler v. Marylebone (London) Borough Council.

Mr. Justice Grantham and a special jury yesterday (Thursday) commenced the hearing of this action, brought by plaintiff (a builder) for the recovery of damages for personal injuries alleged to have been sustained through the negligence of the Council's servants.

Mr. DRAKE, K.C., in opening the case, said, that plaintiff was re-building a house in Devonshire-place, and running through the vaults of the house was an electric cable. The housebreakers employed by Mr. Wheeler gave the Council notice to cut off the electric current, but one day in April, 1908, Mr. Wheeler saw what he thought to be an old lead pipe and went to cut it away with a chisel and hammer. After two or three blows on the pipe an explosion occurred, a sheet of flame lit up the place and plaintiff was violently thrown against the wall (some 4 ft. away) and was severely injured. Plaintiff's left hand was badly burned, the nail of his thumb was burned off and his clothes were damaged; he had received a severe shock and was under medical care for some time.

Evidence for the plaintiff was taken, and the hearing adjourned.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the position of borough electrical engineer at Salford. Salary £500 per annum, rising to £700. Applications to the town clerk, Mr. L. C. Evans, by June 13. See an advertisement.

The Council of the University of Manchester require an assistant lecturer and demonstrator in the department of physics. Applications to the Registrar by June 13.

The professorship of physics at University College, Reading, will shortly become vacant. Particulars from the Registrar.

A junior lecturer and demonstrator in physics is required at the University of Sheffield. Salary £150 per annum. Applications to the Registrar by June 1.

A test room assistant, well up in a.c. and d.c. work, is advertised for.

Mr. A. J. Abraham, resident engineer at Lanark County Council's electricity works at Cambuslang, has been appointed clerk of works of the Aberdare electricity supply scheme.

Mr. W. K. Thomson has been appointed manager of the electrical department of Messrs. Renton, Holdsworth & Co., Sheffield.

Acton.—The position of the electricity undertaking was again discussed at the last meeting of the Electricity committee, and, after a lengthy debate, it was resolved "That the position of the electricity undertaking demands the immediate decision of the Council."

Argentina.—The "Review of the River Plate" states that the plans of the National Tramway Co. for the conversion of La Plata horse tramways to electric traction have been approved.

New telegraph land lines, 556 km. (345 miles) in length, are to be constructed in Argentina.

The Compañia Electricidad de la Provincia de Buenos Aires have purchased for $1,000,000 (paper) the electric power plant which supplies current in Mar del Plata.

The Belgian Legation at Buenos Aires report that Cordoba Province and the Andes districts import 15 million francs value of electrical materials per annum. Germany supplies the demand in the ratio of 491 per 1,000, the U.S.A. 98 per 1,000 and the U.K. 312 per 1,000.

Australasia.—The placing of the telephone lines underground at Ballarat was recently commenced.

The Defence Department have applied to the Minister for Public Works for an order authorising the erection of cable from Melbourne to transmit current for electric lighting at the Maribyrnong cordite factory. The line will traverse Footscray and part of the shire of Braybrook.

Malvern (Victoria) Council have obtained the necessary authority from the Governor in Council to construct a tramway in Glenferrie-road, and notice of a resolution to take further steps was recently given by Coun. Thomson.

Digitized by Google

Emu Bay Council are considering the relative merits of gas and electric lighting for use in the town of Burnie (Tasmania). Mr. G. H. Lofts has prepared a preliminary report. The secretary of the Hobart Gas Co. has submitted an estimate intended to show that the cost (with renewals) of a 60 c.p. inverted incandescent gas light, with gas at 6s. 8d. per thousand, for 1,500 hours, would be £1. 16s. 6d., for upright mantle £2. 5s., for 50 c.p. metal filament electric lamp £2. 18s., and for 50 c.p. carbon filament lamp £6. 13s. 6d., current in both cases costing 6d. per unit.

On the other hand, Mr. Percy Rosling estimates that the cost of equivalent lighting would be as follows: Inverted gas burner £1. 16s.; upright burner £2. 5s., metal filament electric lamp £1. 15s. 3d.

With a view to expediting the proposed construction of an electric tramway from Melbourne to Williamstown, a poll has been taken at Williamstown to ascertain the probable demands which would be made for purposes other than traction in the event of a supply being provided for private consumers as well as for tramway purposes. Those in favour of the lighting proposition were: Property owners 632, out of 842 approached, occupiers 691, out of 898. Eleven factories will take electric power and 424 occupiers will take supplies for lighting.

Queensland Government has granted a further loan of £8,000 (making £33,000 in all) for the construction of Rockhampton Corporation's tramways. The Finance committee reported about a year ago that the cost would be increased 20 per cent. owing to the increased rate of customs duty on such material as had to be imported, to the substitution of heavier rails, &c.

Barking.—The electrical engineer (Mr. H. Howard) has prepared a report upon three alternative schemes for the extension of the generating station or the removal of the plant to a new site. Mr. Howard has been instructed to report upon laying an underground cable through Faircross Estate to Upney.

Belfast.—A report has been prepared by the general manager of the tramways (Mr. Andrew Nance) in which certain extensions of the tramway system are recommended.

Borough Polytechnic Institute (London).—A special course of six lectures and practical demonstrations on the "O.S." wiring system, using "Stannos" wire, will be given by Mr. Chas. Rawlings on Monday evenings from 7:30 to 10, commencing May 23. The course is only open to journeymen wiremen

Cardiff.—The Parliamentary committee have been instructed to report upon a proposal to extend the tramway service to Llandaff and Whitchurch.

Clitheroe.—The Board of Trade have deferred the revocation of the electric lighting order (1904) for a year, and intimate that it will be revoked at the end of this period unless evidence of the Council's intention to put the order into force be forthcoming.

East Budleigh (Devon).—The Parish Council have decided to call in an electrical engineer to report upon the lighting of the village.

Edinburgh.—The Electric Lighting committee will supply electrical energy for the new Slateford-road tramway at 1¼d. per unit for the first year.

The engineer (Mr. F. A. Newington) has been asked to report upon the proposal to extend the mains to the Barnton Park estate, where a number of householders have agreed to take current and to guarantee to use a certain amount of current for three years. It is also expected that residents in Blackhall and neighbouring districts will avail themselves of the opportunity of taking current.

Electricity in Flour Mills.—The flour mills of Mr. J. Rymer at Kilvington, near Thirsk, have been provided with an electric lighting and power installation. The generating plant was supplied by Siemens Bros. Dynamo Works and the installation work was carried out by Messrs. Reddin & Sons.

Electricity in Mines.—We have received from the "Colliery Guardian" a reprint of a Paper by Prof. W. M. Thornton on "Electricity in Mines." The pamphlet forms one of a series of Coal Trade Pamphlets issued by our contemporary at 1d. each, by post 1½d.

Electricity in Mining.—At the meeting of the Waihi (N.Z.) Gold Mining Co. last week the chairman (Mr. A. M. Mitchison) said that during the year the hydro-electric scheme for generating power at Hora Hora Rapids had again been the subject of negotiations, and the company had been successful in obtaining a concession for the use of the water. Having regard to the length of time required for the completion of hydro-electric works of that nature, a careful examination of all the aspects of the case was made and it was decided to again apply for the concession. In all the circumstances they felt confident that the Hora Hora electric power would allow further economise to be effected, and they hoped, moreover, that the development of one of the many sources of water power in New Zealand would be of service to the Dominion.

Fleetwood.—The demand for electrical energy for lighting and power is increasing so rapidly that extensions of the generating plant and mains will have to be considered.

Glasgow.—The Electricity committee propose to extend the electric supply cables to the Scottish Exhibition of National History, Art and Industry, where current will be supplied at 2d. per unit for lighting and 1d. for power. It is anticipated that the annual revenue will be £4,600.

Grays.—44 Nernst lamps are to be replaced by metal filament lamps of 100 c.p. and 200 c.p.

Hadleigh.—The Parish Council have asked Southend Council to extend the tramways into this district.

Hampstead (London).—On the recommendation of the Electricity committee the salaries of the following officers are to be increased:—Mr. George H. Cottam, chief electrical engineer, from £775 to £825 per annum; Mr. Egerton Sayer, chief assistant, from £365 to £390 per annum; and Mr. John Leadbeater, chief indoor assistant, from £325 to £360 per annum.

Havana.—The President of Cuba on Saturday last inaugurated the new telephone system of Havana, owned by the Cuban Telephone Co. (Ltd.)

Huddersfield.—The Corporation are negotiating with Linthwaite Urban Council for the purchase of the Linthwaite tramway lines, and an offer of £4,000 has been made for the track. Should the purchase be completed the track will be doubled.

India.—"Indian Engineering" states that the power house at the East Indian and Bengal Nagpur junction at Asansol is to be extended to supply current for lighting the East Indian Railway offices and staff quarters at Asansol.

The services of Mr. A. E. McCloskey, of the engineering department of the G.P.O., in England, have been loaned for two years to the Bombay, Baroda and Central India Railway Co., and he will act as assistant electrical engineer in the company's telegraph department at R.600 (£40) per month.

During the absence of Mr. R. E. Pigott on six months' leave, his duties as chief electrical engineer of the B.B. & C.I. Railway will be performed by Mr. H. B. Saxby, who will also continue to occupy his present position as electrical engineer of the Ragputana-Malwai State Railway.

The electrical equipment for the E.I. Railway coal yard at Howrah has been ordered from England.

Kettering.—The salary of the electrical engineer, Mr. W. A. Walker, has been increased by £50 per annum.

Lapland.—The Swedish Parliament has voted £1,204,000 for the erection of an electric power station near the Porjus Falls, in the Lule river, Lapland, to supply power to the railway between Kiruna and Riksgraensen (on the northern frontier). Electric power will also be used in the district of the falls for reducing iron ore into pig-iron.

Leicester.—The Rural Council will sanction the proposal of the Corporation to supply electricity in Oadby and other parts of the rural area.

Light Railways.—The report of the proceedings of the Board of Trade and of the Light Railway Commissioners up to Dec. 31 last has been issued.

On Dec. 31, 1908, nine light railway orders were before the Board of Trade awaiting confirmation; eight were confined in 1909, and one is still held over. During the past year 13 fresh orders were submitted to the Board by the Light Railways Commissioners for confirmation, and after hearing objections the Board confirmed eight of the orders, the remaining five being under consideration on Dec. 31, but three of these have since been confirmed. The 16 orders confirmed in 1909 authorised 68 miles of line, at an estimated cost of £300,399. Since the date of the last report the Treasury have conditionally agreed to make free grants (aggregating £26,913) in aid of three light railways.

The report of the Light Railway Commissioners states that a total of 599 applications for orders to authorise light railways (including 98 applications for amending orders) have been made since the commencement of the Light Railways Act, 1896. In respect of 379 applications (13 in 1909 and 366 in previous years) orders have been submitted to the Board of Trade for confirmation; four other applications, in respect of which orders are under settlement, have been approved, and 199 applications have been rejected or withdrawn. The decisions with respect to 8 applications have been deferred, and 9 of the 10 new applications made in November last remain to be considered. Upon examination of the lists of orders granted the Commissioners find a large number of light railways the need for which has been established at public inquiries held by them, and for which orders have been confirmed by the Board of Trade, but of which the construction has not (so far as the Commission is informed) been proceeded with, and as to a large proportion of which the powers have already lapsed. Whereas 46 light railways, with a length of 375 miles, in class A. (lines on lands acquired, mostly steam motive power), and 54 light railways with a length of 326 miles in class B. (lines on public roads, mostly worked by electric power) have been constructed, the powers given by the orders have not been carried into effect in the case of 61 schemes with a length of 765 miles in class A. and of 35 schemes with a length of 210 miles in class B. These powers have finally lapsed for 33 schemes (421 miles) in class A. and for 24 schemes (138 miles) in class B. The chief difficulty in proceeding with schemes already authorised has been in finance, while the failures enumerated above have had the effect of deterring other proposals. In relation to lines of class B., experience has shown that the absence of any provision under the Act of

Digitized by Google

1896, for "submitting to Parliament" proposals which are required to be so submitted in accordance with the Act, renders the procedure unavailing, and practically unavailable, in many cases. To what extent, and in what way, the policy of the Act should be revised must present a difficult problem; but the Commissioners draw attention to the marked success of the system adopted in Belgium, under which a total length of more than 2,000 miles of light railways, constructed with moneys raised on national credit, is already being worked without loss to the State, while a further length of some 2,000 miles has been projected.

Manchester.—At the Corporation meeting on Wednesday Ald. Holt moved, as an amendment to the motion for the adoption of the estimates of the Electricity committee, that the committee should add £5,000 to their contribution in aid of the city rates. The amendment was, however, rejected.

On the motion to adopt the estimates of the Tramways committee, Mr. Lofts moved an amendment that the estimate of £82,537 for renewals and depreciation be reduced by £25,000, and that amount paid to the city fund. He urged that there was already a large reserve fund of £471,865, which was ample to meet all contingencies, with the sum which would be added if his amendment were accepted. This amendment was also defeated.

Municipal Telephony.—The manager of the Hull municipal telephone department (Mr. T. Holme) has presented his annual report for the year ended March 31.

Gross receipts were £11,670, increase £1,078 compared with 1908-9, and after paying expenses there was a gross profit of £4,823, increase £380. The amount transferred to loan repayment was £1,994, against £1,786, making the total carried to loan repayment account £5,668, to temporary sinking fund £1,948 and to reserve fund £3,380, total £12,166 after deducting cost of diverting Post Office junction circuits. The Government royalty for the year was £1,188. Capital expended is £60,315, compared with £57,858, increase £2,456. During the year 1,620 yds. of underground conduits were laid, extending the system by 154 miles of metallic circuit. The total conduits now laid measure 37 miles, and the underground mileage equals 4,050 miles of metallic circuit.

In regard to overhead construction, the capital expended during the year had (the report continues) been incurred in joining up additional subscribers and extending the overhead routes by the erection of 27 poles. The total overhead mileage is now 581 miles of metallic circuit, and the number of poles erected is 1,370. The cost per station now stands at £20·58, compared with £21·42.

The chairman (Ald. J. BROWN) said this was the fifth annual report, and was the best of the five. They had made a profit since they began of £10,782. They had reduced the subscription of telephone users by about one-half, and yet were able to show a satisfactory financial result. That showed the great mistake that had been made on the part of the municipalities who had not installed their own telephone system. He thought it was a credit to the city that they had carried the system out so satisfactorily. They had not only done well for themselves, but they had done well for the Government. They had been told recently that the Government could not make either the telegraph or telephones pay, so they might take a leaf from Hull's book.

The report was adopted, the net profits being carried to revenue account

National Electrical Manufacturers' Association.—A meeting was recently held in Manchester to form a northern section of this association.

The meeting was well attended, and it was resolved that the section should be formed. Mr. B. Longbottom was elected hon. secretary and the following firms have since joined the association:—E. Brook (Ltd.), H. T. Boothroyd (Ltd.), Clarke, Chapman & Co., Evered & Co., Liverpool Electric Cable Co., Bertram Thomas and Wright & Wood. Several other firms have since sent in applications, and the result is that a strong section of the association is formed which will deal with local matters directly. In consequence of opinions expressed that the association should be more national in character a revision of the bye-laws has taken place.

Obituary.—The death is announced of Mr. Geo. Bremer, who was for over 20 years chief country representative of Mr. G. Braulik.

Rugby.—The chairman of the Electric Light committee (Mr. Dewar) made a statement at the last meeting of the Council as to the financial position of the electricity undertaking.

He said that the committee were satisfied with the progress of the undertaking, and had directed that £500 further of the available balance in the net revenue account be transferred to reserve, making this £1,000, and a balance in hand of £631. 3s. 3d. The total capital spent was £14,190, and £3,150 had been repaid, so that the net capital was £10,850, against £11,318 last year. The total revenue for the year was £3,670, an increase of £167. The introduction of metal filament lamps was largely accountable for the smallness of the increase. Total expenses were £2,059, and the gross profit £1,600. Interest absorbed £410, repayment of capital £575, discount and bad debts £180; the net profit was £299. The number of consumers had increased from 329 to 381.

Spain.—The Societa Anon. Tranvias de Valladolid has been granted permission to electrify its lines.

Sunderland.—On Wednesday the Corporation adopted a recommendation of the Electricity committee to substitute electric lamps for 266 existing gas lamps upon the route of the electricity mains.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,035 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

The cost for conversion will be £465. 10s., and the annual cost of lighting and maintenance will be the same as hitherto paid for gas.

Torquay.—In reference to the attitude of the Board of Trade towards the local tramways, which are worked on the Dolter surface contact system, it must be remembered that the Dolter system has been employed under provisional certificates granted by the Board.

Although the working of the tramways, both for speed and smoothness of running, has been satisfactory to the Council, yet the defective studs per month reported to the Board have been considerable, though the number of "live" studs has not been in excess per mile per week of that obtaining in other places where surface contact systems are in operation. Representations made by my Council to the Board of Trade from time to time, expressing satisfaction with the working of the tramways, have resulted in the certificate being re-issued half-yearly, but on the occasion of the last renewal (in October, 1909), after again considering the representations of the Council on the subject, an order sanctioning the use of the Dolter system was issued by the Board for a further period of 12 months with an intimation that it was granted on the understanding that if no substantial improvement was shown by the returns in regard to live studs during the next six months the company would then have notice that at the end of the remaining six months no further sanction would be given to the use of the Dolter system. As stated in our last issue (p. 256) the Board have now intimated to the company and the Council that, as there has been during the last six months no substantial improvement in the working of the system, as shown by the large number of defective studs still obtaining on the tramways, they will not further renew their sanction to the use of the system, and the Council are considering this ultimatum in conjunction with the company. We are informed that the discontinuance of the present means of propelling the trams will be much regretted locally, as the fact that the cars would be driven by a surface contact system of electric traction had great weight with the Council in consenting to the original introduction of tramways into the town.

At the meeting of the Corporation on Monday, the chairman of the Tramways committee (Mr. E. Pike) made a lengthy statement as to the present position. With reference to the number of live studs, the company had made a return for 12 months showing that there were from 40 to 60 a month, and when it was considered that there were 6,000 or 7,000 studs, that was only 1¼ per mile per month. That did not seem many, but in the opinion of the Board of Trade it was too many. As to dead studs, that was a large item. It might be calculated as anything from 1 in 4 to 1 in 6, and it was here that the flashing took place. The committee had done everything in their power to get the existing defects rectified. They would be sorry to see the present system done away with. The tramway company said they had done everything possible. The only way to keep down live and dead studs was to have a patrol and stud repairer every quarter of a mile, and a staff of men in the sheds for making and repairing the studs, and that, from the company's point of view, was an impossibility. The company offered to adopt for the proposed extension the trolley system. The present tramways, regarded as a commercial undertaking, did not pay, and the company wanted to equip something that would pay, and he did not know that the Council would put any obstruction in their way so long as the new system did not disturb the amenities of the town. There were two courses open to the company; one was to give up the undertaking, the other to go to arbitration. The Council wanted neither. He doubted whether the public would agree to give up the trams. The company were carrying 10,000 passengers at 1d. fares per day. The committee were told that the present system of trams cost 9d. per mile to run, against average receipts of 7d. They were told that they would get a better service with the overhead system, and that there would be a reduction in cost of current. Last year the company paid the Corporation £5,500 for current, and their income was about £15,000. He moved that the matter be sent back to the committee with instructions to make the best arrangements they could with the tramway company, who would do the very best for the Council and the town.

Mr. J. SMERDON said if they could get from the company their bottom price for their system they would be able to consider whether it was desirable to purchase it.

The motion was carried.

Tottenham.—The Metropolitan Electric Tramways (Ltd.) have informed the Council that negotiations are proceeding in connection with the Tottenham and Walthamstow light railway.

Transvaal Power Scheme.—In the directors' report of the Tweefontein Colliery (Ltd.) it is stated that arrangements have been practically concluded with the Transvaal Hydraulic Power Synd. in regard to the erection of a large electric power station and chemical factory on the colliery company's property. Under the terms of the arrangement, a minimum of 25,000 tons of small coal and second-class coal (the latter of which at present is not being mined) per month would be purchased for the power station

Digitized by Google

Uruguay.—A bill has been introduced in Parliament to grant Mr. Edwin Steer a 90 years' concession for the construction of the Ferrocarril Expreso Eléctrico Montevideo-Buenos Aires and for carrying out other public works and equipping a hydro-electric generating station. The railway will extend from Montevideo to Colonia, whence a steamship service will connect with Buenos Aires.

Watford.—In view of the fact that Bradford and Leeds Corporations have obtained Parliamentary powers to employ railless traction systems, the Council consider it desirable that the construction of the proposed light railways in Watford be deferred.

Negotiations are proceeding with the North Metropolitan Electric Power Supply Co. as to supply of electricity in Munden and Hansteads.

West Ham.—Tenders are to be invited for wiring the new boys' department of the West Silvertown School.

Westhoughton (Lancs.).—The Council have authorised Atherton Council to supply electricity to certain persons in this district.

Wimbledon.—Councillor Dudley Stuart, M.I.E.E., has been appointed chairman of the Electric Lighting committee in succession to Ald. A. Holland, J.P., resigned.

Winchester.—The Assize Courts magistrates' room and the offices of the County Treasurer are to be wired, and the question of lighting the Court Hall is also under consideration.

Wireless Telegraph Notes.—Interesting developments are stated to be taking place in the establishment of a wireless telegraphic service in the Straits Settlements and in Venezuela. With regard to the former, plans are in progress to connect Singapore, Hong Kong, Bangkok and Yokohama. The company interested is an American one, and seeks a 25-year licence for the sole right to conduct wireless telegraph business, giving the Governments the privilege of purchasing at the end of 10, 15, 20 or 25 years. The company propose to instal at Hong Kong a station equal to their station in New York, which will be capable of communication with Yokohama and Shanghai on the north and Singapore on the south. As regards Venezuela, the Government has arranged for international telegraphic communication between Colombia, Ecuador, Peru and Venezuela. The Director of Telegraphs of Venezuela has been instructed to communicate with the Government of Peru with a view to extending the inter-continental service to Bolivia, Chili, and thence to the Argentine Republic. The Government of Venezuela, in connection with the Compania Anonima de Navegacion Fluvial y Costanera de Venezuela, has decided to establish wireless stations of the De Forest system at Pampatar, Coche and Araya (Margarita Island), and on board the "Venezuela" of the Navegacion Co.

The new service of time transmission by wireless telegraphy from the station on the Eiffel Tower, Paris, was duly inaugurated at midnight on Monday, signals being repeated at 2 minutes and 4 minutes past the hour, with (it is stated by "The Times") satisfactory results, the range being between 4,000 and 5,000 kilometres.

The Electrical Engineers (London Division).—The second annual athletic sports of this Corps were held on the London County Athletic Grounds at Herne Hill on Wednesday evening last.

These sports are in the nature of trials for the Territorial championships which are held later on in the year. Last year the Electrical Engineers came within one point of winning the championship for the highest aggregate of points obtained in the Territorial sports, and if the results of the other evening's events are to be relied upon, they should do just the necessary amount better this year. The times showed a great improvement, while the keenness of those entering was certainly better. A championship cup, presented by Major A. E. Le Rossignol, which is to be held by the company obtaining the greatest aggregate of marks on the events undertaken, was won by "C" Company with 28 points, "A" Company being second with 21 points.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Belfast.—The accounts of the electricity department for the year ended March 31 have been issued, and show a net profit of £11,040, against £8,282 in 1908-9.

Birmingham.—The accounts of the electric supply and tramways department (abstracted in our last issue) were submitted to the Council on Tuesday.

Mr. ELLAWAY, chairman of the Electric Supply committee, moved that authority be given for the provision of additional plant and the provision of a sub-station at Harborne at a total cost of £143,250. In 1907 (he said) they had voted a certain sum for prospective extensions to meet requirements for the three succeeding years. The committee now sought to make preparation for a further period. None of the work for which authority was sought would come into commission before the autumn of next year, but they had to get the sanction of the L.G. Board, and some portion of the machinery would require six months to build. The output of the department had been growing by leaps and bounds, especially for lighting and power. The increase in 1907 was 1,750,000 units, in 1908 2,500,000, in 1909 3,000,000 and last year 4,500,000 units. The forecast of the committee had been exceeded. While their capital had been increased by about 15 per cent., the output had increased about 50 per cent., and during the three years 1908-10 they would have paid £20,000 to rates, besides £16,000 to renewals fund and £62,000 for writing off obsolete plant. They had also made concessions to consumers in reduced charges equal to about £11,000.

The resolution was agreed to and the committee were authorised to appoint a secretary to the department at a salary of £600 per annum.

The chairman of the Tramways committee (Mr. HARRISON BARROW) thought the results of the past year's working of the tramways very satisfactory. The gross revenue from the city lines showed an increase of £13,791, and outside the city of £4,022. The receipts per car-mile had increased from 11·13d. to 11·63d. Economy had been effected in the use of electric current by affixing meters to a number of cars, and it was proposed to see what further could be done. The reduction in the hours of employés increased the expenditure nearly £8,000. The surplus to be transferred to relief of rates was £32,914, compared with £29,490.

Blackburn.—The traffic receipts of the Corporation tramways for the year ended March 25 were £55,613 (against £56,569 in previous year), parcels receipts £1,616 (against £1,477), and total receipts £59,285 (against £60,132).

Working expenses were £37,742, against £43,503; and the gross profit was £21,543, against £16,629. Interest absorbed £6,831, repayment of loans £6,080 and contributions to sinking fund £7,983. The net profit was £453, against a loss of £4,804 in 1908-9. The car miles run were 1,065,451 (against 1,132,023), the passengers carried 10,439,450 (against 10,737,528), and the receipts per car mile 12·59d. against 12·04d.

Brighton.—At the meeting of the Corporation last week the report and accounts of the tramways department for the year ended March 31 were approved.

Coun. BUTT-THOMPSON, chairman of the Tramways committee, said the year's revenue was £51,359, against £47,809 in 1908-9, an increase of £3,550. Total expenses were £37,069 against £36,670. There had been an increase in cost of renewals, and a slight increase in wages. Permanent way cost £4,005 compared with £3,549. The car mileage run increased by 21·101, and they had carried 724,992 more passengers. There had been a trading profit of £14,289, an increase of £3,151, and the net profit was £1,190, compared with a loss of £2,420. The total debt was £246,756, and the reserve fund £4,613. 18s. 10d.

The report of the engineer and manager (Mr. Wm. Marsh) states that there were 10 broken axles, compared with 25. There are 71 of the largest size in use, some of which have been running 3½ years, but not one of these has been broken. Increasing their diameter to 4⅜ in. appears to have had the desired effect. Price of current has been reduced from 1·5d. to 1·35d. Total revenue per car mile was 10·99d. (against 10·34d.) and working expenses (including power) were 7·86d. (against 7·93d.). Current used per car mile was 1·71 (1·7) units.

Burton-on-Trent.—The capital expenditure of the tramways department at March 31 was £106,000, an increase of £360 on the year.

The year's revenue was £14,044 (against £14,183), in addition to £932 £926) from the Midland Railway Co. for running powers. The trading deficit was £1,756 (£1,747). £1,496 has been placed to reserve, compared with £1,000 in the previous year. Total receipts per car-mile (exclusive of M.R. cars) were 7·87d. (7·97d.), and operating expenses were 6·27d. (6·37d.). Units used per car-mile on Corporation cars were 1·27 (1·26). Miles run 428,219 (425,843).

Crewe.—The income of the electricity department for the year ended March 31 was £7,899, including £4,111 from sale of current by meter and £3,588 from public lighting.

The expenses came to £3,733, and included £2,179 cost of generation, £164 for distribution, £379 for public lighting, £428 for rents, rates and taxes, and £500 for management expenses. The gross profit was £4,166, and after taking into account interest, &c. (£136), and paying interest on loans (£1,248), sinking fund and loan instalments repaid (£1,834), there was a balance profit of £1,220, of which £500 was transferred to reserve, £500 in relief of rates and £683 to meet expenditure in excess of loans sanctioned. Capital expenditure is £55,058, increase £903. 10s. on the year. 745,345 units of electricity were generated: 301,743 units were supplied for public lighting and 334,532 sold to private consumers. There are 34 arcs and 743 incandescent posts for public lamps, and the maximum supply demanded was 440 kw.

Devonport.—At the meeting of the Electric Power committee last week the chairman (Ald. J. B. Love) stated that the gross profit for the year ended March 31 was £7,467. 18s. 10d., and after paying interest and sinking fund the net profit was £1,010. 19s.

Ald. LOVE said the trams on the extension lines were stopped for over nine months of the year, which meant a drop in the sale of current of 122,717 units, representing £715. 12s. In spite of this, by extended business in other directions, the income had reached within £217. 14s. 11d. of that of 1908-9. A saving of £627 had been effected in the cost of generation as a result of the use of mechanical stokers. 42 new consumers and a number of extensions were added during the year, representing an equivalent of 2,875 8 c.p. lamps. In 24 cases the work of installation was carried out by direct labour of the department, and 18 by local contractors. The sale of current to the Devonport & District Tramway Co. produced £5,384. 4s. 2d.; Plymouth, Stonehouse & Devonport Tramway Co., £2,353. 8s.; private consumers (in Devonport) £4,153. 12s. 5d.; in Stonehouse, £3,889. 5s. 11d. The committee have placed the £1,010. 19s. to reserve and renewals fund, and have

Digitized by Google

decided to recommend the Council to reduce the price of current for lighting by ¼d. per unit (from 4d. to 3¾d.) The reduction represents £450 per annum.

Exeter.—The accounts of the electricity undertaking for the year ended March 31 show a surplus of £2,736. 18s. 8d.

About 100 new consumers were connected during the past year, and the units sold (1,413,762) increased by 43,500. The revenue from general lighting showed little change owing to increasing use of metal filament lamps. The accumulated profits and reserve amount to £7,416. In the past year's accounts 5 per cent. was allowed for depreciation of machinery, 2½ per cent. on mains and services, 6 per cent. on transformers and motors, and 5 per cent. on meters, instruments, stores and tramway generators.

The surplus on the tramways is £463. 19s. 2d., after wiping out the deficiency of £131. 7s. 10d. on the previous year. The car miles run were 424,873. £463. 19s. 2d. was placed to reserve and renewals.

Georgetown (Penang).—The report for 1909 of the engineer and manager of the municipal electric supply and tramways departments (Mr. Orlo V. Thomas) states that the capital expenditure of the electricity department during the year was $58,746 (£6,609).

It is stated that the generating station was 8 in. under water on Sept. 15, during the memorable floods, and the station had to be temporarily shut down. Additions to the plant, &c., during the year included a 300 kw. Allen-Westinghouse steam dynamo, a Babcock boiler to evaporate 8,500 lb. of water per hour, condensing plant, pipework, a Weir boiler feed pump and Ledward-Körting ejector condenser and pipework and Westinghouse switchboard extensions. All the remaining 16 c.p. carbon lamps used for street lighting were replaced by 50 c.p. metal filament lamps, and at the end of the year there were 43 arc and 369 50 c.p. metal filaments in use for public lighting. Total units sold were 674,140 (compared with 562,322 in previous year); revenue was $113,230 (£12,739), increase $19,013 (£2,139); expenditure was $67,633 (£7,606), increase $1,878 (£211). Generation and distribution costs were 8·04 cents (2·17d.), a decrease of 1·29 cents (0·348d.); and total costs 10·03 cents (2·708d.), decrease 1·67 cents (0·45d.). After meeting capital charges there was a net profit of $1,961 (£221).

Capital expenditure of the tramway department during the year was $18,665 (£2,100). Revenue was $65,382 (£7,355), compared with $69,579 (£7,828). Operating, power and general expenses were $60,265 (£6,780), an increase of $5,081 (£572). Gross profit was $5,117 (£576). The net deficit was about $9,000 (£1,025). The electrical equipments of the cars, supplied by the British Thomson-Houston Co., have given great satisfaction, and none of the motors have failed. 2,040,047 (2,236,097) passengers were carried and 281,413 (285,771) car-miles run.

Grimsby.—The total capital expenditure of the electricity department at March 31 was £102,318, an increase of £2,454 on the past year.

The annual receipts were £19,487, including £8,993 from sale of current by meter, £3,926 from the G.C. Railway, £3,044 from the tramway company, £1,190 from sale of current to the Admiralty and £1,714 from public lighting. Total expenses were £9,380. Allowing £63 for bad debts, the gross profit was £10,043, and after meeting interest (£3,276) and instalment of loans (£2,879), there was a net profit of £3,867, against £3,184 in 1908-9. 2,350,869 units were sold (893,660 for private lighting and power, 748,892 to the G.C. Railway in bulk, 501,321 for traction, 132,920 for public lighting and 74,076 to the Admiralty). The equivalent of 84,705 8 c.p. lamps is connected for private lighting and 1,665 for public lighting; total 86,370 8 c.p. against 78,934. 106 new consumers were connected during the year, the largest number added in any year since the start of the undertaking. The maximum load was 1,248 kw., against 1,225 kw.

In his report, the borough electrical engineer (Mr. W. A. Vignoles) states that there was an increase of 9 per cent. in the units sold for private lighting, and, as the increase in the number of lamps connected was in about the same proportion (9½ per cent.), it is evident that the majority of the consumers have now changed from carbon to metal filament lamps. The increase in the demand for energy for power was equal to 36 per cent., against 24 per cent. in 1908-9. There are 162 motors, representing an aggregate of 1,065 H.P. connected. Of these 33 (aggregate 395 H.P.) are supplied with electricity on the time-switch or restricted-hour system. Total generation costs were equal to 0·607d., an increase of 0·015d., mainly due to increased cost of repairs, and the total working costs were 0·921d., an increase of 0·046d., chiefly attributable to increased rates and taxes. £500 has been allocated to relief of rates, and the balance of the net profit (£2,259) has been transferred to reserve.

Mr. Vignoles states that the amount sanctioned by the L.G. Board for mains and services has now been expended, and an application for sanction to a further loan will shortly have to be made. At the recent inquiry the inspector intimated that money borrowed for services in future would have to be repaid in 15 years, and under these circumstances Mr. Vignoles thinks his committee should consider the question of paying for services out of revenue.

Huddersfield.—The accounts of the electricity supply department for the year ended March show capital expenditure £225,641 (increase £19,401).

The total amount borrowed is £214,515, and the amount of loans repaid and accumulated redemption fund is £65,654. The annual revenue was £32,963 (compared with £31,614), gross profit £13,133 (£12,014), and net surplus £711 (£550). Units sold were 3,829,681 (2,462,046). There are 3,200 (2,843) consumers and 294,824 (244,163) equivalent 8 c.p. lamps connected.

South Shields.—The Council are recommended to increase the salary of the tramways manager (Mr. L. E. Harvey) from £250 to £300, and then by annual increments of £25 to £350 per annum.

The report and accounts of the working of the tramways department for the year ended March 31 last have been issued.

The traffic revenue was £29,062 and the total receipts were £29,777. The working expenses came to £18,895 and the gross profit was £10,882. Interest required £5,748 and sinking fund £3,484, and the net balance (£1,650) has been transferred to reserve. 7,273,776 passengers were carried and 807,317 car-miles run. The gross capital expended is £171,863. The number of units of energy consumed was 1,070,343 (1·326 per car mile) and the bill for electric current shows a reduction of £917. 10s. 4d., a portion of which was due to the use of meters upon cars.

West Hartlepool.—The total revenue of the electricity department for the year ended March 31 was £15,538, including £14,340 from the sale of electric current from private and public lighting.

Working expenses were £8,650 and gross profit £6,888, and after paying interest (£2,476) and sinking fund, &c. (£3,297), there was a net profit of £1,128. The year's expenses were increased by £250 additional for coal owing to the Durham coal strike and by £284 law charges in connection with the arbitration proceedings re the Kitson clause. There are 724 lighting consumers (against 687) and 69 power consumers (54), a total of 793 (741), representing the equivalent of 123,275 8 c.p. connected (113,116). There are 223 motors, of an aggregate of 1,957 H.P., against 211 motors of 3,863 H.P. 2,387,222 units were generated; 1,998,508 units were sold to private consumers and 59,685 were supplied to the public lamps (39 arcs and 26 incandescents). The total maximum supply demanded was 1,070 kw. Works costs were 0·75d. per unit sold (against 0·81d.) and the total costs (including interest and sinking fund) 1·61d., against 1·68d. The load-factor was 21·96, against 23·89 per cent.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

HAMMERSMITH (London) Council invite tenders for supply of h.t. sub-station switchgear. Specification, from of tender, &c., from the borough electrical engineer, Mr. G. Gilbert Bell, 85, Fulham Palace-road, Hammersmith, W. Tenders to the town clerk, Mr. H. Thompson, by 4 p.m. June 1. See also an advertisement.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited for supply of 1,470 opalescent arc lamp globes to the city of MELBOURNE. Specification, form of tender, &c., from the agents of the City Council (Messrs. McIlwraith, McEacharn & Co. Propty., Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon June 8. See also an advertisement.

Tenders are also invited for supply of 941,000 arc lamp carbons to the city of MELBOURNE. Tender form, specification, &c., from the agents (Messrs. McIlwraith, McEacharn & Co. Propty., Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by Friday, June 17. See also an advertisement.

Digitized by Google

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

BARNES Urban District Council invite tenders for supply of 4,000 yds. of 0·25 0·25 1·25 sq. in. triple concentric cable, paper insulated, lead sheathed and jute served, suitable for a working pressure of 660 volts, manufactured in strict accordance with the British Engineering Standards committee's specifications. Tenders to the Clerk to the Council, High-street, Mortlake, by noon June 14.

NEWPORT (Mon.) Electricity committee invite tenders for supply and erection of two 400 kw. motor-generators, three-phase to d.c.; one 600 kw. motor-generator, three-phase to single-phase; and one 'bus-bar three-wire booster. Specifications, general conditions and form of tender from the borough electrical engineer and tramways manager, Mr. H. Collings Bishop, Town Hall, Newport, Mon. Tenders to the Town Clerk by first post May 31.

COVENTRY Electricity committee invite tenders for supply, delivery and erection of a 1,250 kw. turbo-alternator, complete with surface-condensing plant, &c., four water-tube boilers (straight tube type) and two fuel economisers. Specification, general conditions and forms of tender from the engineer and manager, Mr. Geo. Tough, and tenders to the Town Clerk, Hay-lane, Coventry, by first post May 30.

The LIVERPOOL Overhead Railway Co. require tenders by 10 a.m. June 7 for 12 months' supply of electrical fittings, insulating tapes, iron and steel, ironmongery, oil and grease, packings, &c. Forms of tender, &c., from 31, James-street, Liverpool.

EDMONTON Guardians want tenders by 9 a.m. June 2 for supply of three-phase electric motors and accessories and cable connections for the workhouse, Upper Edmonton. Form of tender from Messrs. May & Hawes.

MIDDLESBROUGH Corporation want tenders by June 2 for stores for 12 months, including electric lamps, i.r. tubes, iron and steel, belting, oils, &c. Specification from Mr. R. V. Thompson, 42, Commercial-street, Middlesbrough.

EALING Corporation require tenders by noon July 4 for supply and erection of surface condensing plant, &c., at the electricity works. Specification, &c., from the Borough Electrical Engineer, Town Hall, Ealing.

MANCHESTER Electricity committee want tenders by 10 a.m. June 7 for 12 months' supply of stores, including carbons, dynamos, brushes, iron and steel, asbestos and rubber goods, oils, &c. Forms of tender from the Town Hall.

MANCHESTER Tramways committee want tenders by 10 a.m. June 7 for special (permanent way) track work. Specification from 55, Piccadilly, Manchester.

BATLEY Corporation require tenders by noon June 1 for a lighting and traction switchboard for the electricity works. Specifications, &c., from the Borough Electrical Engineer.

ST. ANNES-ON-THE-SEA Council require tenders by noon May 28 for a fuel economiser. Specification, &c., from the Electrical Engineer.

LEICESTER Corporation want tenders by noon June 9 for an extension of engine room, &c., at tramway power station. Specification from the Borough Surveyor.

Tenders will be received by Mr. G. T. Moore, 1 and 2, Foster-place, Dublin, until June 4 for electric installation at 67, Sackville-street, DUBLIN.

Tenders are wanted by 6 p.m. May 31 for new electric lift at Beckett Hospital, BARNSLEY. Plans, &c., with Messrs. G. Moxon & Son, 26, Church-street, Barnsley.

CORK Electric Tramways & Lighting Co. (Ltd.) require tenders for steam boiler, with superheater and electrically-driven feed pump.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zinc for batteries. Local representation is necessary.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

SYDNEY (N.S.W.) Council require tenders by 3 p.m. May 30 for switchboard for Pyrmont power house, and by 3 p.m. July 17 for house service fuse boxes. Specifications from the City Electrical Engineer, Queen Victoria Markets-building, Sydney.

COPENHAGEN Corporation want tenders by noon June 2 for supply of two 1,000 kw. converters or motor-generators. Specification, &c., from Elektrisk Station, Gothersgade, 30, Copenhagen.

The ITALIAN STATE RAILWAYS Department require tenders by June 5 for supply of seven electric motor pumps. Tenders to 16, Via Ludovisi, Rome. Only firms on Departmental list may tender.

Tenders will be received on June 10 at the Post Office, rue de Grenelle, PARIS, for supply of telephone cable.

The Military Telegraphs Department, PARIS, want tenders by June 14 for supply of 100 Morse instruments.

The Ministry of Public Works, Constantinople, want tenders by June 28 for a tramway concession for SALONICA.

Tenders will be received (up to 11 a.m. June 6) at the Royal Arsenals, SPEZIA and NAPLES, for supply to the Italian Naval Authorities of electric lamps and lamp stands in two separate lots. The total estimated value of the contract is placed at 32,000 lire (about £1,280), and a deposit of 1,880 lire (about £74) will be required to qualify tenders for lot 1, and a deposit of 1,330 lire (about £53) for lot 2. Only manufacturers of electric lamps will be allowed to tender. Applications for certificates of competency to the Director of Naval Construction at Spezia, Naples, Venice or Taranto not later than May 21. Copies of the specifications, conditions of tender, &c., may be seen by British firms at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Bristol Corporation have accepted the following tenders for annual stores, &c.:—

Sykes & Sugden, joint and junction boxes, £213. 13s. 1d.; General Electric Co., meters, £546. 4s.; Bruce Peebles & Co., 500 kw. converter for Underfall Yard sub-station, £1,230; Union Electric Co., Ship Carbons (Ltd.) and Oliver Arc Lamp (Ltd.), for arc lamp carbons at schedule prices estimated to amount in the aggregate to £655. 5s. 1d.

Heston and Isleworth Council have accepted the following tenders: W. Lacey, extension of engine room; Browett, Lindley & Co., 250 kw. generating set, &c. (British Westinghouse dynamo and British Thomson-Houston switch panel); Babcock & Wilcox, steam piping and Weir pump; Körting Bros., condensing plant; and Selson Engineering Co., machine tools.

London County Council have received nine tenders for wiring Camden-street schools, St. Pancras, N.W., the amounts varying from £206. 19s. to £552. 19s. The second lowest tender, that of E. Lawrance & Sons, at £251, has been accepted.

Southend Council have accepted the tender of the Railway & General Engineering Co. for 100 renewable manganese plates for the repair of rail joints at £1. 15s. each; and that of Nalder Bros. & Thompson for 66 current limiters at 15s. each.

Hampstead (London) Council recently placed an order with Willans & Robinson for a 350 kw. disc and drum type turbine, and Norwich Corporation for a 500 kw. turbine. Both machines are intended for working both with exhaust and high-pressure steam.

Llandudno Council have accepted the tender of the Chloride Electrical Storage Co. for re-plating batteries and for supply of paper and vulcanised cable, &c., at £501. 10s.

Southwark Electric Light committee are continuing their existing arrangements with the Union and the Sloan Electric Companies for supply of arc lamp carbons at £2. 18s. per 100 pairs, less discount.

Smethwick Education committee have accepted the tender of H. W. Ludlow for wiring work at the technical school.

The East Indian Railway Co. have ordered a milking booster from the Lancashire Dynamo & Motor Co., and electrically-driven high-lift pumps for their electrical department from Greenwood & Batley.

Government Contracts.—The following tenders have been accepted by Government Departments:—

Admiralty, Edison & Swan Co., Evered & Co., General Electric Co., and W. McGeoch & Co., lampholders; India Rubber, Gutta Percha & Telegraph Works Co., gutta percha. *War Office.*—Craven Bros., electric cranes; Lancashire Dynamo & Motor Co., motors, &c.; Siemens Bros. & Co., extension of electricity supply; Foote & Milne, electric lighting of R.A.M. College, Millbank. *India Office.*—Siemens Bros. & Co., cables and electrical stores. *G.P.O.*—Creed & Co., telegraph apparatus; Johnson & Phillips and Western Electric Co., paper core cable; General Electric Co., electric light fittings. Peel-Conner Telephone Works and Gent & Co., telephones; T. Bolton & Sons, British Insulated & Helsby Cables, Elliott's Metal Co., R. Johnson & Nephew, Shropshire Iron Co., F. Smith & Co., and J. Wilkes, Sons & Mapplebeck, h.-d. copper wire; A. Sauvee & Co. and Spencer & Co., endless band conveyors for new G.P.O. building, London, E.C.

Digitized by Google

Commonwealth Tenders.—The following tenders have been accepted by the Postmaster-General's Department :—

Victoria.—Western Electric Co. for 52 pair cable; British Insulated & Helsby Cables, five 100 line switchboards; Drew & Poole, 100,000 porcelain insulators; R. Johnson, Clapham & Morris, g.i. wire; J. A. Newton & Co., telegraph switches, ebonite tubes and ear pieces, coin attachments, howlers and open-circuit condenser telephones; Lawrence & Hanson, metal filament lamps, "Linolite" carbon filament lamps and T.H. screw socket carbon lamps.

New South Wales.—W. T. Henley's Telegraph Works Co., switchboard cable; India Rubber, Gutta Percha & Telegraph Works Co., Q and I detectors; J. A. Newton & Co., dry cells; Lawrence & Hanson, conductor cords.

Queensland.—International Electric Co., condensers; Western Electric Co., wall and table telephones; J. Paton & Co., table telephones.

BUSINESS NOTICES.

On and after June 22 the Newcastle stores and offices of the Edison & Swan Co. will be at Swan's Buildings, St. James-street, Leazes Park-road, Newcastle-on-Tyne. Mr. H. Smith will remain manager of the branch.

The partnership between Jas. D. and John H. McCarthy and Geo. H. Nicholls (trading as G. Nicholls & Co.), electric and gas fitters, &c., Goldsmith-avenue, Portsmouth, has been dissolved. Debts by Messrs. J. D. and J. H. McCarthy.

The partnership between Fredk. W. Richardson and Johan D. Carlmark, electrical engineers, &c., High-street, West Bromwich, has been dissolved.

The partnership between F. W. Bridges and G. D. Smith has been dissolved, and Mr. Smith's business will be carried on, as hitherto, at the same address, 125, Finsbury-pavement, London, E.C.

Plant for Sale.—An 80 kw. Willans steam dynamo is advertised for sale.

Demand Indicators for Sale.—Torquay Corporation advertise for sale a number of demand indicators of various sizes from 3 amperes upwards, which may be inspected at the electric lighting station.

Lamp Agency.—A firm of British metal and carbon lamp manufacturers, at present able to produce 300,000 lamps per annum, and capable of extension, advertise that they desire to arrange with a wholesale factor house to take practically exclusive output.

Patents Development.—The proprietors of the following patents desire to enter into arrangements by way of licence and otherwise for exploiting and developing the same in this country :—

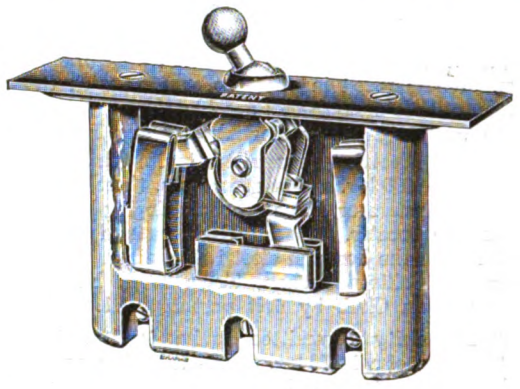
No. 17,601/1901, for "Improvements in apparatus and devices for controlling electric currents"; No. 15,243/1903, for "Improvements in means for automatically regulating electric currents generated by dynamos"; No. 16,962/1902, for "Improvements in electrical switches or cut-outs"; No. 17,314/1905, for "Improvements in automatic regulators or rheostats for electric currents." Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

Patent No. 10,187/05, for "Improvements in electric couplings." Applications to Messrs. G. F. Redfern & Co., 15, South-street, Finsbury London, E.C.

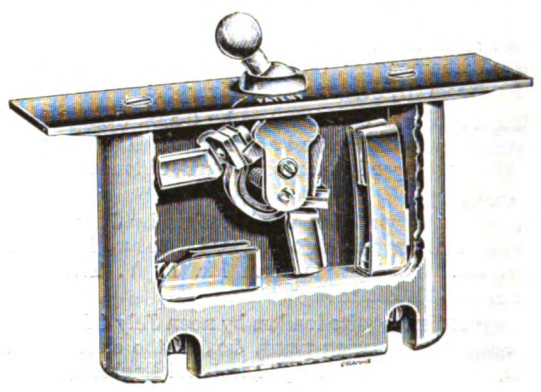
No. 12,210/1901, relating to "Electrostatic Separators." Applications to Messrs. Cruikshank & Fairweather, 65 and 66, Chancery-lane, London, W.C.

Patent Amendment.—Notice is given that Herr Willy Roos, engineer, of 368, Offenbacherlandstrasse, Frankfort-on-the-Main, Germany, seeks leave to amend the specification of letters patent No. 12,135/1907, granted to him for "Improvements in magneto-electric ignition apparatus." Particulars of the proposed amendment are set out in the "Illustrated Official Journal (Patents)" of May 19, and notices of opposition must be given at the Patent Office 25, Southampton-buildings, London, W.C., within one calendar month of that date. The agents for the applicant are Messrs. Cruikshank & Fairweather (Ltd.), 65 and 66, Chancery-lane, London, W.C.

"Klymax" Panel Switch.—Messrs. A. P. Lundberg & Sons have sent us a sample of their new two-way panel switch of 5 amps. capacity. This is a new type for flush work, to meet a demand for a narrow-pattern switch of minimum dimensions (the sample is purposely broken through to show construction). Considerable economy in space, labour and material is, it is claimed, obtained by its use. The switch movement adopted and the arrangement of the contact springs and blades are quite novel. Mica and porcelain are employed for insulating the current-carrying from other metal parts. The switch is supplied in two types, single-way and two-way, which are identical in size. All moving parts are enclosed in a porcelain casing, and the fixing lugs are covered by a brass front plate $3\frac{13}{16}$ in. by 1 in. Special fronts of other materials are also fitted to requirements. The method adopted allows the articles to be grouped into very small space, and one front plate of comparatively small dimensions can be made to serve for a number of switches. The break is quick and long, the contact arms being of the efficient knife-blade type entering double-contact springs. The switches can be fitted into suitable iron boxes to meet requirements. When



double-pole and intermediate switches are required, these are simply and neatly obtained by coupling the knobs of two single or two-way switches respectively by a short cylinder piece. Two-pin wall



connections of various gauges can also be arranged on the same porcelain parts, enabling combination sets to be made up in minimum sizes.

Tubular Osram Lamp.—We learn from the General Electric Co. that they are now making tubular Osram lamps of 16 c.p. similar to that shown in the accompanying illustration, for use on circuits of pressures between 100 to 125 volts, the price being 3s. 6d. The company anticipate a considerable demand for this new shape of lamp, as it is particularly adaptable to many popular fittings now in demand.

General Electric Co.'s Stand at the Japan-British Exhibition.—In the company of a number of pressmen, we paid a visit on Wednesday last to the General Electric Co.'s stand in the machinery hall at the Japan-British Exhibition. The opportunity has been taken to make a grand display of Osram lamps, and amongst the most interesting of the exhibits shown in this connection is a board on which are fixed a number of types of Osram lamps in candle-powers varying from 1 to 1,000, thus giving an idea of the wide range and general adaptability of this type of lamp.

We understand that on Whit Monday the stall was a great attraction to visitors and that the sale of Osram lamps is likely to materially benefit thereby. Another interesting exhibit, which is to be used in connection with Osram lamps, is a special line of glassware, by which it is claimed proper distribution of the light is obtained, while all glare is prevented. We have often spoken of the importance of this question, and are pleased to see that such a well-known firm as the General Electric Co. is taking the matter up in so thorough a fashion. The bait used in drawing the general public is an exhibit somewhat similar, but on a smaller scale, to that employed at the Olympia Exhibition in 1905. The mounting of Osram lamp filaments is carried on in full view of the public, who are mightily interested in the various processes, and there

Digitized by Google

are certain examples of glass-blowing, such as pigs, which also attract attention. The stand is surmounted by a sign displaying the benefits of Osram lamps, which is visible from the entrance to the Machinery Hall, and on Wednesday afternoon by far the greatest crowd was to be found round the General Electric Co.'s stand. We wish the company every success in their endeavours to gain the benefits of electric lighting for the public.

CATALOGUES, &c.

CHEAP ELECTRIC COOKING.—Messrs. F. A. Wilkinson & Partners forward a leaflet dealing with their economic electric cooker. The cooker is neat and compact, and is specially adapted for use with ordinary household utensils.

KALKOS TINNED TUBE WIRING SYSTEM.—The Sun Electrical Co. have forwarded a catalogue dealing very fully with the Kalkos system of wiring, which is now well known; its wide application shows that its merits are becoming fully appreciated among contractors and supply engineers. We advise our readers to procure a copy of the catalogue and to study the recent improvements that have been made.

METAL PARTS AND SUNDRIES.—The Specialities Supply Co., of Bermondsey, London, have put down plant by means of which they are able to turn out cheaply and quickly stamped, pressed or spun metal work of all kinds, as well as light gauge brass and copper tubes and nickel cases and boxes for scientific instruments and similar goods. The demand among electrical manufacturers for this class of work is large, and manufacturers will therefore be interested in the prices at which the Specialities Supply Co. can offer them.

EDISWAN ELECTRIC FANS.—At an appropriate moment the Edison & Swan United Electric Light Co. issue a catalogue illustrating and describing their electric fans. These are made in several types suitable for ceiling, wall, desk and porthole work.

THE IDEAL HOME.—From the South Metropolitan Electric Light & Power Co. comes a pamphlet giving an account of their Ideal Home at Catford. Illustrations of the various rooms furnished and apparatus employed are given, and the pamphlet is of general interest. The distribution of the pamphlet amongst prospective consumers should be of service to supply undertakings generally.

BANKRUPTCIES, LIQUIDATIONS, &c.

With reference to the notice appearing in our last issue (p. 257) regarding the voluntary liquidation of the Lepel Wireless Synd. (Ltd.) we are asked to state that the Lepel Wireless Synd. was only a subsidiary company, and that the contracts and business of that company will be carried on, as before, by the parent company (the Anglo-German Wireless Synd., Ltd.), the owners of the patents of the Lepel system of wireless telegraphy.

A receiving order has been made against Wm. Hy. Trentham, consulting engineer, 39, Victoria-street, London, S.W. The first meeting of creditors will take place on June 3 at Bankruptcy-buildings, London, W.C., and the public examination on June 28.

John Filmer Davie, electrician, lately of 10, Gt. Castle-street, London, W., has been adjudicated bankrupt.

The affairs of the Phosphor Bronze Co. (Ltd.) having been put in order, a dividend is to be paid to the creditors of the company. Claims to Mr. S. P. Child, 8, Frederick's-place, Old Jewry, London, E.C., by June 7.

Adjudication Annulled.—The adjudication has been discharged and the receiving order rescinded in the case of Edwd. Wm. Barton-Wright, electric therapeutic specialist, 1, Albemarle-street, Piccadilly, London, W., the judgment upon which the bankruptcy proceedings were based having been set aside by the High Court.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

COMPANIES' MEETINGS AND REPORTS.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—At the meeting last week Mr. E. Boulnois stated that the principal item included in the expenditure of 1909 (£42,500) was for extensions of mains. The total length of mains at the end of 1909 was nearly 255 miles. The demand for current for power had increased considerably. In view of the demand in the northern district of Calcutta it was imperative that the company should take steps to supply current, particularly as jute mill owners were considering a proposal to combine and establish their own plant. Mr. B. M. Jenkin (their consulting engineer) approved the proposal to erect a new station, but thought it advisable to carry out the work gradually. The question of lighting the streets electrically had been further considered by the municipality, and it was understood they had decided, as an experiment, to light 6 miles of streets in that way.

CALLENDER'S CABLE & CONSTRUCTION CO. (LTD.)—Mr. Hy. Drake, who presided at the meeting last week, said the value of the business done by the company during 1909 showed a considerable reduction compared with that of recent years. The results, however, could not be considered other than satisfactory.

Mr. T. O. CALLENDER (managing director) said 1909 was a year full of trouble and disappointment. It had been a period of the greatest possible trial to the management and to the board to get such a result as they had obtained. Various causes brought that about. Probably the first was the metal filament lamp, but they were beginning to find the advantage of that lamp, and it was really going to do them, as cable makers, all the good that they anticipated. Then, again, there had been an absolute want of confidence throughout the country which had hit them very hard. No one who had money was prepared to sink it in lighting schemes, tramways, or any companies using electricity, these having, unfortunately, been the prey of a good many people during many years past, with the result that no new enterprises were started and the business to be done was simply the extension of existing mains.

Digitized by Google

Things were better now than in 1909. They had already experienced a distinct improvement in the demand for cables, both at home and abroad. Their German company had been quite satisfactory. After due consideration it had been thought advisable to extend further the scope of the trade of the company by pushing a purely engineering business.

CAPE TOWN CONSOLIDATED TRAMWAYS & LAND CO. (LTD.)—The accounts show a debit balance of £941. 9s. 7d. for 1909, which, added to £1,228. 6s. 6d. brought forward, makes a total debit of £2,169. 16s. 1d. The Camps Bay tramways have worked at a loss of £1,559. 13s. 4d., a slightly improved result compared with 1908, which showed a loss of £2,232. 11s. 3d.

CITY OF BIRMINGHAM TRAMWAYS CO. (LTD.)—At the meeting last week Mr. E. Garcke said the position of the company might be described as unique. Notwithstanding that their lines were being gradually taken over by the local authorities, and that they were exposed to increasing competition from municipal tramways, their traffic receipts increased and their net profits showed an improvement compared with 1908. The total receipts were £172,031, against £164,607, and the net profit (after paying interest and preference dividend) was £38,516, compared with £35,977. They proposed to declare a dividend of 5 per cent. on the ordinary shares and a bonus of 5 per cent., making 10 per cent for the year.

DEUTSCH-UBERSEEISCHE ELEKTRIZITATS (A.-G.)—The directors' report for 1909 states that the share capital was raised from 72,000,000 marks (£3,600,000) to 80,000,000 marks (£4,000,000), and the debenture stock from 15,000,000 marks (£700,000) to 70,000,000 marks (£3,500,000). It is proposed to further increase the capital by 10,000,000 marks. The gross profit for the year was increased from 15,077,900 marks (£753,895) to 17,631,200 marks (£881,560) and the net profit from 7,648,100 marks (£382,400) to 8,113,500 marks (£405,600). The dividend, which has been 9½ per cent. since 1906, is raised to 10 per cent.

FIFE TRAMWAY, LIGHT & POWER CO. (LTD.)—At the meeting on Monday the chairman (Mr. Wm. Low) said that with little over half their tramways running for less than two months, the earnings were such that the Tramway Company was able to pay a dividend to that company amounting to £1,111. 2s. 8d. The contractors (Messrs. Balfour, Beatty & Co.) were entitled to the thanks of the shareholders for the satisfactory result attained. Their company had agreed to acquire all the shares of the Fife Electric Power Co. The directors were satisfied with the position of the Power Company's business, and they felt sure that it would make a substantial contribution to their revenue this year. The Power Company's plant at Townhill had been largely extended, and overhead transmission lines and underground cables were laid to enable it to cope with the tramway and other additional business. Sub-stations have been built at Cowdenbeath and Lochgelly, and coupled up to supply cables so as to conveniently supply Cowdenbeath and Lochgelly. The Parliamentary powers they had sought were likely to be granted. The Fife Electric Power Co. had made an arrangement with the Wemyss Tramways Co. whereby the latter was to take from the Power Company the whole of its supply of electricity, both for the existing Wemyss tramways and for any extensions that might be constructed.

IMPERIAL TRAMWAYS CO. (LTD.)—The directors' report for 1909 states that the gross receipts of the Middlesbrough, Stockton and Thornaby electric tramways amounted to £49,670. 3s. 10d., compared with £50,904. 19s. 8d. for the previous year. The number of passengers carried was 9,834,213, against 10,014,056. The net profit was £16,142. 1s 2d., compared with £16,871. 14s. The directors regret that by the non-receipt of income from their investment in the London United Tramways the Imperial Co.'s revenue account suffered depletion to the extent of £21,111, and that they are consequently precluded from recommending any dividend on the company's preference and ordinary shares. The net revenue account for the year shows an available amount of £16,747. 1s, and after payment of debenture interest for the year (£12,740. 12s. 6d.) there remains £4,006. 8s. 6d., which the directors consider it expedient should be carried forward.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—Owing to the destruction by fire of the greater part of the machinery of the Great Boulder Proseverance Gold Mining Co. (one of the corporation's largest consumers), the demand for power was not so large as in 1908, and the increased cost of fuel and water, also a reduction in the maximum price received for power, together with the extra expense incurred in handling the firewood in consequence of wood strikes, considerably reduced the profits of the trading for 1909. The preference dividend has been paid, and £4,000 placed to reserve for depreciation and renewals. In view of the larger amount of power required by the Great Boulder Perseverance Co. for their new plant, to put the corporation into a position to supply additional power under other contracts and maintain the usual standard of reserve orders have been placed for another unit of plant.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—Total receipts for 1909 were £108,182. 3s. 6d. Traffic receipts (£91,931. 14s. 1d.) show a decrease of £398. 13s. 8d., and working expenses a decrease of £5,136.7s. 2d. Deducting expenses (including £12,157. 13s. 10d. for interest), there remains £26,169. 15s. 8d., or, with £1,121. 3s. 11d. brought forward, £27,290. 19s. 7d., compared with £21,780. 18s. 6d. The directors recommend that £2,000 be placed to reserve for depreciation, £7,000 to general renewals account, and, after paying the preference dividend (£12,250), a dividend of 2 per cent. on the ordinary shares (4,900). £1,050. 19s. 3d. is carried forward. During the year £8,996 was expended on the improvement, renewal and repair of the permanent way, of which £5,406 was charged against revenue and £3,590 to general renewals account. Further important work is in contemplation for the improvement of the permanent way, and additional provision for this purpose out of the year's profits is recommended.

TYPEWRITING TELEGRAPH CORPN. (LTD.)—The report for the 13 months ended Dec. 31 last states that the balance to debit and profit and loss account has been increased by £321. 13s. 9d. The corporation has not been in a position to pay debenture interest since June, 1907, and the directors regret that they are obliged to recommend the shareholders to pass a resolution for the liquidation of the company.

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

"CEDES" ELECTRIC TRACTION (LTD.) (109,698.)—Reg. May 18, capital £2,000 in £1 shares, to carry on the business of electricians, electrical engineers, manufacturers of and dealers in motors, carriages, tramcars, locomotives, &c. Private company. Reg. office, 15, Cockspur-street, London, S.W.

ELECTRO CHLORINATION SYND. (LTD.) (109,699.)—Reg. May 18, capital £50,000 in 48,000 preferred ordinary shares of £1 each and 40,000 deferred ordinary shares of 1s. each, to acquire and lay down a working plant for the reduction of ores and the refinement of metals by new processes in chlorination and electrolysis, to carry on the business of miners, smelters, metal workers, &c., and to adopt an agreement with H. W. Couzens. Reg. office, 39, Victoria-street, Westminster, S.W.

MORTGAGES AND CHARGES.

GELL TELEGRAPHIC APPLIANCES SYND. (LTD.)—Mortgage, dated April 29, to secure £1,600, charged on certain patents and inventions and the syndicate's general assets. Holders. C. M. Gonne, Mrs. J. Gonne and H. Gonne.

LANCASHIRE DYNAMO & MOTOR CO (LTD.)—Issue on March 21 of £100 debentures, part of a series of which particulars have already been filed.

NORTHWOOD ELECTRIC LIGHT & POWER CO. (LTD.)—Particulars of £5,000 debentures, created April 6, have been filed, the amount of present issue being £1,725. Property charged, company's undertaking and property. No trustees.

CITY NOTES.

MEMORANDA (May 26).—**Bank rate 4 per cent. (since March 17, 1910). Price of silver,** 24⅛d. per oz. Consols 82⅛—82⅜ for money and for account. **Consols Pay Day, June 1; Stock and Shares Continuation Days, June 8 and 27; Ticket Days, June 9 and 28; Pay Days, May 27 and June 10; Mining Shares Carry Over Day, June 7.**

PRICES OF METALS (London).—*Copper*, cash, 55⅞; three months, 57⅛. *Lead*, English, 12⅜—13⅛; foreign, cash, 12⅛; three months, 12⅝. *Spelter*, 22. *Tin*, English, 149½—151½; foreign cash, 150⅝; three months, 151⅞. *Iron*, Cleveland, cash, 49/10½, and three months, 50/9½

COMPANIES STRUCK OFF THE REGISTER.—The following were struck off the Register of Joint Stock Companies on May 24:—

Automatic Telephone Co. (1903), British Electric Separating Co. (reg. April 20, 1904), Carbon (New) Synd., "Everyday Electricity" Publishing Co., Garcin Renault Electric Cars & Accumulators, Kryptol Synd., Northern Electrical Supply Stores, Reliance Electric Co.

HINDHEAD & DISTRICT ELECTRIC LIGHT CO. (LTD.)—At the meeting last week a balance dividend was declared at the rate of 6 per cent., making 5½ per cent. for 1909.

METROPOLITAN DISTRICT RAILWAY CO—The following changes have been made consequent upon Sir George Gibb's appointment as chairman of the Road Board: Mr. Albert H. Stanley has been elected a director and appointed managing director; Mr. J. Carter, late secretary, becomes assistant to the managing director; and Mr. W. E. Mandelick, secretary of the Underground Electric Railways Co. of London and of the Allied Tube Railways, has also been appointed secretary of the District Railway.

SHANGHAI ELECTRIC CONSTRUCTION CO. (LTD.)—The accounts for the 18 months to Dec. 31 last show a loss of £949, before making provision for depreciation.

SOUTH STAFFORDSHIRE TRAMWAYS (LESSEE) CO. (LTD.)—The accounts for 1909 show, after providing for debenture and loan interest, a loss of £1,493, converting the credit balance brought forward into a debit of £986.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have appointed June 10 a special settling day in and have granted a quotation to a further issue of £2,500,000 4½ per cent. first and general mortgage 30-year bonds (London issue) of the *New York Telephone Co.* Quotations have also been granted to 70,000 £5 fully-paid ordinary and 14,000 £5 fully-paid 6 per cent. cumulative preference shares and £700,000 5 per cent. first debenture stock of the *Para Electric Railways & Lighting Co. (Ltd.)*. The committee have been asked to appoint special settling days in and grant quotations to scrip for £250,000 5 per cent. debenture stock of the *Metropolitan Electric Tramways (Ltd.)* and scrip, fully and partly paid, for £250,000 5 per cent. first mortgage debentures of the *Vera Cruz Electric Light, Power & Traction Co. (Ltd.)*.

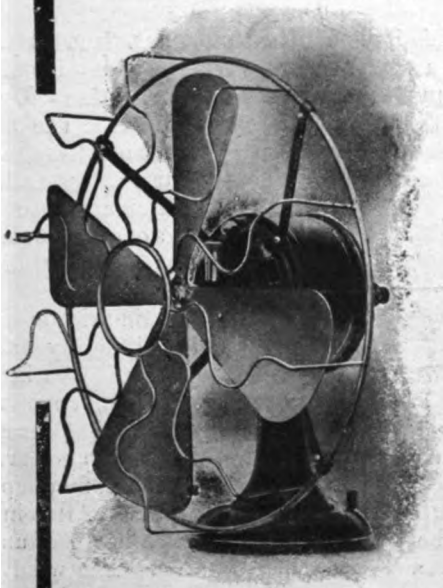
Simplex Fans

WHEN Buying Fans or Small Motors, remember these Facts about SIMPLEX FANS:—



1.—Especial care has been taken in the design of even the smallest mechanical and electrical details in order to make them unequalled in efficiency and silent running.

2.—Current consumption has been reduced to a minimum without decreasing the air delivery

3.—Prices range as low as 33s. each, subject, and you are certain of obtaining best possible value for money.

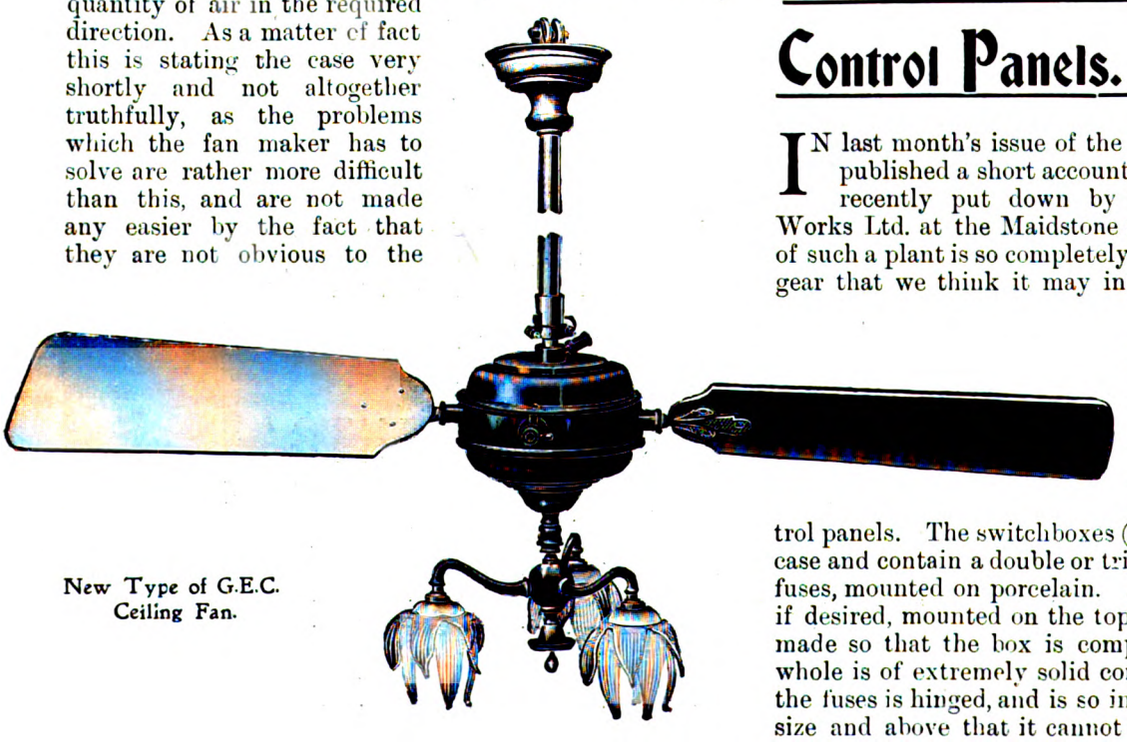
G.E.C. Fans.

AT first sight the problems which have to be faced by the fan designer would appear to be slight. It would seem that he has only to design a motor to run more or less continuously without overheating and so to arrange his blades that they distribute a certain quantity of air in the required direction. As a matter of fact this is stating the case very shortly and not altogether truthfully, as the problems which the fan maker has to solve are rather more difficult than this, and are not made any easier by the fact that they are not obvious to the casual observer. It is all very well to design fan blades which shall just churn up the air and give the false idea that they are doing something towards ventilating a room, but these revolving falsehoods are almost certainly, sooner or later, to be found out, with a result that is not likely to be pleasant to the firm that has supplied them.



New Type of G.E.C. Ceiling Fan.

The General Electric Co. have for some time been well-known makers of electric fans of all descriptons, from those suitable for standing on the desk or table and ventilating a small room to those for dealing with large quantities of air, such as are required for supplying mines and other places where no natural circulation is available. This experience is of great use to the General Electric Co., for while keeping in broad outline the same design of fans from year to year they are able to improve them in details in accordance with the demands of practice. In the accompanying illustration we show an alternating-current ceiling fan, which has been brought out this season for domestic purposes. A disadvantage, which has always attended the use of fans driven by alternating-current motors is the hum which is set up in the motor itself. To overcome this difficulty has always been the constant endeavour of fan manufacturers, and it is claimed that in this new fan the running is noiseless, and it is in fact the most silent-running alternating-current fan on the market. The lighting pendant, which is shown in the illustration, is, of course, not absolutely new as applied to fan design, but the combined fitting thus made up should have a wide sphere of usefulness. We are asked by the General Electric Co. to say that they would be pleased to show this fan in operation to any engineer calling at their show rooms in Queen Victoria-street.

The General Electric Co. have designed an electrically-driven punkah which, it is claimed, gives this flick which is so much to be desired. This is a distinct feature of the apparatus as against those placed on the market in the earlier days. It is interesting to note in this connection that a great economy in energy consumption is obtained by the use of this apparatus, which, it should be stated, is known as the "Bandy" punkah.

Switchboxes and Motor Control Panels. . . .

IN last month's issue of the Industrial Supplement we published a short account of the pumping installation recently put down by Siemens Brothers Dynamo Works Ltd. at the Maidstone sewage works. The success of such a plant is so completely dependent on the regulating gear that we think it may interest our readers to have a few particulars about some new lines of starters that this firm has recently brought out.

These comprise open, protected and totally enclosed starters, weatherproof switchboxes and motor control panels. The switchboxes (Fig. 1) consists of a cast-iron case and contain a double or triple-pole switch and cartridge fuses, mounted on porcelain. An ammeter can be supplied, if desired, mounted on the top of the case. All joints are made so that the box is completely weatherproof and the whole is of extremely solid construction. The window for the fuses is hinged, and is so interlocked in the 100-ampere size and above that it cannot be opened whilst the switch

Digitized by Google

is closed, and, conversley the switch cannot be closed while the window is open. The fuses are of Messrs. Siemens' well-known "Zed" type, provided with an indicating device which shows at a glance when a fuse has blown. All live parts are completely enclosed, making it impossible to receive a shock accidentally when replacing a cartridge, and no arcing or flashing occurs when a fuse burns out.

The switch has a quick-break action and each pole is mounted on a seperate porcelain. The boxes are so

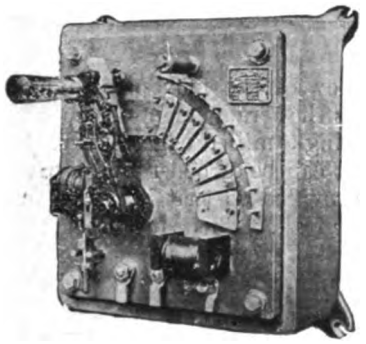


Fig. 1.—Open Type Starter with Step-by-Step Slow Motion Gear.

arranged that 2, 4 or 6 cables can be led into the box from above or below, except when an ammeter is used, in which case only two cables can be led in from the top. The boxes are stocked undrilled and are drilled to suit customers' requirements, and cable glands and packing can be supplied.

The motor starters are mounted on slate base; the contacts are renewable and of ample area and section; overload and no-voltage releases are fitted. The centre spindle is provided with a ratchet and the overload release with a pawl, and these two come into operation if the motor is switched on too rapidly and prevent further movement of the brush. A patent step-by-step slow motion gear can be fitted to these starters. In this gear the switch is moved

Fig. 2.—Weatherproof Switchbox with Ammeter.

Fig. 3.—Weatherproof Motor Control Panel.

sharply from one contact to the next, but retained at each step for a short time to enable the motor to come up to speed. The advantages of such a device as this scarcely need to be pointed out. This gear is shown in the illustration (Fig. 1).

The motor-control panels already mentioned (Fig. 3) are a combination of the switchbox and starter already described, mounted on a cast-iron pillar. They are specially constructed to withstand rough usage and bad weather.

Crompton Moving Coil Instruments.

THE question of instruments should not be without interest to the electrical engineer, for on their correctness depends the validity of all his results, both economical and technical. It will, therefore, not be inopportune to give some details of a series of instruments of the moving coil type made by Messrs. Crompton & Co. for continuous-current work.

As regards general design, it may be mentioned that great attention has been paid to standardisation. All the instruments can, it is claimed, be left in circuit continuously without heating and without affecting their accuracy. All volt indicators are designed to give either their normal or maximum reading with a current of 0·015 ampere, while in the case of ammeters a full scale reading is given when the P.D. across the instrument terminals is 0·075 volt. The indicating instruments of all voltmeters having external resistances are therefore interchangeable, and any ampere indicator can be used with any shunt. If, however, indicators are used with resistances or shunts of different rating, the scale readings must of course be multiplied by a constant.

This complete standardisation not only allows great economies to be effected in manufacture, but it also facilitates the subsequent verification of the instrument. Only one controlling spring is used, and this is entirely independent of the circuit. With regard to appearance, attention may be called to the absence of wide flanges on the back of all the instruments. This arrangement, it is

claimed, enables longer effective scales to be used compared with the space occupied.

Electrically, the instrument consists of a horse-shoe permanent magnet with mild steel pole pieces. The pole pieces are constructed in a solid block with a pair of brass cheeks and are machined all over before being placed in the permanent magnet. The hole between the pole pieces is bored to receive the movement plug and the annular gap between the pole pieces and this core is the space in which the coil moves. The moving part consists of wire, wound on a copper former, and Fig. 1 shows the method of mounting it upon the magnet core. The parts GG are brass studs fixed in the core to centre it when placed in the pole piece block. The whole piece shown in this figure is termed 'the movement plug." The holes in the pole piece blocks, and the movement plugs, are made to gauge, so that each movement plug fits any magnet, these parts being mechanically interchangeable in all instruments.

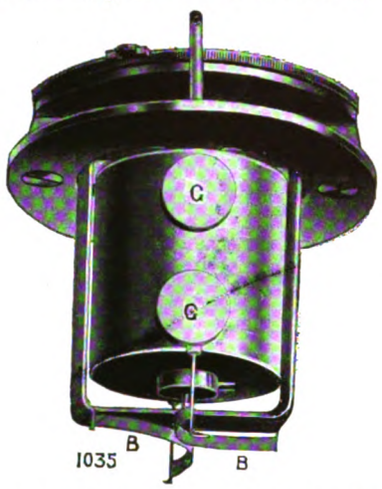

Fig. 1.—Method of Mounting Moving Coil.

Fig. 2 is a view of the movement plug seen from the front, and shows the arrangement of the controlling spring. The ring R, having a milled edge, is carried in a supporting bridge so that it can be turned round by hand. Two holes, HH, are also provided so that it can be turned by means of a pin key, or fork. This ring R carries a piece, T, to which is attached one end of the controlling spring. The zero of the instrument may be adjusted by turning the ring R in its seating. Every instrument of this class is fitted with a small detachable cover over the movement plug, by removing which any small regulation of the zero can be effected.

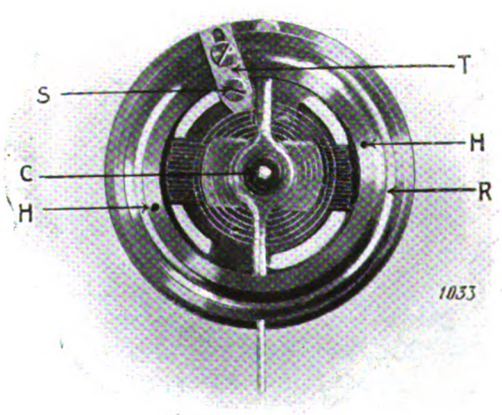

Fig. 2.—Movement Plug from the Front.

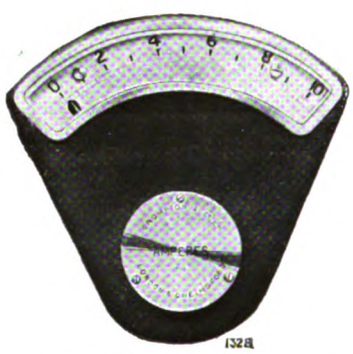

Fig. 3.—Sector Type Instrument.

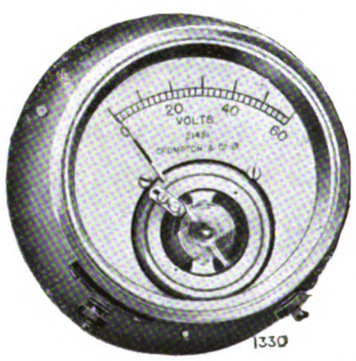

Fig. 4.—Flange Type Instrument.

Turning now to the instruments themselves, Fig. 3 shows those of the sector type, the scales being 5 in. long. They are intended principally for switchboard use, where there is not sufficient room for round instruments, or where a moving coil instrument at a somewhat lower price is required. They correspond to a 6 in. dial circular moving coil instrument, but occupy rather less space while having

Fig. 5.—Paralleling Voltmeter.

Digitized by Google

a longer scale. Ammeters whose capacity exceeds 20 amperes are provided with external shunts, while below 150 volts the voltmeter and resistances are self-contained.

A very useful class of instrument, ammeter or voltmeter, is shown in Fig. 4. The scales are $2\frac{3}{4}$ in. long and they can be supplied either with a flange or cross-bar for fixing purposes.

Fig. 6 shows an instrument mounted in a sector-shaped case, the scale on the outer face being either 8 in. or 12 in.

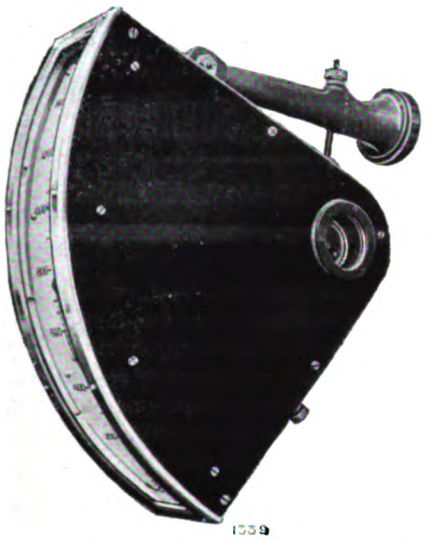

Fig. 6.—Sector Switchboard Instrument.

long. These instruments can be rigidly attached to a switchboard so that the scale is either horizontal or vertical.

Fig. 5 shows a type of instrument suitable for paralleling work. The instruments are arranged to stand the full voltage of the supply for which they are intended, and are fitted with a key so that the sensibility can be greatly increased when a balance of voltage is nearly obtained in the operation of paralleling.

Fig. 8 shows a leakage indicator for two wire circuits, which is arranged to give a continuous indication of

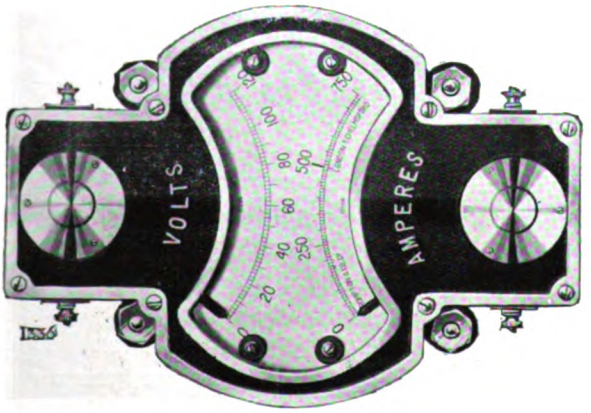

Fig. 7.—Combined Instrument for Motor Cars.

any inequality in the insulation resistance of the two mains, as required by the Board of Trade in certain installations. It also provides means of finding the actual insulation resistance of each main and the leakage current. The instrument is of the circular type and is used in connection with an external resistance. The resistance is coupled across the mains, and the indicating instrument is connected between the middle point of the resistance and earth. When coupled in this manner the indication of the pointer, and particularly any variation in the reading,

THE THOMSON ELECTRIC LAMP.

7/6

HALF SIZE.

shows the state of the insulation. The development of faults is usually preceded by unsteadiness in the readings, and the deflections of the pointer indicate by their direction in which of the mains the weakness lies. If the insulation resistance of both mains is equal, the deflection is nil, and the instrument gives no indication of the true insulation resistance. The insulation resistance of each main, however, can be separately measured, keys being provided on the instrument which allow it to be coupled in turn between each main and earth. Readings so obtained, when

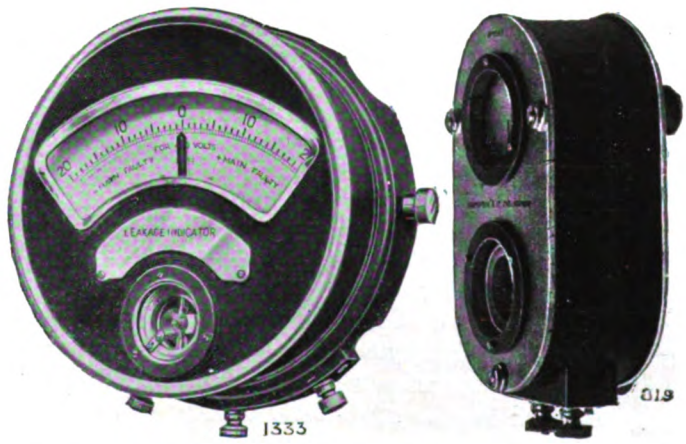

Fig. 8.—Leakage Indicator.

Fig. 9.—Instrument for verifying Ampere-Volt Indicators.

referred to a chart provided with the instrument, will give the insulation resistance. The leakage current can then be easily calculated, by dividing the voltage of the circuit by the sum of the insulation resistance of the positive and negative mains.

Fig. 7 shows an instrument which has been designed to meet the demand for a strong compact instrument for use on motor cars, launches, searchlights and other places where the available space is small. The cases are of stout cast aluminium, though cast iron can also be supplied.

An important point in connection with all electrical instruments is their correctness. The gauge shown in Fig. 9 has been designed to carry out zero and maximum reading tests. It is fitted with a moving coil movement, but has a single mark instead of a scale, and is so adjusted that the application of 0·075 volt at its terminals, or the passing of 0·015 ampere through it, deflects the pointer exactly to this mark. This instrument is so designed that it can be readily checked against a potentiometer or other standard, and is adjusted in a simple manner by turning the adjusting ring provided on the movement.

THE ELECTRICIAN INDUSTRIAL SUPPLEMENT
ISSUED MONTHLY with "THE ELECTRICIAN"
Telegraphic Address: "ELECTRICIAN NEWSPAPER LONDON" Telephone No. 640 HOLBORN.

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Copy for Text or Advertisement pages for next issue, publishing on **June 24th, 1910,** *should reach the above address by Tuesday,* **June 14th, 1910.**

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms ; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations ; to any firm of Merchants or Agents ; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings ; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

The Choice of a System. Anyone who is able to spend a few minutes in the consideration of THE ELECTRICIAN Annual Tables of Electricity Supply cannot help being struck with the varying systems which are at present used in this country. And he will doubtless also be struck by a feeling of mild wonderment as to why certain systems were chosen in certain particular cases. Why, for instance, two-phase high-tension current with sub-stations should have been selected as a fit and proper system to supply a small and congested area and why it was necessary to erect a single-phase station in a town inhabited mostly by power users. Such schemes are at best a living monument to the nearsightedness of those concerned, or, put another way, to an optimism which is scarcely likely to be justified.

In both of the more or less hypothetical cases mentioned above it would have been more economical and better engineering to instal continuous-current stations, at least, in the first instance. This has, it is true, often been done with success, but these stations are now faced with a problem which to a certain extent arises from the increasing use of metal filament lamps and the migration of the inhabitants of practically every city from the centre to the outskirts. The problem of how best to get over these difficulties is discussed by Mr. Wunder in a recent issue of the "Elektrotechnische Zeitschrift." He points out that in the case outlined above special stations would either have to be built for the supply of these districts or the present stations extended by the erection of single or three-phase generating plant. Taking 100,000 inhabitants as a basis for his calculations, the author finds it is considerably more economical to use polyphase than continuous current.

The cost of installation and current losses will in this case be about one-third less than with continuous current, while the saving in capital expenditure is also considerable. Mr. Wunder's article and results are a case of theory following after practice, and it is interesting to note that in this case at least, these two often opposing factors are in agreement. The excellent results obtained with this arrangement in many towns in this country, notably Manchester, fully bear out Mr. Wunder's theoretical investigations.

Coal Handling Problems. In the discussion on Mr. J. H. Rider's Paper read last year before the Institution of Electrical Engineers a variety of opinions were expressed on the relative advantages of waterside and "inland" stations. It is, of course, natural that every effort should be made to get the coal into the vicinity of the station as quickly as possible, but it is just as important, and should be just as natural, to ensure that the handling of coal within the station itself is effected as cheaply as possible. Present-day tendency is all towards economy, and by making certain that there is no waste of time or labour between wharf or cart, and bunkers, still more will be done towards a further reduction of working costs—a reduction which has been commenced by doing all that is humanly possible to prevent losses in the boilers and main steam pipes. Too often have we seen, and still, in fact, see, coal brought to a station in carts and then laboriously removed by hand to the bunkers instead of being mechanically handled far more quickly and in greater quantities than is possible by hand. It is true, that at many waterside or railside stations, especially the latter, arrangements are made for dealing mechanically with the fuel. Coal is tipped straight from the truck into special hoppers and fed into the boilers without being hand-touched. We feel that much more might be done, with advantage to all concerned, in this way at "inland" stations. The total annual cost, including fixed charges, of operating a small electrically-driven crane in a station consuming two or three thousand tons of coal per year should be easily less than the expense of handling by ordinary manual labour. The coal could be brought to the station in much larger units than would be possible under the old conditions and handled much more quickly. Power would be cheap and labour would be reduced to a minimum. Where the station is on the quayside some sort of telpher system can be conveniently employed. There is, of course, the financial side of the question to be considered, but even to those stations who are not able to spend a large amount of capital, the reduced working costs and thus the good return on the money paid out should specially appeal.

With coal in its commercial form a certain amount of waste is inevitable, but the less it is handled or moved from one receptacle to another the better. Each transfer from barge to cart, and cart to bunker, and bunker to boiler means a certain loss, and these should therefore be avoided as far as possible.

TABLE FAN WITH RIGID BASE.

"If it's fans, then go" "to the 'Sun' Co."

is an expression often heard in electrical circles, and the implied compliment is not unmerited either, for we hold one of the largest and most comprehensive stocks of fans to be seen anywhere.

By virtue of their sound workmanship and artistic appearance, "Sun" fans have acquired a reputation second to none.

If you appreciate quick delivery and unerring attention to your instructions, coupled with apparatus of high-class quality, send to-day for our Fan List, gratis and post free on request.

THE "SUN" ELECTRICAL Co., LTD.,
118-120, Charing Cross Road,
LONDON, W.C.

This oscillating Fan Base is an ingenious invention, which will transform an ordinary table fan into an oscillating one at trifling cost.

Small Hydro-Electric Plants.

We are often told that the inhabitants of this country are greatly handicapped by the absence of water power. Eyes are longingly cast on Sweden, Norway, Bavaria and other places where large falls are in evidence and where, therefore, it is possible to generate energy very cheaply. It may, however, be pointed out in reply to this argument that we are much luckier than other countries in possessing an abundant coal supply. There is practically no industrial area in this country where coal is neither cheap nor plentiful, and it is to be doubted whether, even if we had large waterfalls, it would be more economical to erect stations, in the out-of-the-way places where they exist, to supply industrial areas than to use the coal and generate the power more or less where it is wanted. In fact, one authority has pointed out that there are sources of water power in this country which could be utilised if there were necessity to do so, and the fact they are not points to the conclusion that we have better means at our command.

In making these remarks we wish them to act as a prelude to our calling attention to a use to which these small streams or waterfalls might be well applied. Much has been done in Germany and America in applying the electric drive to agricultural purposes. A small stream is harnessed, and a plant erected from which the farm machinery can be easily driven, while at the same time farm buildings can be supplied with a good light. In the INDUSTRIAL SUPPLEMENT for March we pointed out that the petrol electric set formed an excellent generating plant for this purpose, but where water power is available there is no doubt that it has even greater advantages as far as the farmer is concerned. There are certainly many places in this country where water power is already used, but it is employed inefficiently, and by no means the best is got out of the plant used. An interesting example of what may be done in this way is given in a recent issue of the "Electrical World." A farmer in Utica has erected a small hydro-electric plant on his farm which supplies the owner's premises with light, heat and power. The owner has gone into the matter thoroughly, and has expended rather more capital on the project than perhaps was actually necessary, but he has got in return a highly efficient plant and one which should supply him with power very cheaply. The generator plant has a capacity of 10 kw., and supplies direct current to the farm buildings at a pressure of 230 volts. Transmission is by means of a pole line, to which is fixed insulated wire. The plant is controlled from the house by means of a simple arrangement for ifting or closing each generating station. The switchboard, being at the house itself, it is also possible to regulate the voltage from the same point without going down to the station. It may appear that the output from this generator (10 kw.) is very small, but it would be quite possible so to arrange matters that the energy generated was used for power in the daytime and for lighting at night. By so using, with a small set and the expenditure of very little capital, all the benefits of the electric drive could easily be obtained. We should like to see this example more generally followed in this country. At the present time the cry of "Back to the Land" is ever ringing in our ears, but if we are so to return, full advantage might be taken of the present resources of civilisation in getting out of the soil every possible yield.

Hydro-Electric Pumping Plant for a Gold Mine in Brazil.

IN considering the question of gold mining in Brazil it is well to remember that waterfalls are plentiful and that power is therefore very cheap. It therefore, happens that many mines are worked at a profit which otherwise would have to be abandoned. The plant described below was supplied by the Sandycroft Foundry Co. to such a mine, and is employed for pumping water from the lower levels of the mine. Fig. 1 shows a section of the mine and the relative position of the various parts of the plant. The power water is brought along the old rego A and enters the pipe line at B. This pipe line carries the water to the power station at C, which is situated just above the river. The cables pass from the power station along the shallow adit D, down the shaft E to the pump situated at F. The water discharged by the pump passes through pipes up shaft E, and along the deep adit G, where it is discharged into the river further down, and at a lower level than the power station. The effective height of fall for the power water is 200 ft. and the amount of water available about 282 cubic ft. per minute. The pipe line is of steel of 16 in. inside diameter.

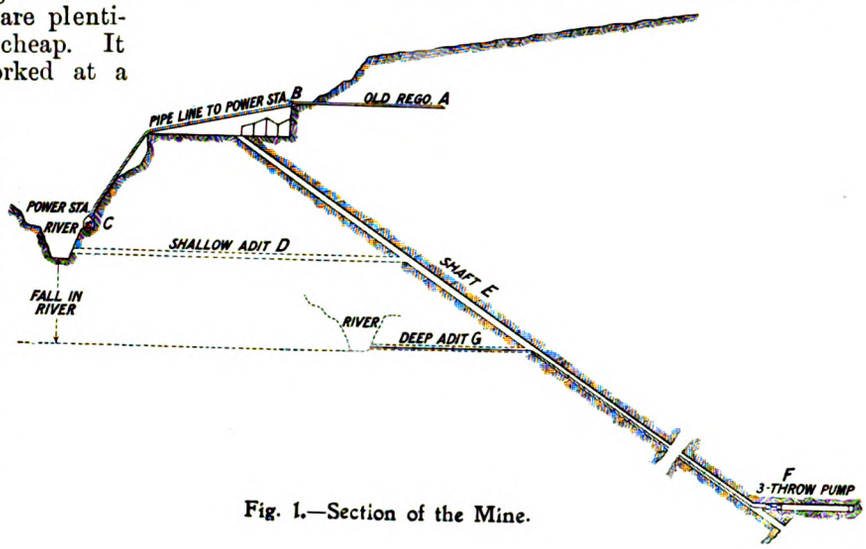

Fig. 1.—Section of the Mine.

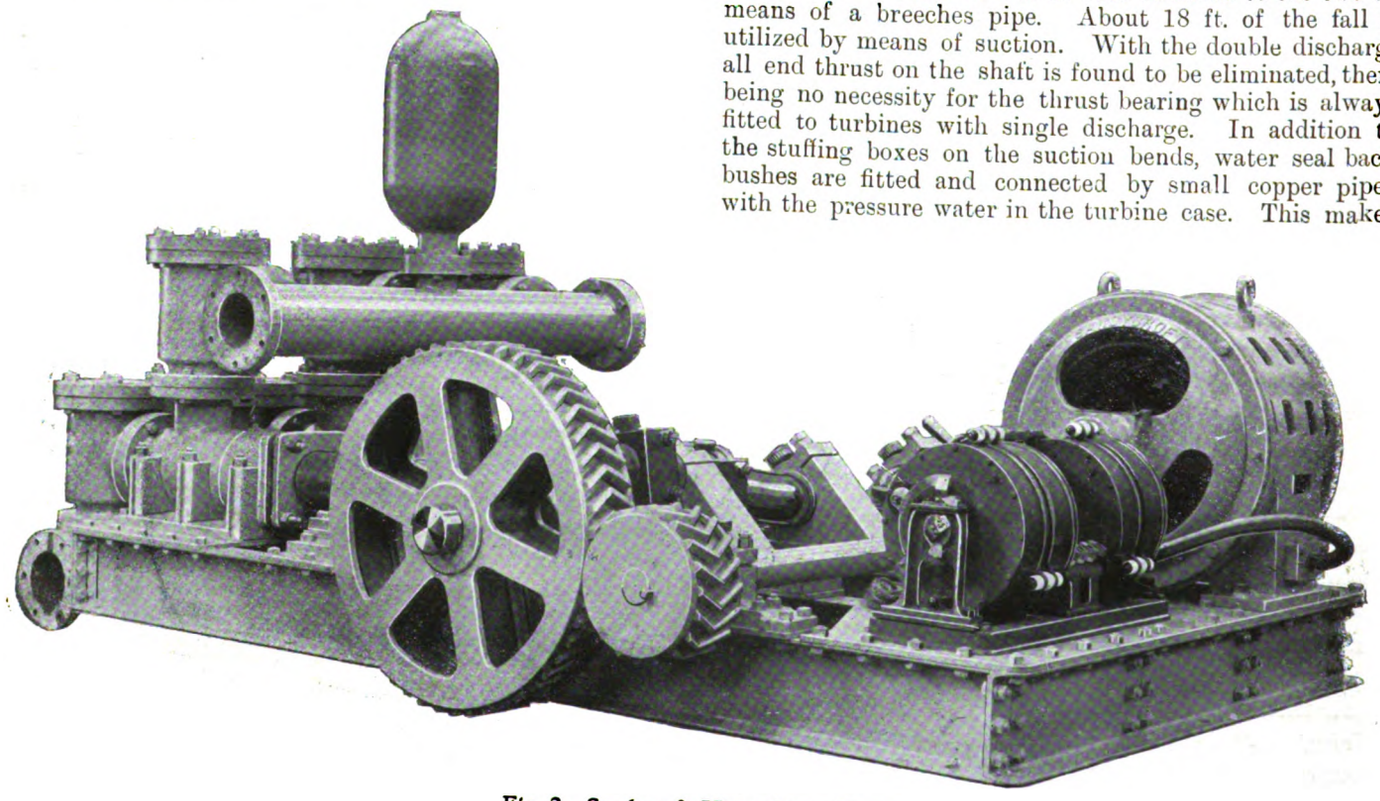

Fig. 2.—Sandycroft Motor-driven Pump.

The arrangement of the power station, which contains turbine, generator, exciter, switchboard, &c., is shown in Fig. 3. The turbine is of the "Gilkes" inward flow type, known as the double vortex. It is designed to develop 80 B.H.P. with an effective fall of 200 ft. using 282 cubic ft. of water per minute and, making 1,000 revs. per min. The outside casing is of spiral form in order that the water may have a uniform velocity inside the case. The water is directed on to the wheel by means of short movable guides of the "Francis" type, which ensure, it is claimed, a very high efficiency at all loads These guides are made of gunmetal and are actuated by means of a gunmetal ring, which, in turn, is operated by the cranks. These latter receive motion from the governor cylinder. The revolving wheel is of brass and has a dividing plate, so that half the water is discharged on each side and passes out through the suction bends. These bends are connected to a draft tube common to the two by means of a breeches pipe. About 18 ft. of the fall is utilized by means of suction. With the double discharge all end thrust on the shaft is found to be eliminated, there being no necessity for the thrust bearing which is always fitted to turbines with single discharge. In addition to the stuffing boxes on the suction bends, water seal back bushes are fitted and connected by small copper pipes with the pressure water in the turbine case. This makes it impossible for air to be drawn into the suction tubes. The turbine shaft is supported in a ring-oiled bearing, a flexible coupling being used for coupling to the dynamo. Speed regulation is attained by means of a hydraulic governor. This governor is of the hydraulic relay compensating type, which, while allowing the turbine gate to be moved over its full range from shut to open in as small a period of time as four seconds, at the same time, it is

Digitized by Google

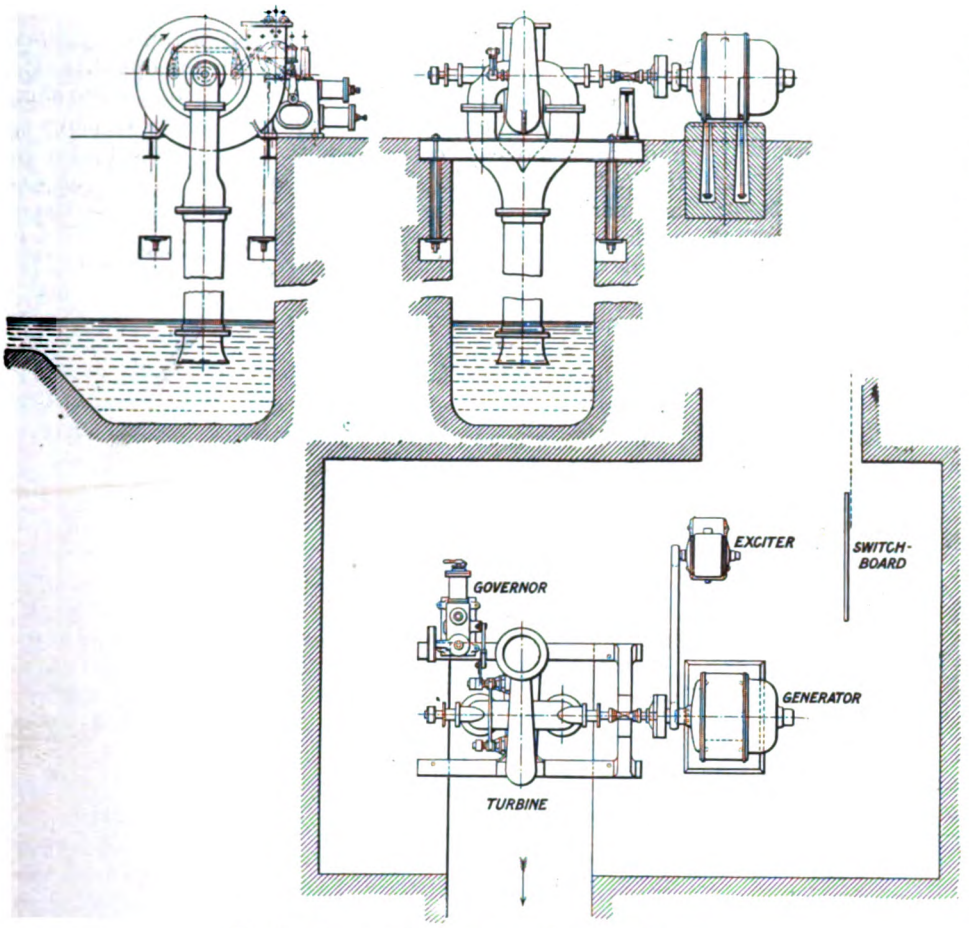

Fig. 3.—General Arrangement of Power Station.

claimed, entirely prevents hunting even when running on the lightest loads. The rotating parts of the governor are all automatically lubricated, which enables the plant to be left running for very considerable periods of time without any attention.

The generator is of the three-phase revolving-field type capable of giving out 68 k.v.a. at 550 volts, 50 cycles, when running at a speed of 1,000 revs. per min. The armature core is made up of insulated plates 0·02 in. thick, having open slots, and is wound with former wound coils of the barrel type covered with waterproof insulation. These are held firmly in the slots by strips of hard wood. The plates for the field poles are $\frac{1}{16}$ in. thick, and are riveted together and fixed to a steel hub by means of keys. The arc of the pole surface is of suitable radius to obtain a sine curve. The field is energised from a 100-volt continuous-current dynamo, which also supplies current for lighting purposes.

The switchboard is made up of one alternator and one exciter panel, the main switch being of the oil-break type with trip coils on two phases. The power is transmitted along the shallow adit to a junction box near the shaft by three bare copper conductors of 19/15 S.W.G. which are held by leather suspenders hanging from porcelain insulators; from the junction box three-core insulated cable is taken to the motor panel at the shaft bottom, it being necessary to insulate this cable as the shaft is damp. The motor panel is of the enclosed type and is fitted with ammeter, voltmeter and oil-break triple-pole switch with trip coils on two phases. The pump is driven by a "Sandycroft-Hunt" 50 B.H.P. "cascade" motor, running at 490 revs. per min. this type of machine being used as it is without slip-rings, rubbing contacts, brushgear, &c., thus eliminating the chief source of trouble found with motors working in mines. The only attention required by the machine is that necessary to keep the bearings supplied with oil. The motor is capable of starting up the pump against the full head of water and can be started up gradually by a starting switch of the enclosed liquid type, as shown in the illustration. Full load starting torque is obtained with full load current. The pump, which is shown in Fig. 2, is of the horizontal three-throw ram type, having single-acting rams of 7 in. diameter and 12 in. stroke running at 53 strokes per minute, and delivering 250 gallons of water per minute to a vertical height of 450 ft.

The bed frame is built up of steel joists and channels, thus permitting it to be easily sectionalised for transport and allowing of it passing through confined places to its working position in the mine. The first reduction gearing is machine cut, the motor pinion being of forged steel and the wheel of cast iron. The second reduction gearing, as will be seen from the photograph of the pump, is double helical machine moulded. Bent cranks are used, and the pump valves are of the mitre type. These pumps have an efficiency of between 75 and 80 per cent. at 500 ft. head. They are said to be very reliable for mining work, being specially designed for that purpose. A large number have been built by the Sandycroft Foundry Co. for mines in this country and in other parts of the world.

Siemens Tramway Meters.

ATTEMPTS were made in the early days of tramway development to utilise ordinary meters for the purpose of recording the energy consumption of tramcars under working conditions. These attempts proving unsuccessful, Messrs. Siemens Bros. Dynamo Works, who were among the pioneers of tramway development, applied special attention to the production of a reliable tramcar meter, with the result that they have succeeded in

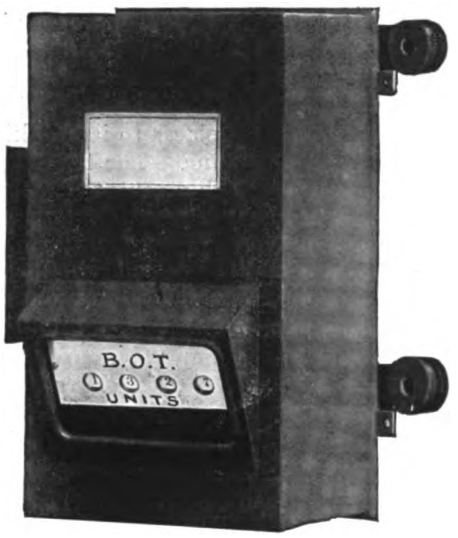

Fig. 1.—Siemens G.K.B. Meter.

putting on the market a meter which, after extensive trials under working conditions, has proved itself to be fully capable of meeting all the requirements of the situation. We illustrate, in Fig. 1, a Siemens type G.K.B. meter, and in Fig. 2 is shown the same meter with the cover removed.

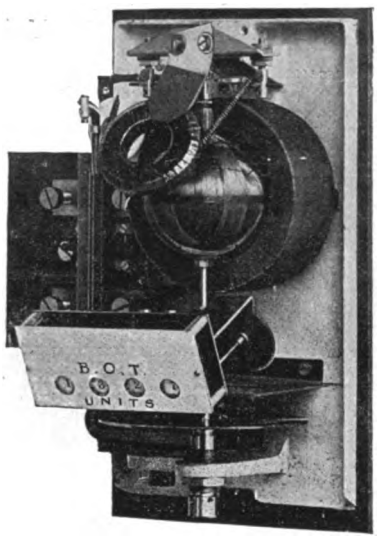

Fig. 2.—G.K.B. Meter with Cover Removed.

One of the chief difficulties was found to be in the bottom bearing. This, in the Siemens meter, has been overcome in a very ingenious manner. As may be seen from Fig. 3, the bottom pivot is not turned solid on the ends of the armature spindle, but the latter itself is drilled to form a cylinder in which is a steel piston abutting against a spring control; the bottom end of this piston is cone shaped. The bottom pivot is of highly polished and hardened steel and is held in position at the end of the piston by friction. The jewel is also spring supported from the opposite side, so that any vibration which would tend to produce chattering, causes the jewel and the pivot point to move up and down as one piece. All vibration is taken up by the top and bottom springs, thus eliminating all possibility of hammering of the jewel. Other details, as the outcome of extensive practical experience, have also been embodied in the design of the Siemens tramway meter. The li e of the meter can be safely taken as at least five years, the maintenance cost are low, and provision is made for the easy renewal of all wearing parts.

A large number of these meters are in active service in England and on the Continent, and in instances where figures are obtainable, it is seen that large economies in

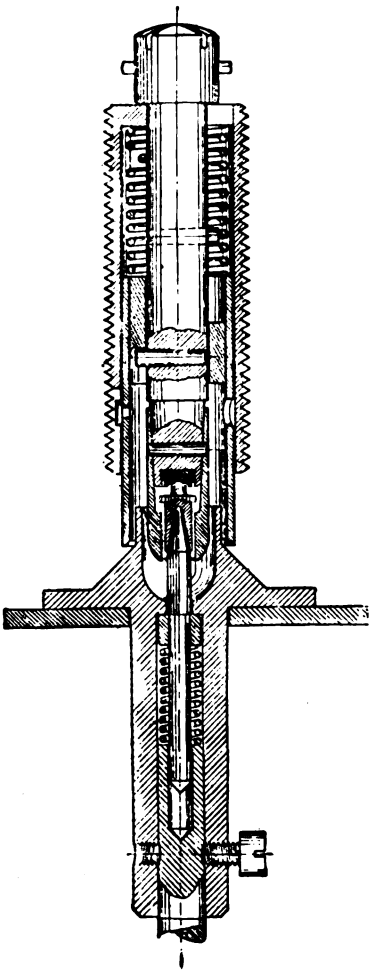

Fig. 3.—Bottom Pivot of G.K.B. Meter.

current have been effected, varying from 4 to 20 per cent., the average being in the neighbourhood of 10 per cent. Since a car meter has to deal with current to the value of approximately £200 per annum on an average, a saving of 10 per cent., namely £20, on that amount would repay the cost of the meter several times over in a single year.

The economies effected by the use of meters on tramcars afford an interesting sidelight on one phase of human nature. Without the meter the driver tends towards carelessness, towards rapid starting and still more rapid braking, all of which are operations harmful to the equipment and unpleasant to the passengers. When a meter is fitted, however, the motorman feels that he is constantly under supervision, even though it is only by an instrument, and orders his doings accordingly; with the result that the equipment is operated in a normal fashion and the passengers are no longer jerked from their seats.

Sulzer High-Lift . . Centrifugal Pumps.

AMONG the firms who have exerted a great deal of influence on the development of the rotary pump may be justly placed Messrs. Sulzer Bros., of Winterthur. The principle on which this type of pump works is, of course, well known, the liquid being put in motion by a more or less quickly rotating impeller and then raised by centrifugal force. The shape given to the impeller, as well as that of the casing surrounding it, varies between wide limits, the ultimate design depending upon the work required from the pump.

In the high-lift centrifugal pumps made by Messrs. Sulzer Bros. the guide wheel surrounds the impeller and serves to divert the water discharged from the impeller, reduce its velocity and convert part of the latter into pressure, whereby the lift and efficiency of the pump are increased.

Great lifts are obtained by the arrangement of several impellers in series on the same shaft with their guide wheels surrounding them. In the first impeller and guide wheel the fluid is brought to a pressure or lift corresponding to the number of revolutions, from whence it passes into the second impeller and leaves the same with double the pressure; from the second wheel it passes in the same manner through a third, fourth or *n*th impeller and guide wheel, so that the final pressure or total lift corresponds to two, three, four or *n* fold of the lift of the single impeller.

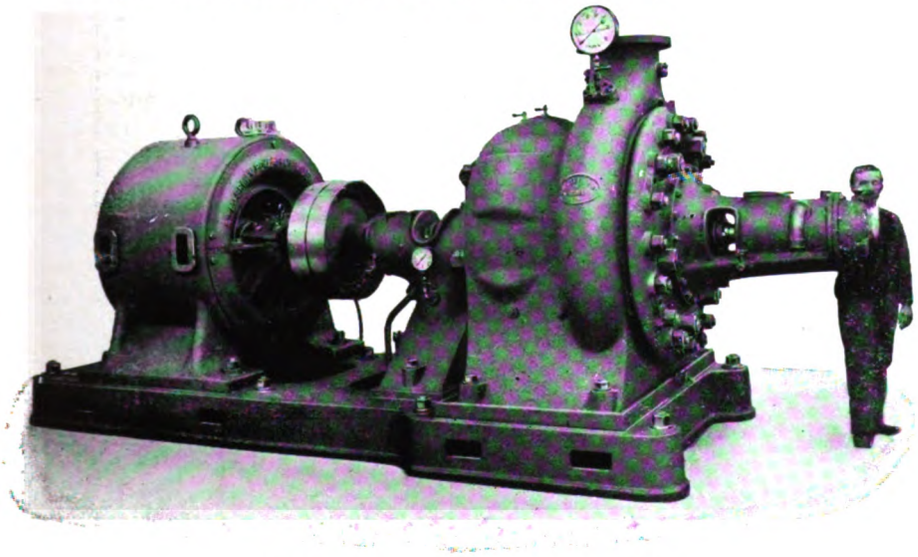

Fig. 1.—Sulzer High-Lift Centrifugal Pump.

The number of impellers arranged in one casing is further dependent on various constructive questions, especially on the quality of bearings.

In the six-stage high-lift centrifugal pump the casing consists of six annular pressure chambers, the last of which is provided with the delivery nozzle. The suction nozzle is bolted on the left side of the casing, while the other side of the latter is closed by a cover.

The pump shaft is supported on the one side in the suction nozzle and on the other in a bearing mounted on the cover. This last-named bearing, which is patented by Messrs. Sulzer Bros., is arranged in such a manner that water from the last pressure chamber leaks through around the shaft into the separate chambers of the bearing and on its way to the outlet cools the oil chamber as well as the bearing itself.

The six impellers are keyed on the shaft in pairs in such a way as nearly to eliminate the side thrust. Two impellers are surrounded by one double guide wheel, which contains the spirally shaped guide channels and the overflow openings. The circular section of the suction nozzle changes to an annular one before the first impeller, to give the fluid a uniform inlet into the first impeller. Between two pairs of impellers an intermediate piece is contained, which is provided with the overflow channels, while the suction chamber for the sixth impeller is arranged in the cover.

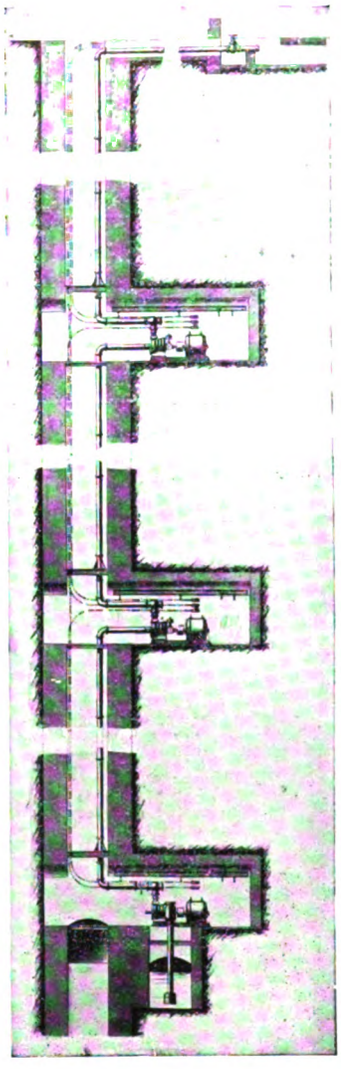

Fig. 2.—Section of Horcajo Silver Mine, showing Pumping Arrangement.

The efficiency of Sulzer pumps is quite satisfactorily high. For instance, a plant at Horcajo, in Spain, where 235 H.P. pumps are installed, an efficiency of 79·5 per cent. was obtained at a speed of 1,320 revs. per min. and a delivery of about 6 cubic metres per min. In another case a Sulzer sinking pump delivering 16 cubic metres per min. at a manometric head of 45 metres when running at a speed of 1,025 revs. per min. gave an efficiency between 83 and 84 per cent. in accordance with the conditions of working. Such a type of pump is naturally very suitable for direct coupling to the electric motors and, as may be seen from our illustrations, this combination is at present receiving a wide application. Fig. 1 shows such a set, the

Digitized by Google

motor being of the alternating-current type and fixed on the same bed-plate as the pump. This illustration also gives a good general idea of the pump design, showing its compactness and other desirable features.

In considering the question of electrically-driven pumps, the field of application is doubtless the section to which most attention should be drawn. It will suffice to say in this connection that Sulzer pumps are now being employed for a variety of uses—uses which differ so widely as irrigation and fire extinguishing, and are found to work satisfactorily under all sorts of conditions. For instance, Sulzer pumps are actively engaged in connection with the water supply of Milan. At first three pumping stations were built for this purpose, which were supplied with alternating current from a central electric station and in which the pumps were direct coupled to motors. A fourth pumping station will be erected in the near future, in which the pumps will be driven by belt from gas engines, rather a retrograde movement on the part of the municipal authorities. Pipe wells (till now 45) are connected to many places in the middle of the town, from which the water is led to suction air chests, where it is freed of its air and from whence it is drawn directly by the pumps, the suction height reaching 8·2 metres without trouble. The largest pumping station (Fig. 3) is in Loreto. The four direct-coupled pumps draw from a common air chest. All pumps work independently of each other and deliver into a common delivery pipe. Each pump delivers 3·6 cubic metres per minute to a head of 57 metres at 820 revs. per min. The second station is located in Via Parini and contains two equally large pumps directly coupled with electric motors. The third station with only one pump is in the same street. The pump is mounted over the well, and draws directly from it. The fourth station, now in course of erection, will contain three pumps, each of which will deliver 6 cubic metres per minute to a head of 52 metres when running at 925 revs. per min.

In connection with the application of electrically-driven pumps to mine draining, it is interesting to note that one of the first plants of this kind was built by Messrs. Sulzer Bros. in 1898 for the Horcajo silver mine in Spain (Fig. 2). The plant, which since its erection has practically run uninterruptedly, delivers at an average rate of 4·8 cubic metres per minute. As seen in Fig. 2, the plant works with several pumps at various levels with a total head of 480 metres. The arrangement is such that the lowest pump draws the water from the sump and delivers it to the next pump, which latter again forces it to the following. The upper pump receives the water under pressure, so that its filling is always assured and no air can enter. The pumps all work exactly in accordance, as they have the same speed, and the same water passes through them. They are four-stage pumps with impellers of 500 mm. diameter, and deliver each 4·8 cubic metres per minute to a 130-metre head when running at 850 revs. per min. The central power station contains six Sulzer cross-compound steam engines, which at 115 revs. per min. each develops 525 I.H.P. The working steam pressure is 8 atmospheres. The six-pole alternating-current pump motors work at a terminal pressure of 1,000 volts. In consideration of greater depths to be overcome and an increased water flow, a new drainage plant was erected by Messrs. Sulzer Bros. in Winterthur for this mine in the latter part of 1903. The pumps of the new plant deliver each 6 cubic metres to a height of 130 metres at 1,310 revs. per min.

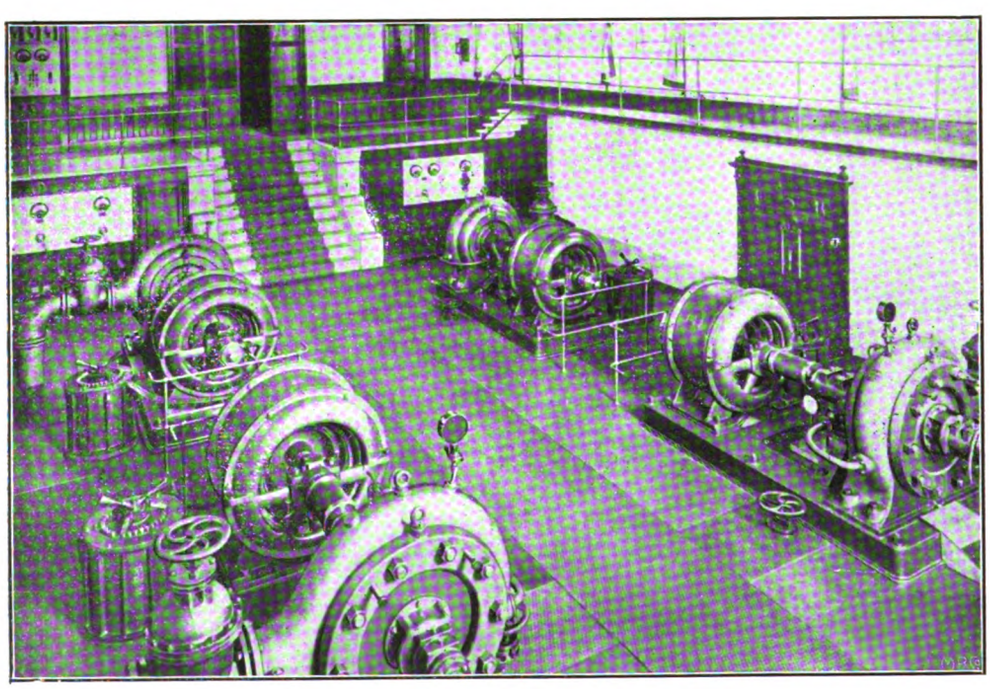

Fig. 3.—Loreto Pumping Station at Milan.

Fig. 4.—Sulzer Vertical Pump.

A more modern arrangement in which the entire head is overcome in a single lift is installed in the Victor mine at Rauxel, in Westphalia. Two four-stage high-lift centrifugal pumps are coupled in series, and deliver 7 cubic metres a minute to a head of 524 metres when running at 1,040 revs. per min. The horse-power required by each set is 570. The combined efficiency of the steam generating and pumping plant is 58 per cent.

Another important mine drainage plant is that installed by Messrs. Sulzer at Ems. Current is supplied from a central power station at a pressure of 8,000 volts, and Sulzer

Digitized by Google

pumps were erected to overcome the large quantities of water present.

The pump chamber in the ninth level is capable of taking four pumping sets, three of which are already at work. They are six-stage 200 H.P. high-lift centrifugal pumps, each of which when running at 1,455 revs. per min. will deliver 2·52 cubic metres per minute to a head of 255 metres. Each pump is coupled direct to an asynchronous motor of 225 B.H.P. normal output at the above stated speed, taking current at 1,000 volts and 50 cycles. The motors have no slip-rings, and are provided with water-cooled ring bearings. The pumps draw direct from the water drift of the mine level by means of a common suction pipe. Later on the water will be fed under pressure from the sixteenth level by a second suction pipe. The delivery pipe is common to all pumps, and consists of a large collecting pipe with branches which leads to the surface. The great length of the piping was dependent on the location of the already existing pump chamber. Each pump works independently of the others, and according to the fluctuation in the flow of water and to season, one, two or three pumps are in operation at a time. The drainage of the not flooded ninth level downwards to the sixteenth level was accomplished by Sulzer sinking pumps. To treat with smaller quantities of water in the side or trial drift, which water must be removed without delay, the Sulzer drift pump is employed. The pump is direct coupled with an electric motor and mounted together with it on a small carriage. The current is transmitted through a flexible cable and plug contact.

The latest application of the high-lift centrifugal pumps consists in the construction of pumps with vertical shafts, which are usually coupled to alternating-current motors. These sets are employed as sinking pumps when sinking shafts. They require very little space, are self-contained and easily accessible. They can work while suspended freely, without requiring any excavations or supports in the shaft. Fig. 4 shows one of these sinking pumps, which is operated by means of a gate valve hand wheel and ammeter. The pump is of the four-stage type and capable of delivering 3 cubic metres per minute to a head of 200 metres, when running at 1,450 revs. per min., and then requires 185 B.H.P.

De Dion Bouton Engines.

A FIRM of motor car makers who, profiting by the experience gained in the construction of light engines for cars, are now manufacturing engines for the use in the larger sphere of industrial operations, agriculture and generally for all uses for which the engines formerly offered to the public were unsuitable on account of their weight, size and complication, are the De Dion Bouton (Ltd.).

Fig. 1 shows such a set of the 6 H.P. type. These sets are mounted on cast-iron stands, with pulleys revolving at 300 revs. per min., which is a suitable speed for working, by means of a belt, any kind of machinery, such as threshing machines, root-cutters, cream separators, churns, saws, planing machines, wringers, pumps of all kinds, &c.

The sets consist of a De Dion Bouton engine driving through a pinion fixed to the end of the engine shaft, a toothed wheel fast on the pulley shaft. The whole is mounted on a cast-iron stand. The carburettor is fixed on to the engine, and the timing gear is enclosed in a gear case. The battery is supplied in a special box with the sets, the coil being placed in the interior of the cast-iron stand. The single cylinder engines are cooled by thermosyphon circulation. For combinations with two cylinder engines the water circulation is effected by means of a pump.

The single cylinder engines are lubricated by splash feed. A drip feed lubricator can be fitted to these motors. This apparatus ensures the lubrication without stopping the motor. The two cylinder engines are fitted with an oil-pump, and the lubrication is automatic.

An automatic governor can be fitted to 6, 8, 10 and 12 H.P. combinations. It is not indispensable, but in most cases it facilitates the running of the engine. It is a centrifugal governor driven by pinion, and acts on the exhaust or the carburettor of the motor so as to maintain a constant speed. The adjustment for a given speed is very simple. It is only necessary to alter the tension of a spring by means of a nut.

Examples of the petrol-electric generating sets made by this firm are shown in Figs. 1 and 2. These sets consist of a vertical high-speed De Dion Bouton engine direct coupled to a dynamo. Constant voltage under varying load is maintained by an electrically-operated governor acting on a throttle on the gas inlet. The engines on these direct-coupled sets are exactly the same as those in use on De Dion Bouton cars, industrial vehicles and motor boats. The dynamos employed are bi- and four-polar with drum-wound armatures and are self-excited. The fields are self-excited, and the field connections are made direct to the brushes. Ball bearings are fitted, and these are easily accessible. The brushes are fixed in position and require no adjustment; they should be left in the same position as set until the brushes are completely worn out. The governing device, fitted on these sets, consists of a solenoid acting on a conical plunger, which is free to move in a tube. In order to make full use of the magnetic field and thereby to diminish the amount of current passing through the soleniod, this is completely encased in a hollow cylinder, which completes the magnetic circuit. This also has the advantage

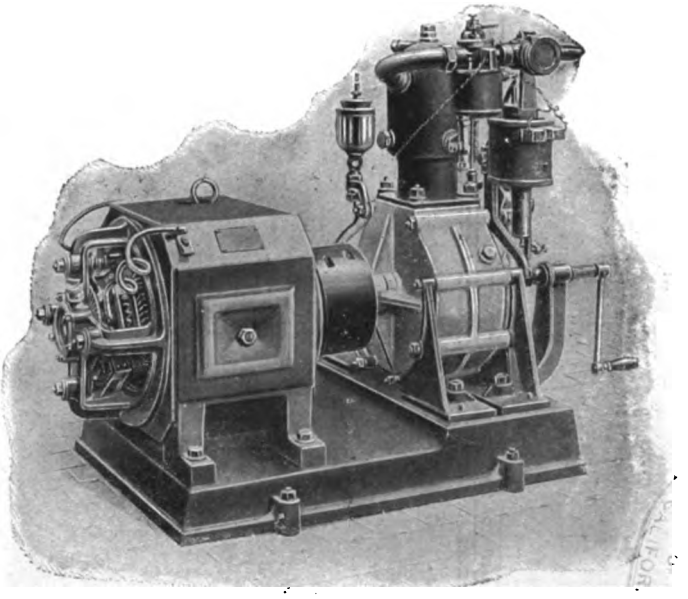

Fig. 1.—Single-Cylinder Generating Set.

Digitized by Google

of rendering the apparatus insensible to any stray external magnetic field. The upper end of the core of the solenoid is attached by a chain to a pulley keyed on to the spindle of a throttle valve in the passage of the explosive mixture coming from the carburettor. A spiral spring is attached by one end to the spindle and by the other to a cover, the position of which it is possible to alter, consequently the tension of the spring and, therefore, the sensitiveness of the apparatus can be varied at will. It also follows that the apparatus may be still further adjusted by altering the position of the core with respect to the solenoid, this being effected by means of a series of holes drilled on the internal face of the pulley, into which the attaching pin may be inserted. The amount of energy consumed by this arrangement is about 5 watts. These sets are also made for portable purposes, and in this connection we may call attention to a patent hydraulic suspension for petrol electric generating sets which has been designed by De Dion Bouton. This system utilises the water tank as the foundation of the set. The dynamo is directly coupled to the motor, and the set is bolted to a base which floats on the water. The water ensures the insulation of vibration, and also acts as the means of cooling the exhaust gases. The dynamo set can be supplied assembled with the float, so that upon the tank being bolted down and the petrol pipe connected it is ready for immediate service. The motor and the dynamo are bolted to a float which is supported in the tank by the cooling water. Spring connections, one at each corner, keep the float central with the tank. The pump draws up the water by the pipe, circulates it round the engine, and then expels it by the pipe. Excessive heat is prevented by varying the capacity of the tank in proportion to the size of the motor, and the sides of the tank acting as radiators. Another advantage of this system is its silencing effect. To attain this the exhaust pipe is passed through the water tank; the cooling of the gases causes their expulsion at low pressure, and the noise of their final escape to the atmosphere is almost suppressed. The system is, it is claimed, a real improvement to the installation, whilst it adds nothing to its cost, as a water tank is necessary in any case, and it saves the expense of a concrete or similar foundation.

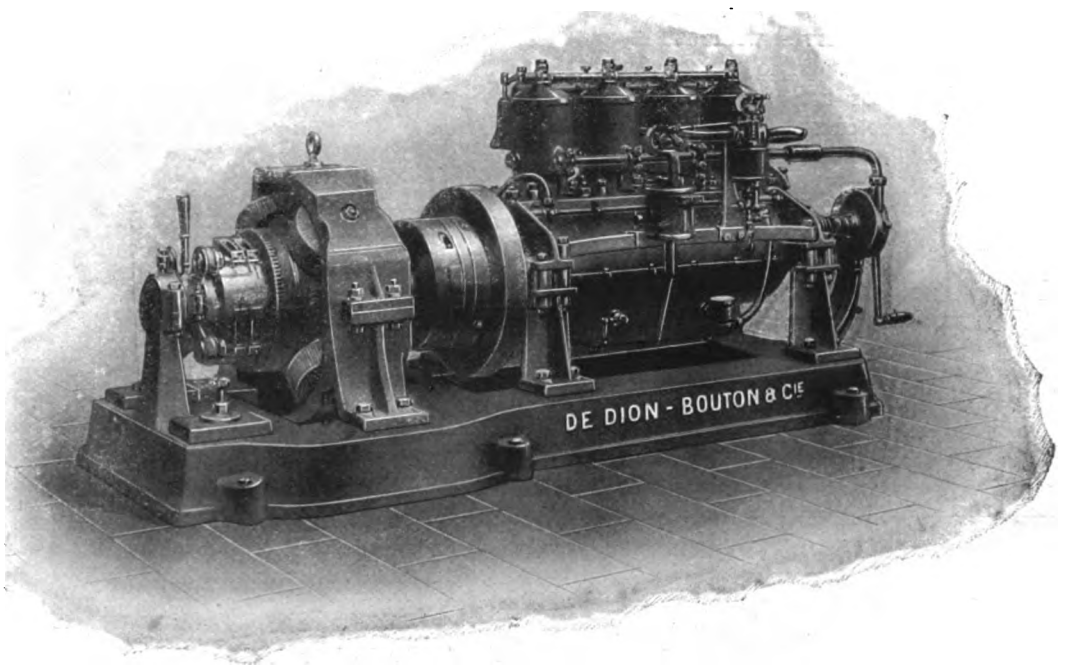

Fig. 2.—Two-Cylinder Generator Set.

The "Drum" Pump.

AS is well known, pumps, like many other things, may be divided into two main classes, centrifugal and piston. There are a certain number of pumps, however, which combine the features of both these classes. Among these may be placed the "Drum" pump manufactured by the Drum Engineering Co., of Bradford. It is claimed for this pump that it has the capacity of the centrifugal pump with the power of the ram—a very useful combination.

The pump consists essentially of a revolving piston that sweeps out the cylinder every revolution. The revolving piston dips into a revolving valve or cylindrical drum, the openings in which are so arranged that the piston passes through without appreciable slip, back pressure or undue friction. When the revolving piston moves round from the revolving valve a vacuum is formed, into which the water flows and is then forced in the front face of the piston.

The "Drum" rotary piston pump differs entirely from the ordinary rotary pump; the latter, like the direct-acting piston pump, is more or less intermittent in its action, and breaks up the flow of the fluid; the "Drum," on the contrary, passes the water through in one continuous flow without interruption, and utilises the power in the momentum of the moving column; thus the great advantage of centrifugal action is obtained without the cost of additional power. Another great difference between the "Drum" and the ordinary rotary pump is that the latter has usually two revolving working pistons, one of which is driven through the gear wheels. The "Drum" having only one rotary working piston, the friction and strain on the gear wheels and bearings of driving a second revolving piston are avoided.

The "Drum" pump is found particularly adaptable for use by contractors, dyers, brewers, paper makers, sugar refiners, soap and linoleum manufacturers, and for drainage works, docks, on board ships, and for pumping semi-fluids, chemicals, or for any purpose where large volumes are to be dealt with quickly and economically.

There are a number of different sizes of "Drum" pump, varying in capacity from 650 to 18,000 gallons per hour. They are specially adapted for direct-coupling to motors and an interesting arrangement has recently been supplied for drawing water from a river in China that is subject to great variations in level.

The pump and motor were placed in a small power house, mounted on a platform that could be raised and lowered on rails on an inclined plane on the bank of the river, so that the pump could always be placed within easy reach of the water without any risk of the motor being flooded.

M.A.N. "Double Drive" Cranes.

NOWADAYS an increase in the hoisting speed of cranes has become a necessity from an economical point of view. In many works, especially in foundries and fitting shops, disadvantages have, however, arisen on the adoption of high speeds owing to the frequent necessity of accurately placing the load, which procedure is, of course, thus rendered much more difficult than with cranes working at low speeds.

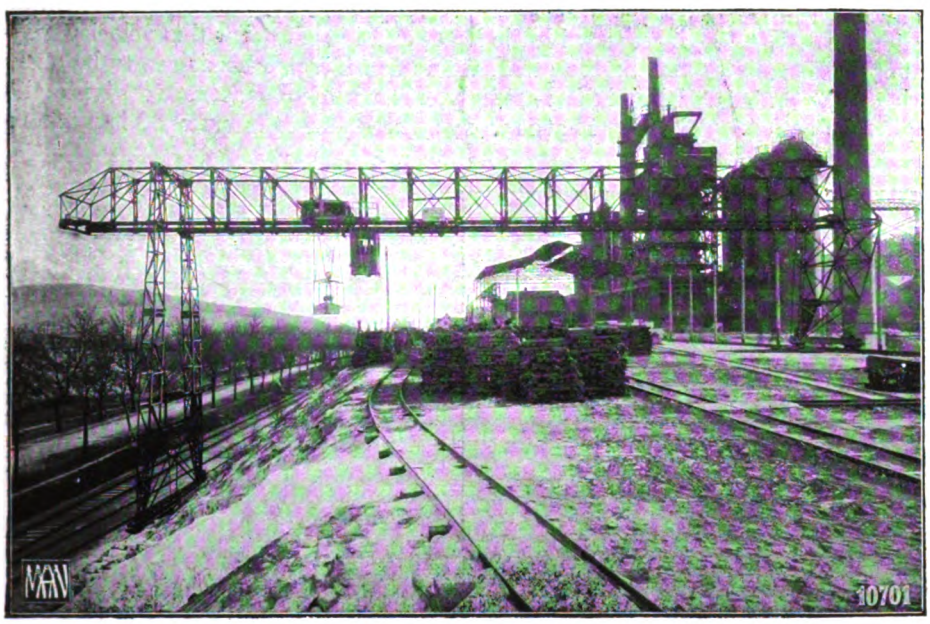

Fig. 1.—Crane for Transporting Pig Iron.

As the controllers in use render it possible to govern the speeds only within comparatively small limits, the want of an apparatus was badly felt, which—in the case also of rapid-hoisting cranes—would allow of quite a slow movement of the load in the simplest manner, without complicated speed-changing gear. The new "double drive" of the Maschinenfabrik Augsburg-Nürnberg A.G. not only, it is claimed, satisfies this want in a perfect manner, but also offers further advantages of considerable importance.

With the double drive, two electric motors work either alternately or simultaneously upon a peculiar but extremely simple driving gear, and in this way the various main speeds are obtained. Alterations in the speed are effected solely by means of the controllers—*i.e.*, without putting in action any mechanical apparatus, and this, it is argued, obviates *a priori* all errors. The main speeds obtained in this way can be graduated further by means of the regulation stages permitted by the controllers, so that a very far-reaching and extremely sensitive adjustment of the speed is ensured.

The following examples show further advantages of the "double drive." In foundries the patterns can be lifted quite slowly out of the moulds and can be transported as quickly as required. In steel works the heavy ladles can, on the one hand, be slowly moved by cranes fitted with the "double drive," and, on the other hand, the comparatively light ingot moulds and such like can be quickly shifted. Such lifting apparatus are of just as much importance also for workshops and fitting shops, where not only precise but expeditious working is required. The "double drive" is likewise advantageous for tower cranes owing to their great height.

The auxiliary hoisting gear used so much up to now for high speed for small loads becomes superfluous, and conse-

SIMPLE. CHEAP. ACCURATE.

quently the troublesome delay—resultant upon the presence of a second hook, which must always be previously moved out of the reach of the load—is also done away with. The general arrangement of the crab with "double drive" is simpler and more comprehensive on account of the decreased number of working parts, and the length of the crab is shorter, which means an increase in the sphere of action.

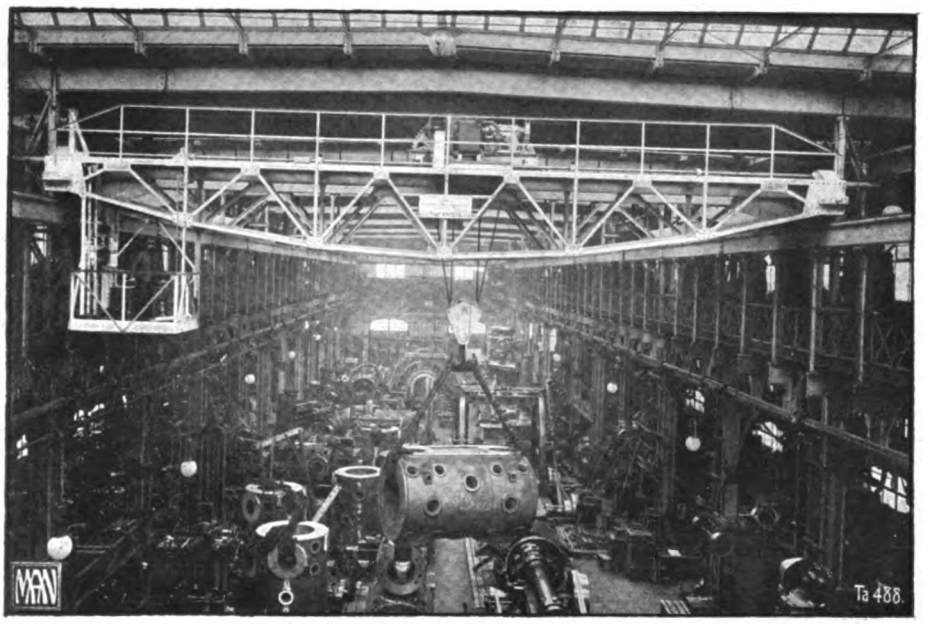

Fig. 3.—40-ton Overhead Travelling Crane with M.A.N. Double Drive.

Disadvantages and unreliability in working caused by mechanical or electrical couplings, &c., are, it is claimed, out of question with this arrangement. As two motors and controllers are available, safety in working is always ensured, for by the comparatively small extra cost of the "double drive" a stand-by is procured at the same time.

For driving the hoist of a 110-ton crab two motors of 68 B.H.P. each were used. They worked separately or simultaneously on worm gears. The centre lines of the worm wheels coincide with those of the planet gears, which drive the rope drum by means of toothed wheels (with smaller hoists one planet gear is available). The main stages of the speeds, which are varied further by means of the controller, are, for a maximum load of 110 tons, 6½ ft. per minute; a medium load of 25 tons, 26¼ ft. per minute; and for an empty hook, 46 ft. per minute. The alterations in the speed are effected solely by means of the controllers—*i.e.*, without putting in action any mechanical apparatus.

High-Lift Turbo-Pumps.

THE increasing use of the motor almost makes some type of rotary pump necessary if the full advantage of high speed is to be obtained. It is, therefore, not surprising to find the rotary pump more and more employed for a variety of uses. Among the firms who have taken up this class of work may be mentioned Messrs. Hayward Tyler & Co., whose particular brand of rotary pump we illustrate and describe in this article.

The mode of operation of this pump rests upon the following principle: A particle of water near the axis, entering the revolving wheel or "runner," is seized by its vanes, and thus compelled to take part in the rotation. Under the influence of the centrifugal force, it moves further and further from the axis until it is at last ejected near the circumference of the wheel, with an energy corresponding to a certain head. The greater the speed of revolution the greater is this energy. It is obvious that, in the case of a simple wheel, the velocity of the water discharged must increase with the head, and in order that this velocity may not be too great, where considerable heads are to be dealt with, it is necessary, for practical reasons, to divide the head. That is to say, the liquid to be pumped is made to

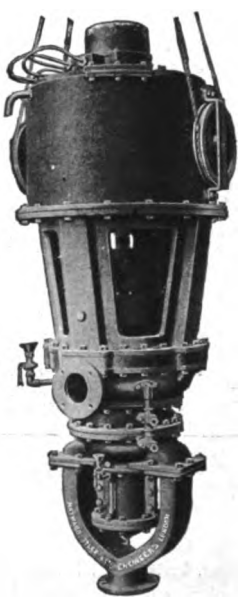

Fig. 1.—Hayward-Tyler Turbine Pump.

pass through several runners in succession, each one of which gives to the liquid a part of the required head, in the form of pressure, until it has attained a total pressure corresponding to the height to which it is to be pumped. In this way, from the simple centrifugal pump, is derived the high-pressure centrifugal pump, among which Messrs. Hayward-Tyler's pump possesses many advantages on account of its attaining the simplest and most practical solution of this subdivision of head.

The drawing Fig. 2 shows the Hayward-Tyler turbo high-pressure pump in section. There is a steel shaft (A) to which runners (B) are firmly fastened, while the guides or guide wheels (C) are attached to the surrounding casing (D), which is lined by a gunmetal liner. The liquid to be pumped enters the annular casing (E) and is then led by a stationary guide wheel to the first runner, and so on through a number of guides and runners until it at last escapes from

Digitized by Google

the casing (F) into the discharge pipe. The intake and delivery can be set in any position by the simple rotation of the inlet and discharge casings about the axis. The shaft revolves in self-lubricating bearings (G), both of which are completely protected by a special form of construction from the entrance of the liquid pumped. Both bearings may be easily examined while running and supplied with fresh oil. The axial thrust is completely balanced, so that pistons, valves, &c., are unnecessary; the working of this balance is so exact that neither ball nor collar thrust bearings

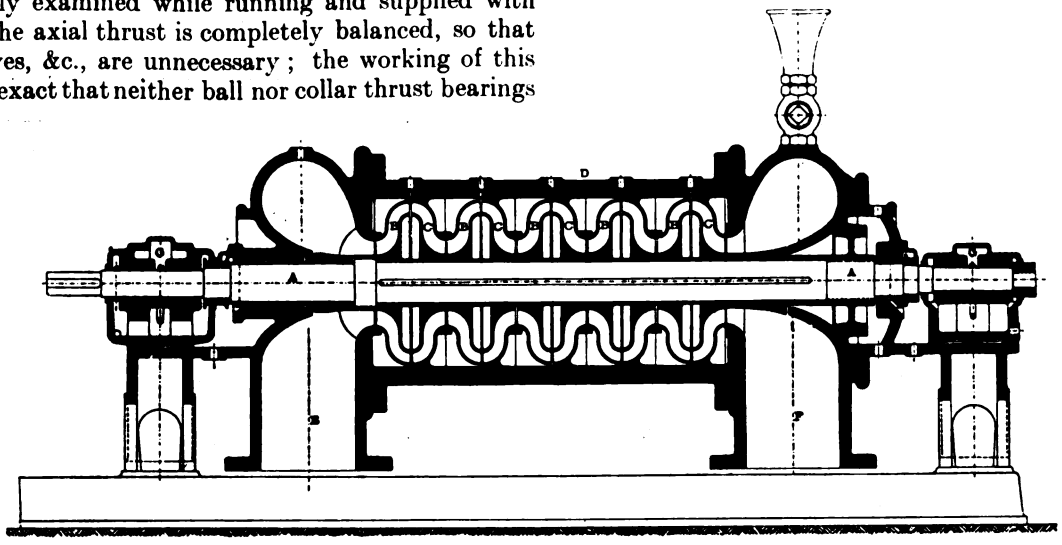

Fig. 2.—Section of Hayward-Tyler Turbo Pump.

are needed. As the liquid which is pumped flows continuously, and there are thus no fluctuations in pressure, such as are unavoidable with piston pumps, air chambers are rendered entirely unnecessary.

From a theoretical point of view, the simplicity with which the water is guided is at once noticeable. There are no avoidable losses from curvature, as the water passes through the pump by the shortest route, avoiding all unnecessary and sharp bends. This shortest route results from the fact that the necessary change in direction of flow is accomplished, half during the passage of the liquid from the periphery to the axis in the guides, and half in the passage in a reverse direction through the runner, so that the water enters and leaves the runner in an axial direction. The curves of the water channels can always be made as easy as

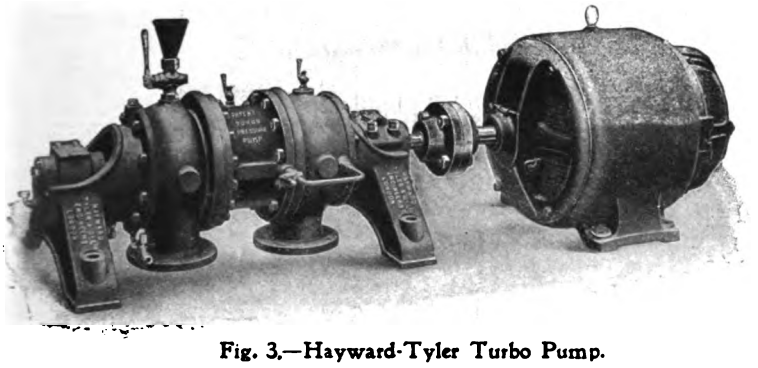

Fig. 3.—Hayward-Tyler Turbo Pump.

necessary, and this enables the losses from friction of the liquid against the sides of the channels in passing around the bends to be reduced to a minimum. Both in the guides and runners of these pumps there are vanes which guide the water throughout its entire course. The form of these vanes completely prevents the formation of whirls or eddies, and the consequent losses of power; whereas, in cases where the vanes are not continuous, the particles of the liquid, which must constantly change their direction of flow, would, beyond doubt, hit against one another, and waste a part of their velocity in eddies, so that a loss of power would result.

From a practical point of view, it will be seen that the assembling and erection of the turbo high-pressure pump are the simplest imaginable, so are not liable to derangement. The runners, each of which is separately and most carefully balanced on the shaft, can be pushed on to the smooth shaft by hand, and the pressure of a single nut, with check nut, is sufficient to fasten them firmly in position. In a similar manner the guide wheels are put into a smooth cylinder and firmly fastened in place by the end cover. The construction remains the same regardless of how many runners (2, 3, 4, 5, 6 or more) are needed, and for this reason it is easy to satisfy all requirements.

It requires only a few hours to take one of these machines apart and to put it together again, so that it is possible, without any considerable interruption of operations, to examine the condition of runners and guides and replace them if damaged. All wheels of any one machine have the same bore and external diameter, so that a mistake in erection is almost impossible, and a very small number of duplicate parts needs to be kept on hand. It makes no essential difference in the operation of the machine whether the axis

is horizontal or vertical, the latter arrangement being more suitable for pumps used for sinking wells or shafts.

The space required is smaller, a point which is of great importance in the case of underground pumping installations. As the diameter of the runner which produces the pressure is practically the same as that of the surrounding case, the pressure which is imparted to the liquid pumped is the maximum attainable with a given extreme diameter of

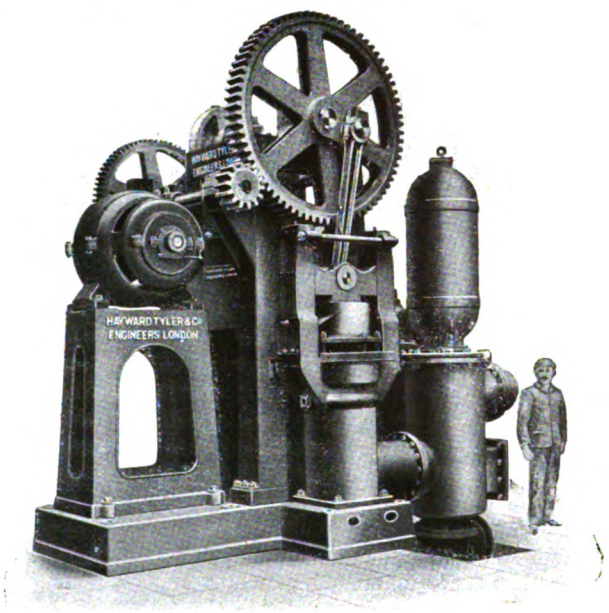

Fig. 4.—Hayward-Tyler Reciprocating Pump.

machine. Therefore each pump of this design can be built smaller and lighter than many pumps of similar design for the same head of capacity. On account of the absence of all opening and closing valves, and of the theoretically rational passage of the water through the machine, these pumps are noiseless. From the use of self-lubricating bearings, the attendance becomes extremely simple and does not require skilled labour. The machine has no moving parts which slide on each other, so that the greatest possible certainty of operation is assured, and in this respect its great superiority to the piston pump is evident. The method of operation to be chosen whenever possible is that of direct con-

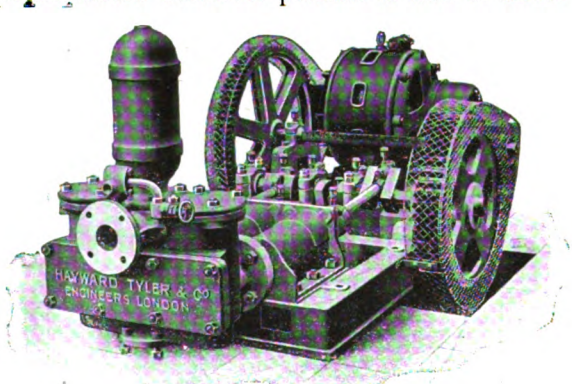

Fig. 5.—A Compact Reciprocating Pump.

nection with an electric motor or hydraulic or steam turbine. When this is impracticable, the pump may be driven by belts or ropes, or, in exceptional cases, by gearing. Messrs. Hayward-Tyler's standard types are built with special reference to the speed of electric motors.

Besides turbo-pumps, Messrs. Hayward-Tyler also manufacture treble-barrel pumps suitable for electric driving. Our illustrations show examples of these.

A New Blow-off Cock.

WE have been supplied by Messrs. James Baldwin & Co., of Keighley, with details of a new blow-off cock whose object is to elimimate all unequal expansion and pipe strains. The special feature of this blow-off cock, to which its makers have given the name of "Overall," consists in the formation of what is termed a

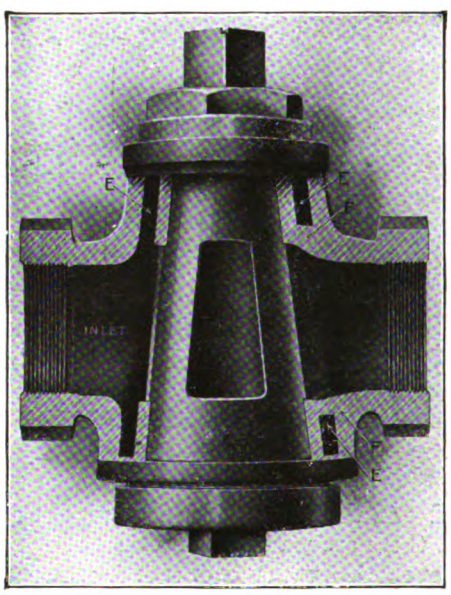

Fig. 1.—Section of Blow-off Cock.

temperature jacket, or space in the body of the cock forming an inner and outer shell, but there is only one casting. Fig. 1. shows a section of the cock. The taper plug C, which is ground in and not packed in any way, is shown in the shut position, the opening being at right angles to those in the body of the casting. It will be noticed that

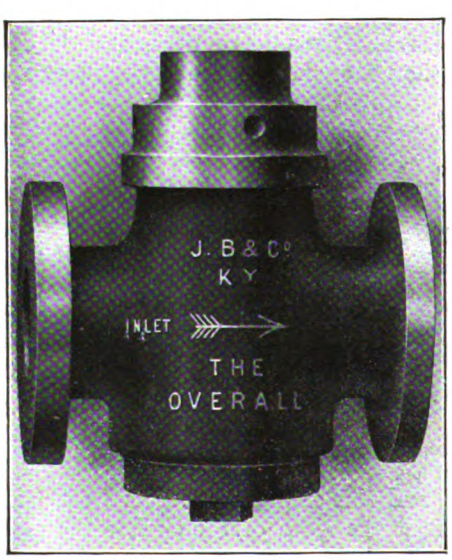

Fig. 2.—Inverted Type of Blow-off Cock.

there is a jacket or space E which extends completely round the body. There are thus an inner and an outer casing surrounding the plug, with the exception of at the parts marked F, where it is obviously necessary to have solid in order to form a partition between the inlet and outlet. Owing to this construction, the steam or other fluid at the inlet circulates in the jacket, thus maintaining the casing and the plug at an equal temperature under all

Digitized by Google

conditions of service, and thus, it is claimed, allowing the plug to move freely and to prevent it sticking.

It is pointed out by the makers that owing to the use of plug cocks, pipe stresses and strains caused by expansion, &c., are a source of trouble and give rise to leakage. This, it is maintained, arises from the fact that the bodies of ordinary cocks are solid and consequently rigid. It will be gathered that the inlet pipe is only connected to the outer shell of this new cock, which gives rise to a certain amount of flexibility. It is only the outlet pipe which is in rigid connection with the plug.

The makers have recently carried out a test on a 2 in. cock of this type. The cock was first subjected to high pressure steam, when it was found to be perfectly tight; that is, as regards leakage. It was then allowed to cool down whilst under pressure, when it was found that the plug could be moved slowly half a turn from the shut to open and open to shut positions with a lever 8 in long. Our illustration (Fig. 2) shows an inverted plug type of blow-off cock fitted with a locking gland. These cocks are made in sizes from ½ in. upwards.

Simplex Fans.

AT this sultry season of the year attention may be called to the cooling breezes engendered by Simplex fans which are made in all the usual types, shapes and sizes. They are neat and compact, and their general design can be gathered from the accompanying illustration.

Simplex fan motors receive the same winding for all voltages between 100 and 120 volts, also between 200 and 230 volts, and the alternating current and three-phase types are the same for all periodicities between 40 and 60 cycles per second. The outputs are, therefore, approximately proportional to the pressures and inversely proportional to the periodicities. As far as possible, the motors and fans are also wound for abnormal voltages, periodicities and speeds. Simplex direct-current motors are distinguished by their elegant design and are so constructed that they combine, it is claimed, an unusually high efficiency with low weight, great stability and small dimensions. By the application of a laminated field-frame of special form the losses are reduced and the commutation is considerably improved. All current-carrying parts are insulated in the most careful manner. The smaller types are exclusively supplied with automatic grease lubrication; in the larger

Typical Simplex Table Fan.

types either ring or grease lubrication is used. When desired, the motors can be totally enclosed, in which case the output is about 75 per cent. of that of the open-type motors.

The smaller alternating-current types of fan motors are series wound and are fitted with a highly insulated sector commutator. By the introduction of a finely laminated field-frame of special form, the losses and heating are considerably reduced, whereby a very high efficiency is attained. The single-phase commutator motors and fans can be connected to one of the three phases of a three-phase network. The regulation of the single-phase commutator motors is effected in the same way as in the case of the direct-current types. The alternating current and three-phase motors from ⅛ H.P. upwards are asynchronous motors and consist of a laminated stator, which carries the winding, and a short-circuited rotor. The starting of the alternating current single-phase motors is carried out by means of an automatic arrangement incorporated in the winding of the stator. All the alternating current motors can be at once set to work by means of simple switches.

NOTES.

The I.E.E. Council Election.

As is already known to our readers, the Council's nominations for the election of members of Council of the Institution have this year been challenged by an outside nomination, Mr. H. FARADAY PROCTOR being selected as candidate for this purpose. Last week the election was held and resulted in the return of Mr. PROCTOR in place of Mr. J. E. KINGSBURY, the figures of the ballot for the five vacancies being as follows:—

P. V. McMahon	854	R. K. Morcom	842
S. L. Pearce	852	H. Faraday Proctor.....	696
H. Dickinson	846	J. E. Kingsbury	438

AT the outset we wish it to be clearly understood that we are in favour of outside nominations, if properly conducted, as they check any tendency for the Council to develop into a clique, of which there must always be some danger when nominations are made by a Council alone. The question arises whether it was desirable that such a step should have been taken at the present time. We think most people will have felt that it was unnecessary, as the Council's nominations gave general satisfaction. But supposing the step to have been desirable in principle, was it suitable that a provincial member should have been selected? It appears to us, and doubtless to many others, that such a selection was unjustified, having regard to the fact that three representatives of local sections had already been nominated by the Council. It must not be forgotten that chairmen of local sections are *ex officio* members of Council; there are thus six such *ex officio* members, who, together with three local section members nominated by the Council, make a total of nine out of a body of 28 vice-presidents and members who are subject to change by election. It must be admitted, then, that the provincial members have a considerable voice in the affairs of the Institution. If this proportion in the provincial representation is to be much exceeded, then the Council should be enlarged, for it is obvious that provincial members cannot attend meetings with the same regularity as those in London, and thus the working Council becomes reduced.

ALTHOUGH, of course, we have no feeling against Mr. PROCTOR, and we do not doubt that he is well qualified to serve the Institution, we must, nevertheless, take very strong exception to the way in which his candidature has been urged. A letter signed by Mr. W. A. CHAMEN, a copy of which will be found elsewhere in this issue, was sent to *selected* members of the Institution, enumerating Mr. PROCTOR'S qualifications, and pointing out among other things that he belongs, as is indeed suggested by his name, to the family of the famous Michael Faraday. Except to those who are strong believers in heredity, this seems scarcely a serious recommendation, for surely a seat on the Council depends upon personal merit quite independently of one's grandparents. This, however, is but a small matter. The important part of the letter is where members are asked specifically to vote against one particular candidate, namely, Mr. KINGSBURY. As pointed out recently in our Correspondence columns, the canvassing

Digitized by Google

of selected members is bad enough and is highly undesirable if the dignity of the Institution is to be maintained; but when we come to definite instructions for the blackballing of a particular candidate, the whole thing savours of political warfare and cannot be too strongly condemned.

A GLANCE at the ballot figures is enough to show that a large number of papers were sent in with every name struck out except that of Mr. PROCTOR. There is much to be said in favour of issuing balloting lists which need not be returned with a full list of candidates, so that members need only vote for those whom they know, but this weapon should not be used for what may be best described as party purposes. We cannot help thinking that Mr. PROCTOR will feel a little uneasy in his seat at the Council table after the means that have been used to secure his election. If we are to have outside nominations, at least let the procedure be open and aboveboard; otherwise the final result will be far worse than with Council nominations alone, for the Institution will suffer by continual wire-pulling, and will inevitably cease to attract the most desirable elements of the profession.

Electricity Supply at Grimsby.

SEVERAL points of interest are contained in the annual report of Mr. W. A. VIGNOLES on the progress made by the Grimsby Corporation Electricity Department during the past year. In the first place, it is very satisfactory to notice that increased sales are recorded in each branch of the supply; and as the number of units sold for private lighting has increased in approximately the same ratio—9 per cent.—as the number of lamps connected, whereas during recent years the revenue did not keep pace with the growth of the connections, it is probable that the majority of consumers who are likely to adopt metal lamps have already done so. In regard to power supply, the number of units sold has increased by no less than 36 per cent. compared with the previous year's sales, but in this connection it must be remembered that a year ago the demand for power had been affected by the depressed state of trade. Attention may be called to the fact that out of 1,065 H.P. of motors connected to the mains, 395 H.P. is on the restricted hour system, 206,625 units having been sold on this basis during the past 12 months.

STATISTICS as to the operation of arc lamps for street lighting are not always easy to obtain; the figures given by Mr. VIGNOLES are, therefore, of interest. He mentions that of the 230,408 lamp-hours during which the open type arc lamps were in use, the lamps were reported "out" for 1,564 lamp-hours—that is, 0·68 per cent. of the total. The existing arc lamps, however, are to be changed to flame lamps, the cost of the alteration to be met out of the profits of the undertaking, and we do not doubt that Mr. VIGNOLES' estimate of considerably improved results as regards "extinctions" will be realised. In view of the heavy penalty attaching to "extinctions" in the recent Westminster street lighting contracts, it is not unlikely that greater attention will in future be paid to the recording and minimising of failures.

Loans for Service Mains.

As is well known, the attitude of the Local Government Board has of recent years become more critical in regard to the sanctioning of loans for electricity supply undertakings, and certain expenditure, which at one time would have been placed to capital, has now to be met out of revenue. At a Local Government Board inquiry at Grimsby some little time ago the inspector intimated that money borrowed for service mains would in future have to be repaid in 15 years. This step is only in keeping with the present tendency of the Board to restrict the period for which loans are granted and to refuse loans for small expenses. It will be remembered that loans for mains have hitherto been sanctioned for a term of 30 years; where, however, loans can only be obtained for short periods it may sometimes be preferable to endeavour to meet the expenditure out of revenue. Under the circumstances mentioned above, Mr. VIGNOLES has recommended the Committee to consider the question of adopting this course for the laying of services at Grimsby. There is little doubt, however, that such a policy must tend at times to restrict the expansion of an undertaking, especially in its early years. In this connection it will be remembered that the Board have already required that meters should be provided out of revenue, so we hope a similar policy will not be pushed too far.

Fiscal Discussion.—We are asked by the National Electrical Manufacturers' Association to draw attention to the adjourned discussion on the Comparative Effects of Free Trade and Protection upon the Electrical Industry, which will take place on Monday next at Caxton Hall, Westminster, S.W. The chair will be taken at 8 p.m. by the chairman of the Association, Mr. H. W. Butler, and the discussion will be resumed by Mr. E. Garcke.

"Illumination of Interiors."—A course of three lectures on this subject will be delivered at the East London College on Wednesdays, June 8th, 15th and 22nd, at 8 p.m., the first two being given by Prof. J. T. Morris, and the third by Prof. C. A. M. Smith. The first lecture will deal with "Principles and Daylight Illumination," the second with "Artificial Illumination by Gas and Electricity," and the third with "Illumination by Petrol Air Gas." Admission to this course is free, and application for tickets should be made to the Registrar.

Street Lighting.—In last week's issue of the "Journal of Gas Lighting" the writer of "Electricity Supply Memoranda" makes some disparaging remarks about the Jandus regenerative arc lamp and recent victories achieved by that lamp over high-pressure gas. Reference is also made to an interview with Mr. A. Denman Jones, manager of the Jandus Arc Lamp & Electric Co., which appeared a short time ago in our columns. In the correspondence columns of our present issue will be found a letter in which Mr. Denman Jones replies to the criticism of our contemporary, and gives some interesting figures.

Obituary.—ALFRED COLSON.—We regret to record the death of Mr. Alfred Colson, which occurred at Leicester on Friday last. The deceased was gas and electric light engineer to the Leicester Corporation. Mr. Colson was born in 1854, and received his early engineering education under his father, who at that time was engineer to the London & South-Western Railway. After finishing his apprenticeship he took up gas engineering in London, and held a position at one of the large metropolitan gas works. In 1872 he moved to Birmingham, becoming assistant engineer to Mr. Chas. Hunt, one of the most celebrated gas engineers of his time. In 1882 Mr. Colson was appointed gas engineer at Leicester, a position he was holding at the time of his death. During the 10 years of his office he carried out a number of extensions to the works, and generally improved the method of manufacture and distribution. In 1893 the Leicester Corporation decided to erect works for the supply of electricity. These were built under Mr. Colson's superintendence, and when they were finished he was placed in charge of the electricity supply in Leicester. Although several years ago he was offered the position of engineer-in-chief of the Gas Light & Coke Co., he preferred to remain at Leicester. He was the inventor of many patents, and his services as consulting engineer on gas questions were frequently sought.

Insulating Materials for Wireless Telegraphy.—At a meeting of the Wireless Institute, held at the Engineering Societies' Building, New York, on May 4, Mr. S. M. Hills read a Paper dealing with materials for resisting dielectric stress, mechanical rupture, flow of electricity and heat, and the action of chemicals. He gave an outline of the electrical, mechanical and chemical characteristics of air, oil, marble, hard-rubber, porcelain, glass paper, mica, wood, lava and various compositions. He stated that where the distance was not limited, dry air formed a good insulator, and compressed air could be used where high voltages were encountered. Dry oil made an excellent insulator on account of its self-healing properties. Hard rubber was apt to deteriorate with age. Marble was hygroscopic and irregular in mechanical characteristics. Porcelain was surprisingly strong mechanically, but was apt to possess unknown defects. Glass was very fragile, but its defects were visible upon superficial examination. Mica was extremely good for localities where oil or moisture would not be encountered. Wood was a good insulator when kept perfectly dry and it had good mechanical properties. Mr. R. H. Marriott remarked that hard rubber and wood were frequently used for strain insulators in the guys for wireless masts. Oak had proved good for this purpose. In some of the early stations use was made of rope for strain insulators. Porcelain compression insulators had many excellent characteristics for wireless installations. Mr. A. N. Goldsmith described the use of an insulating material of lava which could be moulded into any desired shape and then baked to form an insulator possessing excellent electrical, mechanical and chemical properties. Mr. J. J. Frank mentioned the fact that moisture was detrimental to the performance of practically all insulators. A very small percentage of moisture greatly lowered the insulating strength of oil. Solid insulators could be kept free from moisture by maintaining them at a temperature higher than their surroundings or blowing warm, dry air across them.

The Corrosion of Metals.—We understand that the Council of the Institute of Metals have decided to undertake an investigation into the causes of the corrosion of non-ferrous metals by sea water, acids, &c., and by other chemical and electrolytic reactions. A committee has been appointed for the purpose of carrying out the investigation, and at their first meeting decided in the first instance to confine their attention to the question of the corrosion of condenser tubes in marine engines and in stationary engines using foul water or subject to violent electrolytic action, such as often occur in electric power stations. Before commencing experimental research, the committee propose to have prepared an epitome of such information on the subject as is already available from previous research in the same direction. Mr. G. D. Bengough, of the metallurgical department of the University of Liverpool, has been asked to undertake this work and to become a member of the committee. On the completion of the work by Mr. Bengough it will be submitted to the committee, who will then consider what steps shall next be taken in the matter of further investigation and experimental research, with a view to elucidating the various mysteries of corrosion which are the source of so much trouble and anxiety both to users and manufacturers of articles composed of copper and its alloys. Prof. H. C. H. Carpenter, M.A., Ph.D., of the University of Manchester, whose work for the "Alloys Research Committee" of the Institution of Mechanical Engineers is so well known and highly appreciated, has kindly undertaken to act as honorary secretary to the committee. The result of the committee's researches will be at the disposal of members of the Institute of Metals, which already includes in its membership most of the leading manufacturers and users of non-ferrous metals; and, doubtless, those who have not as yet thought it worth their while to associate themselves with the Institute will, in view of the useful and most important work which it has now initiated, be anxious to join its ranks. This trouble of corrosion is one which has long given infinite cause of annoyance and anxiety to all who have to deal with non-ferrous metals, and above all to marine engineers, and it cannot fail to be a matter of general congratulation amongst engineers that the solution of the problem has now been undertaken seriously by a body so competent to deal therewith as the Institute of Metals, which comprises within its membership makers, users and scientists, and, therefore, has at its disposal information such as no other body possesses or could hope to possess.

Electricity Supply in Brussels.—According to "The Times Engineering Supplement," the extra traffic arising in consequence of the Exhibition has made an extension to the generating plant of Brussels a necessity, and it has been decided in view of the increase in connections to extend considerably the output of the station. The equipment consists of five four-cylinder tandem compound reciprocating engines of the horizontal type, each driving a 1,500 kw. alternator. The most economical load of four of these, however, is only 1,100 kw., and as the *maximum* demand for power before the opening of the Exhibition sometimes amounted to 6,600 kw., it was evident that additional plant was urgently required. After considerable discussion, it was decided to instal a 4,000 kw. turbo-alternator, and the machine was recently set to work. The normal speed of the turbine is 1,500 revs. per min., which is high for this power, and hence the machine is relatively small. There are seven nozzles, all of which are automatically opened and closed by means of the governor, being mounted on a vertical spindle, which is raised or depressed with the governor sleeve. On this vertical spindle are projections which, as the spindle descends, force the horizontal nozzle valve spindles to move inwards and thus to open the nozzles in pairs as the load increases. The speed of the machine can be raised by hand by increasing the pressure on the governor balls, and the same operation can be performed from the switchboard through a small electric motor which operates the same handwheel. There is an automatic runaway governor which shuts off steam from the turbine when the speed reaches 1,660 revs. per min. The working pressure at the stop valve is nine atmospheres (10 at the boilers), and the temperature of the steam is 325°C. The overload capacity is 5,000 kw. for one hour, and the steam consumption is 13·7 lb. per kilowatt-hour at normal load, against a guarantee of 13·8 lb. The existing steam engines take 14·3 lb. per kw.-hr., and there is already a daily saving of about 5 tons of coal, which has caused the directors to consider the question of replacing the reciprocating engines by another turbine. The alternator, the working pressure of which is 6,600 volts, is totally enclosed, except for an air inlet at the bottom and outlet at the top, and the air is drawn in from an enclosed brick chamber underneath, where it has to pass through many rows of filtering cloths before being drawn into the alternator casing, thus avoiding any possibility of damage to the insulation through dust. In accordance with the usual practice,

Digitized by Google

the condenser is directly underneath the turbine, and the air and water circulating pumps are both driven by a 100 H.P. turbine (one on each side) at 1,400 revs. per min., the air pump being of a rotary type. The pump for returning the condensed water to the boilers is also driven by a small steam turbine at 5,000 revs. per min., but the water can also flow to waste if desired. The turbine runs excellently in parallel with the reciprocating engines, and will no doubt be the forerunner of many similar installations in some of the larger and older tramway stations.

Telephone Train Despatching on the Great Northern Railway of America.—According to the "Electrical Review and Western Electrician," the Great Northern Railway, which at the present time is using the telephone to dispatch its trains on divisions covering approximately 2,100 miles of its line, is now planning a further extension of this system. The apparatus to be installed will be the Cummings-Wray selectors and Western Electric telephones, as this style of equipment has been adopted as standard by this railway, and is now in use on the present circuits. Two hundred and ninety stations will be completely equipped for the new class of service. An interesting feature of this installation will be the placing of telephones at sidings and at stations which are not open during the whole 24 hours, 350 telephones being required. While the train crews in this way can reach the dispatcher at any time, the important fact is that the dispatcher can get in touch with the train crews waiting at any siding.

Electricity in a Gas Company's Building.—The "Electrical World" states that the new building of the People's Gas Light & Coke Co. in Chicago will be supplied with both electricity and gas for lighting purposes. The Commonwealth Edison Co. will furnish the electrical energy, and the building is being wired for about 18,500 16 c.p. incandescent electric lamps and 1,400 H.P. in electric motors for lifts and other purposes. There will be 15 electric lifts, including 14 for passengers and one for goods. These lifts will be of the recent one-to-one traction type made by the Otis Elevator Co. In addition, there will be motors to drive ventilating fans, blowers, house pumps, coal conveyers, centrifugal pumps, vacuum pumps, &c. Such a large amount of electricity will be required for the general purposes of this building that the contract for supplying it is based on the central station company's regular wholesale schedule for light and power. This schedule applies only to large users of electricity, and in ordinary cases office buildings do not fall within the rates which it provides. Tenants will have the option of using electricity or gas, or both, for lighting. The gas company itself will use gas for lighting its offices and salesrooms, as may be imagined. A portion of the building is now occupied, and temporary gas fixtures are in place. Ultimately, however, all fixtures in tenants' rooms will be combination fixtures, so arranged that the gas lighting will be indirect and the electric lighting direct. Mantles will be attached to the gas burners, of course, and it is probably the theory of the gas company that the indirect gas lighting will be pleasing to tenants and more economical than the electric light. The actual results of the experiment—that is, the proportion of tenants using the gas and electric light, respectively—will be of interest when the building is fully occupied and sufficient time has elapsed to enable the tenants to make an intelligent choice.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. C. V. Drysdale contributes an article on "The Determination of the Efficiency of Direct-Current Machines" by the Hopkinson test.

We give an account of the electrical features of the main drainage scheme in Glasgow.

At the election of the Council of the Institution of Electrical Engineers last week the outside nomination (as distinct from nominations by the Council) of Mr. H. Faraday Proctor was successful.

At the meeting of the Institution of Electrical Engineers last week the Annual Report of the Council was presented.

We conclude our abstract of the Paper on "Standardisation of Fuses," read by Mr. H. W. Kefford before the Birmingham local section last week.

We give a further account of the electrical exhibits at the Brussels Exhibition.

Ventnor (Isle of Wight) Council have decided to consider the question of constructing an electric tramway in the district.

The Board of Trade arbitrator, Mr. S. Buckmaster, K.C., has given his award in the dispute between Stretford Council and Manchester Corporation as to the supply of electrical energy for abnormal traffic on the Stretford lines, caused by football matches, &c.

Extensions of the Sheffield electricity supply works are to be carried out at an estimated cost of £78,000.

Legal.—In the action Wheeler *v.* Marylebone (London) Borough Council, plaintiff recovered damages for injuries caused to plaintiff by coming into contact with a service cable in a house which he was demolishing preparatory to rebuilding.

Companies' Meetings.—At the meeting of the Anglo-Argentine Tramways Co. on Wednesday, resolutions were passed increasing the capital by £8,000,000 to provide for the construction of new subway lines in Buenos Ayres, &c.

INSTITUTIONS AND SOCIETIES.

THE INSTITUTION OF GAS ENGINEERS.—The annual general meeting of this Institution will be held in the hall of the Institution of Mechanical Engineers, at Westminster, under the presidency of Mr. J. W. Helps, Engineer and General Manager to the Croydon Gas Co., on Tuesday, Wednesday and Thursday, June 14 to 16. The president's address will be delivered at the opening of the proceedings, after which a Paper on "Public Lighting from a Municipal Point of View," by Mr. Jacques Abady, will be read and discussed. Other Papers on subjects of interest to gas engineers will be dealt with on the subsequent days.

SOCIETY OF CHEMICAL INDUSTRY.—The Scottish Section of this Society will hold their annual meeting in Glasgow from July 6th to 8th inclusive.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, June 4th.

ROYAL INSTITUTION.

3 p.m. Lecture on "Electric Heating and Pyrometry," by Prof. J. A. Fleming, F.R.S. (The Tyndall Lectures.) (Lecture I.)

MONDAY, June 6th.

NATIONAL ELECTRICAL MANUFACTURERS' ASSOCIATION.

8 p.m. Meeting at Caxton Hall, Westminster. Adjourned discussion on "The Effect of Free Trade or Protection upon the Electrical Industry," to be opened by Mr. E. Garcke. Admission will be by visiting card.

THURSDAY, June 9th.

TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION.

10:30 a.m. Congress at Dublin. (Headquarters Imperial Hotel.) Official reception; followed by the reading of Papers.

FRIDAY, June 10th.

TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION.

Congress at Dublin. Visits to power station, &c.

PHYSICAL SOCIETY.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute Road, South Kensington. Agenda: "A Galvanometer for Alternate Current Circuits," by Messrs. W. E. Sumpner and W. C. S. Phillips, and "The Positive Electrification due to Heating Aluminium Phosphate," by Mr. A. E. Garrett.

SATURDAY, June 11th.

ROYAL INSTITUTION.

3 p.m. Lecture on "Electric Heating and Pyrometry," by Prof. J. A. Fleming, F.R.S. (The Tyndall Lectures.) (Lecture II.)

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

Monday, June 6th. "A" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Technical Drill, 7 to 9:30 p.m.

Tuesday, June 7th, "B" Company.—Technical Drill, 7 to 9:30 p.m.

Wednesday, June 8th.—Gymnasium, 6 to 9:30 p.m.

Thursday, June 9th, "C" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Technical Drill, 7 to 9:30 p.m.

Friday, June 10th, "D" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Technical Drill, 7 to 9:30 p.m.

Saturday, June 11th.—Musketry at Runemede. This course is now compulsory. Names must be sent in as soon as possible for this shoot. Next shoot after this, July 30th.

Digitized by Google

INSTITUTION OF ELECTRICAL ENGINEERS.

At the general meeting held on Thursday evening last week at the Royal Society of Arts, the chair was taken by Mr. W. Duddell, F.R.S., who read a letter from the president, in which Dr. Kapp stated that he regretted that he was unable to be present, but he hoped to be about again in a fortnight's time.

Mr. Duddell moved that the following resolution of the Council be adopted by the Institution. "That the Council of the Institution of Electrical Engineers, in special meeting assembled, hereby record their sense of the deep loss which the British Empire has sustained through the lamented death of His Majesty King Edward VII., and their sorrow that one who spent his life for the good of his people, and to whom his subjects were affectionately devoted, has been removed from the scenes of his unremitting labours, and that a reign marked by unparalleled social, scientific and industrial progress has thus been brought to a close.

"The Council humbly beg permission to express to His Majesty King George V., the Queen Mother, and to the Members of the Royal Family, their sincere condolence and sympathy, and further to lay before His Majesty the assurance of their unswerving loyalty and devotion, and their earnest wishes that he may, with Her Majesty Queen Mary, long be spared to reign in happiness and peace over a loving and united people."

This resolution having been adopted, Messrs. W. A. Chamen, R. J. Wallis-Jones, C. S. Thomson and R. W. Hughman were appointed as scrutineers of the ballot for the election of five new members of Council. At the conclusion of the meeting the result of this ballot was declared as follows :—

P. V. McMahon	854	votes.
S. L. Pearce	852	,,
H. Dickinson	846	,,
R. K. Morcom	842	,,
H. Faraday Proctor	696	,,
J. E. Kingsbury	438	,,

The Council for the session 1910-11 will therefore be as given in our issue of April 22nd, except that Mr. H. Faraday Proctor's name must be substituted for that of Mr. J. E. Kingsbury.

In moving the adoption of the annual report of the Council, of which an abstract is given below, the chairman called attention to the more important points mentioned therein; and after Mr. Robt. Hammond had dealt with the statement of accounts for the past year, the usual votes of thanks to the Institution of Civil Engineers and the Royal Society of Arts, and to the officers of the Institution were moved and adopted.

As the scrutineers of the ballot had not completed their task, the meeting adjourned and a special general meeting was held to pass the following resolution :—

"That, in addition to the sum of £20,000 authorised by special resolution of July 29, 1909, to be expended, a further expenditure of a sum not exceeding £10,000 in connection with the Institution building on (*a*) structural alterations, furniture and fittings, and (*b*) outlays during present or future structural alterations, including ground rent, rates and taxes, less rents received or to be received from tenants in the building, be sanctioned and approved, and that the Council be authorised to make such financial arrangements (including the borrowing of money on the security of the Institution building and on the Institution property in Tothill-street) as the Council may consider necessary for the above purpose."

Mr. Hammond explained that there had been a considerable loss on the sale of securities in providing funds for the new building. This loss, he thought, should form part of the cost of providing the new building. If this were done, however, the Council's estimate was exceeded by £1,100 to £1,200. In order to obviate the need for special meetings in the future to sanction any expenditure which might have to be met within the next two or three years, the Council asked for authority to expend a sum not exceeding £10,000, although it was not expected that anything approaching this amount would be required.

The chairman then moved the above resolution, which was seconded by Mr. Kaye Gray. Mr. W. B. Esson asked Mr. Hammond for an explanation of the reason why the original estimate of the Council had increased to such an extent. In this connection he drew Mr. Hammond's attention to his (Mr. Hammond's) statement two years ago that £56,000 was to be the total cost of the new building, whereas now the Council were asking for sanction to expenditure which would bring the total cost to £80,000.

Mr. Hammond, in reply, explained that on taking over the building and going more fully into the question the Council found that drastic alterations would be required to the theatre if the members were to obtain a first-class result, which there was no doubt they desired. At the first opportunity (July 29, 1909) the Council explained the position to members and asked for sanction to the expenditure of £70,000. This sum had merely been exceeded by, say, £1,100-£1,200. In reply to Mr. W. R. Cooper, Mr. Hammond stated that the £10,000 now in question was not to be used (except approximately to the extent of the small sum mentioned) for the alterations now in progress.

No further questions being asked, the resolution was put to the meeting and passed unanimously. The adjourned annual meeting was then resumed, and the result of the ballot for the election of five members of Council was declared as above. This concluded the business of the meeting.

The following is an abstract of the report of the Council :—

Growth of the Institution.—Since the last annual general meeting, 505 proposals for election have been considered, and there have been elected 8 members, 215 associate members, 6 associates, and 233 students. To the class of members there have been transferred 39 associate members and 12 associates, to the class of associate members 28 associates and 117 students, and to the class of associates 3 students. The total roll is now 6,222, compared with 6,097 in the previous year, and is composed of 7 honorary members, 1,173 members, 2,629 associate members, 938 associates, 1,370 students, and 105 foreign members.

Among well-known members who have died since the last annual general meeting are Sir Charles Todd, K.C.M.G., F.R.S. (local hon. secretary and treasurer for South Australia from 1881 to 1906), Mr. Shelford Bidwell, F.R.S., Major P. Cardew, R.E., Mr. Hugh Erat Harrison, B.Sc., and Mr. J. Oldham (local hon. secretary and treasurer, Uruguay).

Meetings and Papers.—During the past session 15 general meetings, 2 special general meetings, and 19 council meetings have been held. There have been 45 meetings of local sections, viz., 7 at Birmingham, 7 at Dublin, 7 at Glasgow, 11 at Manchester, 6 at Newcastle, and 7 at Leeds and Sheffield. A complete list of Papers and original communications, with the places where read, is given in the report.

Scholarships.—The Council have awarded a Salomons Scholarship of the value of £50 to Brian Charles Clayton, of King's College, and David Hughes Scholarships, of the value of £50 each, to George Wood Pearce Page, of the Central Technical College, and to Archibald Davidson Peacock, of University College.

Premiums.—The Premiums for Papers and communications have been awarded as follows: The Institution Premium, value £25, to Mr. Miles Walker, for his two Papers, "Short Circuiting of Large Electrical Generators and the Resulting Forces on Armature Windings," and "The Design of Turbo Field Magnets for Alternate-current Generators, with Special Reference to Large Units at High Speeds"; the Paris Electrical Exhibition Premium, value £10, to Prof. A. Schwartz, for his Paper, "The Testing of Rubber for Electrical Work"; the Fahie Premium, value £10, to Mr. S. G. Brown, for his Paper, "A Telephone Relay"; a Premium, value £10, to Messrs. W. P. Digby and D. B. Mellis, for their Paper, "Some Properties of Switch and Transformer Oils"; a Premium, value £10, to Mr. G. W. Worrall, for his Paper, "Commutation Phenomena and Magnetic Oscillations Occurring in Direct Current Machines"; a Premium, value £5, to Mr. F. Hope-Jones, for his Paper, "Modern Electric Time Service"; a Premium, value £5, to Mr. F. H. R. Lavender, for his Paper, "Research on Metallic Filament Lamps"; a Premium, value £5, to Mr. Albert Campbell, for his original communication, "On Magnetic Testing of Iron with Alternating Current"; a Premium, value £5, to Mr. C. F. Smith, for his original communication, "The Relation between the Stator and Rotor Circuits of the Single-phase Induction Motor"; a Premium, value £5, to Mr. L. W. Wild, for his original communication, "The Production, Measurement, and Effect of Variable Wave-Form." The Council have also awarded the Willans Premium (of which an award is only made every sixth year) to Mr. J. H. Rider, for his Paper, "The Electrical System of the London County Council Tramways." Students' Premiums have been awarded to Messrs. R. C. Plowman, A. P. Young, P. J. Cottle, J. A. Rutherford, P. Kemp, W. A. Stephens, and W. H. Young.

Students' Section.—At the opening meeting of the session an address to the students was delivered by Mr. J. H. Rider on the subject of "The

Digitized by Google

Importance of Attention to Detail." Ten meetings of the Students' section have been held in the library of the Institution, at which Papers were read and discussed. The Students' committee organised a very successful visit to Berlin in the summer of 1909. The Glasgow and Manchester branches of the Students' section have each completed a successful session, having held six and nine meetings respectively.

The Institution Building.—The structural alterations necessary to adapt the building to the requirements of the Institution have been in progress since August of last year. It is expected that the offices will shortly be transferred to the building, and that the lecture theatre, library, and members' rooms will be ready in time for the opening of the new session.

The British Electrotechnical Committee.—The British committee for 1910 is constituted as follows: The Council for the time being of the Institution, with the addition of Mr. K. Edgcumbe, Mr. S. Z. de Ferranti, Mr. C. D. Le Maistre, Mr. H. W. Miller, Lord Rayleigh, O.M., F.R.S., Capt. H. R. Sankey, R.E. (ret.), Mr. C. P. Sparks, Mr. A. P. Trotter, and Mr. E. B. Vignoles. In view of the removal to the new building it was felt that it would be an advantage to transfer the work of the committee to the Institution. The committee having given their consent, the transfer was effected in January of this year, and the work is now carried on in the offices of the Institution. During the last session the committee and its sub-committee on Nomenclature and on Symbols have held eight meetings and have made satisfactory progress.

An informal meeting of the Electrotechnical committees of the various countries will take place at Brussels next August. This will afford an opportunity for an exchange of views, and will considerably facilitate the work of preparation of the several committees for the official international meeting arranged to take place in Berlin in 1911.

Wiring Rules.—The revision in progress has been carried further than was at first intended. By the kindness of Dr. R. T. Glazebrook, F.R.S., Director of the National Physical Laboratory, tests are being made with reference to certain data in the rules. It is hoped that the revised edition will be ready before the end of the year.

Model General Conditions for Contracts.—The conditions which were issued in 1903 are under revision.

Professional Conduct.—The Council have decided to adopt the regulations relating to professional conduct recently incorporated in the by-laws of the Institution of Civil Engineers, and subject to the proposal receiving the sanction of a special general meeting of members and associate members, these regulations will be embodied in the articles of association and be applicable to members of all classes. The regulations are as follows:—

Every member of the Institution shall observe and be bound by the following regulations: (1) He shall act in all professional matters strictly in a fiduciary manner with regard to any clients whom he may advise, and his charges to such clients shall constitute his only remuneration in connection with such work, except as provided by clause 4. (2) He shall not accept any trade commissions, discounts, allowances, or any indirect profit in connection with any work which he is engaged to design or to superintend, or with any professional business which may be entrusted to him. (3) He shall not, while acting in a professional capacity, be at the same time, without disclosing the fact in writing to his clients, a director or member of, or a shareholder in, or act as agent for, any contracting or manufacturing company or firm or business with which he may have occasion to deal on behalf of his clients, or have any financial interest in such a business. (4) He shall not receive, directly or indirectly, any royalty, gratuity, or commission on any patented or protected article or process used on work which he is carrying out for his clients, unless and until the receipt of such royalty, gratuity or commission has been authorised in writing by those clients. (5) He shall not improperly solicit professional work, either directly or by an agent, nor shall he pay, by commission or otherwise, any person who may introduce clients to him. (6) He shall not be the medium of payments made on his clients' behalf to any contractor or business firm (unless specially so requested by his clients), but shall only issue certificates or recommendations for payment by his clients.

Any alleged breach of these regulations, or any alleged professional misconduct by a corporate member which may be brought before the Council, properly vouched for and supported by sufficient evidence, shall be investigated, and if proved shall be dealt with by the Council either by expulsion of the offender from the Institution or in such other manner as the Council may think fit.

Examinations for Associate Membership.—A committee has been appointed by the Council to consider and report on the question of an examination for associate membership.

Articles of Association.—As no alteration has taken place in the articles of association for the past five years, a committee has been appointed to consider and to report whether any alterations are necessary, and any suggestions which the members may desire to make will be welcome.

Electricity in Mines.—A number of suggestions were received from members and were carefully considered. A letter embodying the Council's views and recommendations was forwarded to the Home Office committee. Mr. W. H. Patchell also attended at the Home Office and gave evidence on behalf of the Council.

Electricity in Textile Mills.—A committee appointed by the Council to report on the question of electrical driving in textile mills are at present engaged in collecting the data available in collaboration with the local sections interested.

Building Fund.—The attention of members generally is called to this fund. The Council hope that there will be a large increase in the number of contributors, and they wish to point out the importance, in the aggregate, of even small annual subscriptions.

Benevolent Fund.—The committee of management report that the benevolent fund of the Institution shows a satisfactory increase for the past year. On December 31, 1909, the capital account of the fund stood at £3,500, as compared with £3,000 at the end of 1908. The donations to the fund in 1909 include one of £25 from the committee of the electrical engineers' ball. Grants in aid amounting to £77 were made during 1909. The Wilde Benevolent Trust Fund stands at £1,744. 16s. One grant in aid of £25 was made from the income of the fund during 1909.

Annual Accounts.—The report of the hon. treasurer, Mr. Robert Hammond, shows that the balance carried to the general fund at the end of 1909, being excess of income over expenditure, was £3,283. 3s. 11d., as compared with £3,253. 9s. 3d. for 1908. In this comparison no account is taken of outlays in connection with the acquisition of the Institution building. The balance-sheet shows that the total assets amount to £84,906. 17s. 3d., against which are to be set liabilities amounting to £29,081. 2s. 3d., leaving as the net assets of the Institution £55,825. 15s. This amount is almost entirely locked up in the acquisition of the lease of the Institution building, in the structural alterations, and in the expenses incurred prior to occupation.

In consequence of the acquisition of the lease of the Institution building, the constitution of the building fund account differs materially from that set out in preceding years. The investments have all been realised, and the fund has been augmented as follows: (*a*) Permanently, by transfer of £2,201. 8s. 7d. from the entrance fees fund, and by revenue from the Tothill-street property, subscriptions, donations, dividends, and sundry other items, £1,234. 7s. 5d.; (*b*) temporarily by loans, on mortgage from the Economic Life Assurance Society £26,000, from life compositions fund £5,613. 3s., and from general fund £5,582. 5s. 11d.

The general fund has increased to the extent of £3,283. 3s. 11d. during the past year, and now stands at £10,135. 10s. 8d.

Library.—The Council have now acquired 1,444 out of the 1,623 works which were reported to be wanting to complete the Institution's collection of electrotechnical literature. In addition to these, 67 new books have been purchased since May 20, 1909, and 220 books and pamphlets have been presented by members, publishers, and kindred societies. The total number of readers during the past 12 months was 614, of whom 39 were non-members.

An appendix to the report contains a list of transactions, proceedings, &c., received by the Institution.

THE INSTITUTION OF ELECTRICAL ENGINEERS COUNCIL ELECTION.

The following communication (in the style here shown) was recently sent to a number of members of the Institution:—

FORTHCOMING ELECTION OF MEMBERS OF COUNCIL OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

On or about the 18th inst. a Ballot Sheet will be issued by the Secretary, which will contain the following names of new nominees for election as Members of the Council:—

H. Dickinson, P. V. McMahon,
J. E. Kingsbury, R. K. Morcom,
S. L. Pearce,

who are the nominees of the Council, and also the name of Mr. H. Faraday Proctor, who has been nominated, seconded and supported respectively by Messrs:—

W. A. Chamen, Cardiff (Proposer) C. A. L. Prusmann, Swansea,
W. W. Lackie, Glasgow (Seconder), Walter J. Bache, Cheltenham,
H. Collings Bishop, Newport, R. A. Chattock, Birmingham,
Arthur Ellis, Cardiff, T. O. Callender, London,
H. D. Munro, Exeter, David E. Roberts, Cardiff,
E. G. Okell, Plymouth, Theodore Schontheil, Cardiff, and
Herbert T. Sully, Bristol, A. J. Hodgson, Chelmsford.

Mr. H. Faraday Proctor comes of the same family as the famous Michael Faraday. He is a member of the Institution of Civil Engineers as well as of this Institution, and is a Past President of the Incorporated Municipal Electrical Association, of which he was one of the Founders, and of which he is, since 1905, Honorary Secretary.

He is the Electrical Engineer to the Corporation of Bristol, which position he has held since 1892, having previous to that date been Assistant Engineer to the Newcastle-on-Tyne Electric Supply Company.

He has always taken a very active part in all legislative matters connected with Electrical Engineering, and is well known for his steady and continued application to whatever work lies before him.

The nomination is made in accordance with Section 45 of the Articles of Association. Although this power to nominate has existed for many years past, **this is the first occasion upon which there has been an Election,** because the number of nominees put forward by the Council has always been sufficient only to fill the number of vacancies, and no one outside the Council has hitherto put forward any other nomination.

The result is that many members of the Institution feel that they have no interest in the election of the Council, and there is not that universal feeling of loyalty to the Institution which is so very necessary to its continued success.

Digitized by Google

The nomination of Mr. Proctor has not been made out of any feeling of antagonism to the Council, but on account of a genuine desire to further the true interests of the Institution **by giving its members an opportunity of voting by ballot for members of Council, as is the case every year in other Institutions**, and also on account of a desire to increase the provincial representation upon the Council **and particularly to place thereon a member intimately acquainted with the West and South-Western Districts of England and South Wales**.

It is strongly felt that by putting upon the Council a man possessing Mr. H. Faraday Proctor's special qualifications for the position, and one who is able regularly to attend the Council Meetings as Mr. Proctor will be able to do, not only will the existing members in the District concerned take a greater interest in the Institution, but a considerable further number of Electrical Engineers who are at present holding aloof will be induced to join.

There is some danger in districts where the use of electricity is developing greatly, as it is particularly in South Wales, that other Institutions will take the place which should be held by the Institution of Electrical Engineers.

For these reasons your vote is asked for Mr. H. Faraday Proctor.

In order to make the votes of those who wish to put Mr. Proctor upon the Council as effective as possible, **it will be necessary for them to decide unanimously upon the name of one of the other nominees which shall be struck out**, as there will be one more name upon the ballot sheet than there are vacancies to be filled.

As provincial representation is of great importance to the well-being and wide-spread popularity of the Institution, it is suggested that the names of Mr. H. Dickinson, Mr. R. K. Morcom and Mr. S. L. Pearce should not be struck out, and of the two remaining names, although it is regretted that either should have to be struck out, it is felt that as Mr. J. E. Kingsbury has already served several times as member of Council and has been a Vice-President, it would be better to put Mr. P. V. McMahon upon the Council at the present time. Mr. McMahon has not yet served in that position, and he represents Electrical Railway Engineering, of which particular branch of the profession there is so far no member upon the Council.

While, therefore, Mr. Proctor's supporters fully appreciate the services which Mr. Kingsbury has hitherto rendered to the Institution, and do not at all wish to prevent his being returned to the Council again at some other time, they feel obliged upon this occasion to suggest that his name be struck out on the ballot sheet.

You are reminded that **all members, associate members and associates of the Institution** whose subscriptions are not more than six months in arrear **are entitled to receive ballot sheets and to vote** (See Sections 36 and 45 of the Articles of Association, which are to be found with the list of officers and members issued each year). The ballot sheet must be returned at or before the Annual General Meeting on the 26th inst.

W. A. CHAMEN,
ROYAL CHAMBERS,
PARK PLACE, CARDIFF.

May 13, 1910.

THE ELECTRIC FURNACE IN THE IRON AND STEEL INDUSTRY.*

BY G. HOOGHWINKEL.

The writer proposes in the following remarks to give an idea of the results obtained with various types of electric furnaces both for smelting and refining work. This seems all the more desirable as considerable progress is being made in other countries, although the conditions are better perhaps here than anywhere else. England, and especially Sheffield, are always held up, and with ample reason, as the home of the special steels, the most modern development of the steel industry. The use of, and the demand for these special steels is increasing every day, and it is not rash to predict that in the near future most of the steel produced will be special steel containing one or several of the rarer metals, and to a chemical and physical specification varying in each case and for each special purpose, among which steels may be mentioned high speed tool steel, steel for motor cars, and perhaps aeroplanes, steel for special castings, boiler plates, steel for railway trucks, special track work, bridge girders and rails. Nearly all these steels have been manufactured in the electric furnace in various countries, and it will not be long before no steel works will be complete without one or more electric furnaces to supply the ever-growing demand for special steels at reasonable prices, and especially to definite and stringent specifications, and of exactly the same composition for repeat orders. The last-named condition is of special importance where special steels are concerned, and it is at present exceedingly difficult to obtain, even where very high prices are being paid. The writer is at present advising on a steel refining furnace for the production of a special steel entirely free from phosphorus, as it was found impossible to obtain this particular steel of always exactly the same composition.

* Paper read before the Sheffield Society of Engineers and Metallurgists. Slightly abbreviated.

A.—By far the greatest demand, however, will arise when once the various railway authorities have settled upon a new rail for main lines, the present rails being entirely unsuitable both chemically and physically to stand the great strains to which they are submitted, by express traffic, during a reasonable period. A beginning in this direction is being made in Germany, where the State Railway authorities have issued a specification for electric steel rails specifying higher figures for the physical tests and resistance to wear than is usual for ordinary basic rails, viz., a tensile strength of 99,000 lb. per square inch against 85,000 lb. per square inch. They also require a guaranteed life of 10 years for the track rails. The actual test figures obtained with both quality of rails were 119,000 lb. and 97,000 lb. respectively. An electric steel rail, made for the Metropolitan Railway of London, and tested at the Clarence Steel Works of Dorman, Long & Co., Ltd., contained carbon 0·78, silicon 0·196, manganese 0·285, sulphur 0·035, phosphorus 0·022. By the Brinell hardness test, with a 19 mm. ball and 50 tons pressure, it gave an impression 3·7 mm. in diameter. With a 2,240 lb. drop test falling 25 ft., it gave 3·56 in. deflection; second fall of 21 ft. did not break it, but broke at the third blow with 37 ft. fall.

The following results have been obtained from some 80 lb. electric steel rails rolled in the United States, carbon content 0·80 per cent.

Weight of Tup, 2,000 *lb. Distance between Bearings*, 4 *ft.*

No. of drop.	Height of drop.	Total deflection in inches.
1	20 ft.	2·5
2	10 ft.	3·5
3	10 ft.	4·2
4	10 ft	Broken.

The same may be said of steel castings produced in the electric furnace. It has been found that the chemical, physical and machining qualities of such castings are far superior to those produced in crucibles on account of the facility and safety with which any specified quality can be produced. In short the electric furnace will be found a necessity in all large steel works for the production of high-class uniform steel for different purposes in large quantities and to various specifications at reasonable prices. This is the first and most important source of demand, and the furnace will be used more often as a refining furnace, working on hot charges direct from the converter or mixer, or from a Thomas, Martin or Bessemer furnace, or on cold scrap and pig iron. As will be shown later on, for certain classes of steel, such as fine tool steel, soft steel castings, &c., the latter method is preferable.

The writer wishes to state already at this stage that the cost of electric power enters only to a certain degree into the calculations, as it is only a small fraction of the total cost of production (about 3 per cent. to 8 per cent. for hot and cold charges respectively). It seems that this point is often misunderstood by our steel manufacturers, and that it is thought that the electric furnace is destined to be used only where very cheap electrical power is available. Even with a town supply at a price of between ½d. and 1d. per unit the production of electric steel is a commercial proposition of no uncertain merit. But in the waste gases from blast furnaces and coke ovens, a cheap supply is available for operations on a large scale, and it will be found that this is quite the most economical and profitable way of utilising these waste gases, the other power requirements at the steel works being satisfied from some other source of supply. For town supply stations, and even more for power supply companies, these electric furnaces will supply an excellent load on account of their high load-factor (50 per cent. and 75 per cent. for hot and cold charges respectively). If operations could be so arranged as not to coincide with the peak loads of the supply stations, very low prices could be charged to the advantage of both the supply companies and the steel makers. At the Niagara Falls and other power centres in the States this is actually being done.

B.—The next general use to which the electric furnace will be put is the production of steel castings both for high grade and medium grade products. The electric furnaces for these purposes will be generally of smaller capacities than those referred to before. They will replace the crucible method, to which they are much superior, owing to the absence of the expensive and short-lived crucible with its inherent disadvantages of introducing impurities into the steel. In addition, the high temperature of the cast can be utilised in manufacturing ocmplicated parts. Such castings have been made now for a considerable time in Girod, Stassano, Heroult, Kjellin, and other furnaces with complete commercial success, and they are distinguished by a very long elongation value (25 per cent., with a breaking strength of 60,000 lb. per square inch) a low percentage of sulphur (0·03 per cent.), and phosphorus (0·06 per cent.) This is of particular value for such work as railway and motor car materials, light castings for flying machines, &c. The pure Lancashire and Swedish iron formerly used in the crucible furnace for this class of work cost £10 per ton, and the casting about £15 to £20 per ton.

Digitized by Google

The cost of production of these steel castings in a 1-ton Stassano furnace at the Bonn File Works amounted to £9 per ton, including all capital charges. The reason for this difference is:—(*a*) The cheaper initial materials (scrap at 67s. per ton). (*b*) The total cost of current (at ½d. per unit), upkeep of furnace electrodes, &c., together 64s., is considerably less than the cost of crucibles, coke, wages, &c., required by the crucible furnace. Moreover, the handling of a simple pouring furnace is much easier than the separate handling of heavy and cumbersome charged crucibles. The charge of ½d. per unit for power is a fairly high one for work of this class, and electric power can be obtained nearly everywhere in England at that figure from existing electric supply undertakings. It seems, therefore, that the days of the crucible furnace are numbered, and there is no excuse for up-to-date steel works to cling to the antiquated method of the crucible furnace with all its disadvantages. It seems to the writer that this particular field is a very promising one in Sheffield, and can be approached by steel makers without any misgivings as to its commercial results, as in most of the continental plants, excellent results were obtained with untrained men.

The furnaces for this class of work should be from one to three tons capacity, and the cost of such a furnace complete varies from £750 to £1,500 for a 2-ton furnace depending on the type chosen. The requirements for a furnace of this class are different from those of the first category. The small charges required, the desirable simplicity and safety in handling by the existing non-electrical staff, the necessity of using power from existing power supply undertakings are all conditions which do not have the same importance in large installations of the first-mentioned class. A 1-ton Stassano furnace will require about 200 kw. on an average during the four hours the power is required, using about 800 units per ton of steel produced.

There are now quite 60 electric furnaces of this class at work in various countries, and there is no excuse whatever for our backwardness, at least in this particular branch of electric smelting. The production of steel castings by means of the electric furnace has been a commercial success from the very beginning, and the castings produced have been of a better quality in all respects. The plea one so often hears of "novelties which have not yet stood the test of commercial application" can in this case be answered with a list of works where castings are produced in an electric furnace at a price far below that of the products of the crucible furnace. One or more electric furnaces of this type should be installed in every iron and steel works with a pretence of up-to-dateness, and if those responsible for the commercial management of these works would call in the help of the electrician, it would be seen that first cost is in this case not such an insurmountable obstacle as it seems with most improvements with us. Not only in iron and steel works, but also in such works as naval and shipyards, locomotive and carriage works, bridge building works, machine shops, electrical works, &c., small electric furnaces producing steel for castings should be indispensable. The very materials used, such as scrap, trimmings, stampings, punchings, steel and iron borings, &c., which are always produced at such works, point to the utility of such furnaces not only as refuse destructors, but as the means for producing their own castings at a very low price, thereby making them independent of the foundries, and giving them better facilities for regulating their deliveries in accordance with modern demands for promptness.

The electrical furnace will also replace the small converter which is now often used with or instead of the open hearth furnace, *e.g.*, in shipyards. Such a converter as a rule produces a quantity in excess of the requirements, so as to prevent the converter from cooling off. The electric furnace is a combination of the cupola furnace and the small converter, and produces a superior material (less sulphur and phosphorus) from an inferior charge (60s. instead of 90s. for special pig) in smaller quantities, at a lower cost.

A further product to be made in the small electric furnace is malleable cast iron, which is now made in the cupola furnace, the crucible, the small converter and the reverberatory furnaces at higher cost, at least for small quantities (on account of high fuel charges and expensive special pig iron used). It will be necessary, however, to convince the managers of the works referred to that the two supposed bugbears, *i.e.*, heavy maintenance of the furnace and linings and heavy consumption of electrodes, are in reality quite unimportant, at least in some of the better known furnaces. A few figures taken from actual practice with furnaces producing the class of products under discussion will be given at the end of this chapter to illustrate these two points.

In fixing on a particular type of furnace it must be remembered that the initial charge to be used will be cold, contrary in most cases to the process followed with furnaces under class A. A resistance furnace, or better still, a combination furnace, will fulfil the requirements, but all the Héroult, Stassano, Girod and Rodenhauser furnaces have given excellent results for this class of work. Fairly pure materials will always be used, and if no refining but only smelting and "killing" is required, using very pure materials, a plain induction furnace such as the Kjellin will give an ideal crucible steel, as the furnaces of this class will not exceed two tons as a rule. With impure materials, where refining is required, the plain induction furnace is impracticable on account of its inherent electrical disadvantages and the difficulties of obtaining a hot and fairly liquid slag, and handling it. Another type which combines the advantages of the pure resistance furnace (easy handling and regulation) with those of the arc type furnace (adaptability to existing public supply and to all initial materials and products) is the Grönwall furnace, which uses two-phase current in two vertical electrodes, the common return or neutral being through the bottom lining of the furnace. This furnace is extremely simple in construction and requires no rotary movement on account of the vertical and horizontal effect of the two phases. The lining maintenance is very small, the latter only consisting of a rammed mixture of dolomite, or magnesite and tar. The hottest part is also in the slag, as in the other types of arc furnaces, so that refining can be carried on until the desired result is obtained. The conditions which must be satisfied by a furnace for the practical purpose under discussion are:—(*a*) Good thermal efficiency and high power-factor combined with medium output. (*b*) Easy and simple handling, regulation and repairs. (*c*) Adaptability to all kinds of initial materials, hot or cold. (*d*) Must be capable of working with an ordinary three-phase supply, and have a fairly constant energy consumption. (*e*) Must admit of using low voltage at the furnace. (*f*) Must admit of easy refining with a basic slag, even with impure materials high in sulphur and phosphorus contents. (*g*) The bath of molten metal must be homogeneous throughout, even after the refining process has been completed.

There is no type of furnace which unites all the above conditions in the same degree, and in the choice of a suitable furnace one must therefore be guided by local conditions and requirements, and it is here that the expert will have to decide and guide the decision of the works manager.

Without in the least attempting to advocate the use of any par-

---

Cost of Production and Repairs in Various Furnaces of Similar Output Obtained from Actual Practice in the Production of Steel Castings.

Girod Furnace at Ugine, 2 tons.

Charge: Cold scrap, turnings and some cast iron and iron ore.
Total time required: Rated at 275 kw., 5 hours per ton of steel.

Lining repairs: (dolomite or magnesite paste)	£0	6	0	per ton
Electrodes consumption: (40 lb. ordinary retort carbon)	0	4	0	„
Energy consumption: (850 kw. hours plus 10 per cent. loss, say 960 units at ½d. per unit)	2	0	0	„
Wages (2 men)	0	4	9	„
Materials charged, say, 1 ton scrap	3	0	0	„
2 cwt. lime, 2 cwt. iron ore, ferro alloys, hammer scale	0	3	6	„
Upkeep of furnace, wear and tear of plant, ladles, &c.	0	12	0	„
Depreciation	0	1	6	„
	£6	11	9	„

Cost of furnace plant complete without power plant, £1,000. In case molten steel from a Bessemer converter, Martin or open hearth furnace is charged into the furnaces, the energy consumption and cost is reduced to one-third of the values given.

Stassano Furnace at the Bonn File Works (replacing 32 crucible furnaces *of* 6 crucibles, each of 75 lb. capacity).

Rating: 185 kw. Charge: Cold. Soft scrap, &c. Smelting period: 3½ hours. Refining period: 1 hour. Total time: 4½ hours. Daily production of cast steel, 3 tons.

Energy consumption per ton of steel, 909 units at ½d.....	1	18	0
Electrodes consumption	0	2	6
Repairs to lining (£20 per lining, 33 charges)	0	11	0
Wages (3 men)	0	8	8
Cooling water (440 gallons per ton)	0	0	5
Upkeep of furnace, wear and tear of plant	0	10	0
Materials: 1 ton scrap.....	3	7	0
44 lb. hammer scale, at 17s. per ton	0	0	4
44 lb. lime, at 12s. per ton	0	0	3
17½ lb. ferro-silicon (12 per cent.), at 150s. ...	0	1	2
9 lb. ferro-manganese (80 per cent.), at 220s.	0	0	11
1½ lb. aluminium	0	1	2
Depreciation, 10 per cent.	0	4	2
Duration, 5 hours..... Total.....	£7	5	7

This means per ton of finished castings 1·5 tons of molten steel, less 0·5 ton of scrap, say, 180s., £9.
Cost of furnace complete, £1,500.
The lining lasted an average of 70 charges.

Digitized by Google

Kjellin Furnace at Gysinge.

1½ tons charge of cold pig iron, very pure iron ore, briquetted. Rating, 175 kw. Single-phase, 15 periods, 500 volts, P.F., 0·7. Produced crucible quality steel.

Cost per ton of steel (melting only) :—			
Energy consumption, 809 units, at ½d. (water power)...	£0	7	10
Repairs to lining	0	3	5
General expenses	0	5	7
Wages	0	7	3
Cost of casting	0	4	6
Materials : 1 ton of scrap, at 80s.	4	0	0
Flux	0	2	1
	£5	10	8

The low figure is, of course, due to the low charges for power. Interest and depreciation are also not included.

Rodenhauser Furnace at Volklingen, 2 tons Capacity.

Rating : three phase, 350 kw., 500 volts, 50 periods, 0·8 P.F. Refining only : Charge, hot from basic Bessemer convertors containing 0·08 per cent. phosphorus and 0·1 per cent. sulphur. Product : Crucible steel for castings.

Energy consumption, 390 units at 1·09d.	£1	7	0
Heating up	0	1	2
Repairs to lining (10 days, or 160 tons per lining)	0	1	6
Other repairs	0	0	10
Wages	0	2	0
Materials : 1 ton liquid steel	3	9	0
Mill scale, lime, ferro-silicon	0	4	5
Interest and depreciation (15 per cent.).....	0	1	5
	£5	7	4

Cost of complete furnace, £2,700. The cost of power per unit in this case was, of course, very high.

Héroult Furnace at La Praz, 2½ tons.

Rating : 370 kw., single phase. Charge : cold scrap. Product : crucible steel.

ticular make of furnace, the writer wishes to enumerate the particular conditions which in each type of furnace have proved to be more especially fulfilled. The conditions sub. (*a*) are better complied with the by Héroult, Girod, Grönwall and Rodenhauser furnaces than by others. Condition (*b*) is better satisfied by the Grönwall, Kjellin and Rodenhauser furnaces. Condition (*c*) by the Héroult, Girod, Stassano, Grönwall and Rodenhauser furnaces. Condition (*d*) by the Stassano, Grönwall and Rochling-Rodenhauser furnaces, and, as far as the latter condition, also the Girod furnace. Condition (*e*) by the Girod, Stassano, Grönwall and Héroult furnaces. Condition (*f*) by the Girod, Stassano, Rochling-Rodenhauser and Héroult furnaces. Condition (*g*) by the Rodenhauser, Kjellin, Frick and Grönwall furnaces.

It may be stated generally that all the furnaces using vertical electrodes through the roof of the furnace offer the disadvantages of heavier repairs to the roof lining, due to the unequal heating, and that all furnaces using electrodes have the disadvantage of heavy energy losses (over 10 per cent.) in the electrodes. One of the future modifications will certainly be in the direction of metal electrodes used at an angle of 45 deg. There are several modifications of each of these parent furnaces, but they do not offer material differences in construction, and their advantages and disadvantages are more or less the same as those of the typical furnaces from which they are evolved. Among the simple induction furnaces may be named the Frick furnace (differing only from the Kjellin furnace in the position of the coils), Colby, Hiorth and Schneider furnaces.

The resistance furnaces of the Héroult type, apart from the Girod type, are represented by the Kjellin, du Giffre, Gin and Anderson furnaces. The plain arc furnace is principally represented by the Stassano furnace. In selecting a suitable type of furnace plant in accordance with local requirements, the only guide is, of course, the expert's advice, or to await the results obtained elsewhere. The last practice, in many branches of our industries, has become something of a mania, in strong contrast to the former leading attitude of our manufacturers, and the writer would strongly plead a return to earlier methods.

C.—The third purpose for which electric furnaces should be installed is for the manufacturing of special steels, ferro-alloys, &c. Foundries, for instance, should be each provided with a 200 H.P. or 1 ton furnace to utilise their waste materials in the production of high-priced tool steel. Such works, which require expensive and homogeneous steel for special tools, razors, &c., could easily make or refine their own steel from cheap materials and thereby annually saving amounts entirely out of proportion with the first cost of one or two furnaces, and thus making themselves independent of the steel works, which, on the other hand, are not anxious for small orders of special steels. Other examples may be found in ordnance and similar works, where the broken and rejected shells can be re-smelted and turned into new ones.

Carbon steel for chisels, blades, files, extra hard steels for lathe tools, including such varieties as nickel, chrome, chrome-nickel, tungsten and other alloy steels, also case-hardened steels, will be more and more produced in the electric furnace on account of the absence of the action of the air, which permits of the production of steel without the usual overdose of manganese and silicon, and with a hard surface. A steel for shafts, gearing and springs is being produced at present at Turin in the electric furnace to the following specification :—

—	Elastic limit. tons per	Max. stress. sq. in.	Elongation. %	Contraction %	Resilience. kg.
(A) Annealed at 900°C.	41·9	50·8	18	29	14
Hardened at 800°C. and tempered at 450°C. ..	67·9	76·2	8	32	12
(B) Annealed at 900°C.	41·3	58·4	15	25	11
Hardened at 800°C. and tempered at 450°C. ...	82·5	96·5	6·5	32	6
Nickel steel (5% nickel)—					
Annealed at 900°C.	47·9	49·2	15·5	36	10
Hardened at 800°C. and tempered at 600°C.	59·7	66	9	43	13·5

There are a great many other applications of the electrical furnace for such special purposes which are suggesting themselves every day, but enough has been indicated to give an idea of the extent of these applications. The type of furnace to be used is practically the same as the types indicated under B, but generally of a smaller output, 1 to 1½ tons being a maximum. Here again simplicity in handling is the principal requirement, and the furnace must be easily adaptable to existing sources of electric supply. The cost of such a furnace will not be high, so that it seems that nothing stands in the way of a growing demand for electrical furnaces of small sizes for special work. It may be interesting to give a few results from furnaces actually in commission for this class of work, giving some figures as to cost, &c.

D.—The fourth class of electric furnace consists of the furnaces used for the reduction of iron ores. This type of furnace may be said to be more or less in the process of development, but several furnaces are at work, although the results have not been uniform. This is, of course, due to the composition of the various ores used, and therefore only some general points will be dealt with in this Paper, especially as our home industry is not so much concerned with this furnace at present, although with the rising prices of coal, and coke which are foreshadowed, the smelting of iron ores by means of electricity generated from coal even at home will become a possibility. At present, however, such countries which possess large deposits of iron ore and little coal, such as Mexico, Brazil, Canada, India, South Africa, Spain, &c., but which have ample water power, will derive immense benefits from the electrical furnace.

There are at present two different methods to be considered. The first is practically a small blast furnace combined with electric heating, and the second utilises the refining furnaces of the Stassano and Héroult type. In the latter case steel is produced directly from the ores, but the ores must be very pure and the proportion of carbon and fluxes must be carefully adjusted. The ores used at Turin at the Stassano furnace consisted of finely ground hematite mixed with a limited quantity of carbon and flux, and moulded into briquettes.

For impure ores, magnetite, &c., which are generally found in large quantities in the countries which possess little or no coal, it is more likely that a furnace of the blast furnace type will be selected. These ores are sometimes high in sulphur but free from manganese. In other cases titanium is present. The first experiments with such a furnace were made in Sweden at the Domnarfet Iron Works, and excellent results have already been obtained.

Taking an average for several casts, the production was found to be 2·44 tons of pig iron per electrical horse-power year, with a consumption of 5 kg. of electrodes per ton of pig iron produced. The cost per ton of pig iron was 35s. 8d., taking power at 50s. per electrical horse-power per year. A source of trouble was the accumulation of carbon in the smelting chamber, which had to be removed by discontinuing the gas supply through the tuyeres.

It may be taken for granted from the above experiments that with ore of over 60 per cent. iron in a 2,500 H.P. furnace, 3 tons per electrical horse-power per year may be counted upon.

The Paper concludes with a list of furnaces in operation.

THE GLASGOW MAIN DRAINAGE AND SEWAGE DISPOSAL WORKS.

Summary.—An account is given of the electrical features included in the immense drainage scheme recently laid down by the Glasgow Corporation. Among the features of interest are electric pumping, an electricity supply station and special electrical plant for clearing the catchpit.

The third and last section of this important scheme was formally opened on May 2nd by Lord Provost McInnes Shaw.

The whole scheme, next to that of the London County Council, is the largest of its kind in the world, and there are many features of novelty about the gear for handling the sewage of the large communities embraced in the scheme. The whole aim of the promoters, the Glasgow Corporation, has been the prevention of the discharge into the river Clyde of the sewage of the city. Since the opening of the first two sections there has been a marked diminution in the intensity of the effluvia given off by the river in the warmer months of the year. The area at present embraced covers 41½ sq. miles, and includes the whole of the city of Glasgow, with the burghs of Rutherglen, Govan, Pollokshaws, Partick, Renfrew, Clydebank and the intervening portions under the county authorities of Lanarkshire, Renfrewshire and Dumbartonshire. Negotiations are at present proceeding to prevent the discharge of free sewage into the river higher up, as at Hamilton, &c., and also into the tributaries of the rivers Kelvin and Cart, the first of which flows into the Clyde inside the city boundaries and the latter a little below the boundary. The river Clyde, which has been deepened and straightened considerably during the last 60 years by the Clyde Navigation Trustees at enormous expense, is now subject to the tides, and is deep enough to permit of the largest steamers entering the Glasgow Harbour. The necessity, therefore, of preventing the Burghs of Paisley, &c., lower down the river discharging sewage without treatment is apparent.

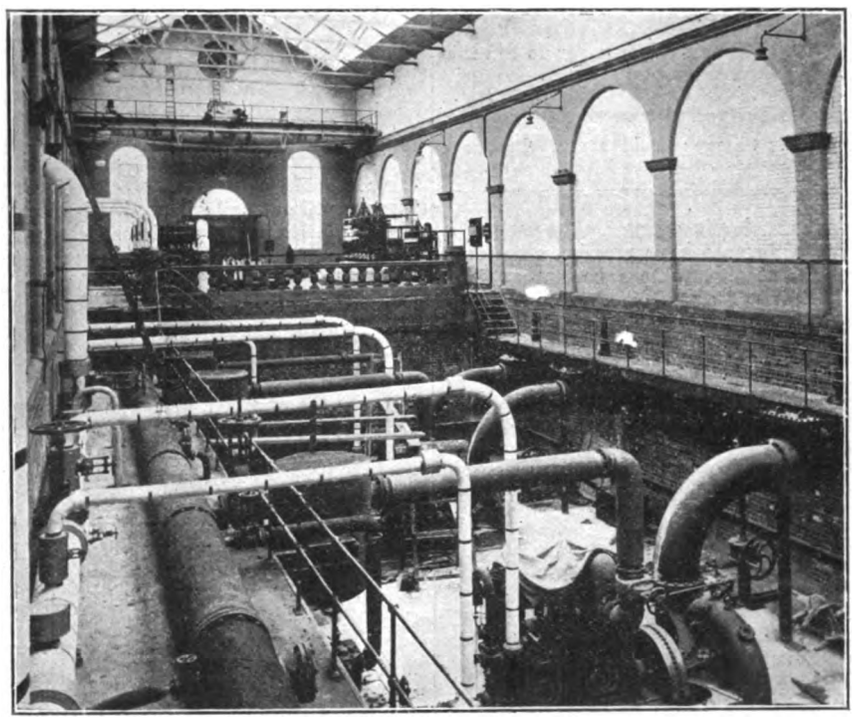

Fig. 1.—Interior View of Main Engine Room.

The first steps taken were to obtain Parliamentary sanction for the first section, that at Dalmarnock, embracing 11 sq. miles, in 1891. Subsequent additional powers were obtained between the years 1896 and 1907, and the section embracing the whole of the north side of the river, amounting to 15 sq. miles, with works at Dalmuir, 7 miles down the river from Glasgow, was opened in 1902. The last section, with works at Shieldhall, opened last month, embraces, as indicated, the remaining area on the south side of the river, covering 15½ sq. miles.

The amount of sewage and proportion of rainfall drained from the area is estimated at 250,000,000 gallons per day. For its collection some 30 miles of new sewers had to be constructed. These sewers vary in size from 2 ft. 6 in. to 10 ft. in diameter, which is the size of the main sewers entering the respective works. The gradients vary from 1 in 25 to 1 in 2,800. Their depth varies from 4 ft. above ground to 60 ft. below the surface, and they pass under railway lines no fewer than 30 times.

The main feature on the northern side was getting across the river Kelvin, and for this purpose a pumping station was put down alongside that river, thus giving the sewage a lift of 37 ft. 6 in. on the west side, whence it gravitates to the works at Dalmuir.

On the south side, due no doubt to the comparative flatness of the original country, pumping into the main sewer had also to be resorted to, and a pumping station for this purpose was put down at Kinning Park. This latter gives a lift to the sewage of 28 ft., and forces it a further 17 ft. into the main sewer, whence it gravitates to Shieldhall, 3 miles off.

Neither of these pumping stations presents anything of interest to electrical engineers, the pumps being of the steam-driven reciprocating engine type.

The sewage from Govan and Renfrew and district is pumped at the Shieldhall works by three centrifugal pumps, and is given a lift of 21 ft. to bring it to the level of the Glasgow sewage. Entering the works at Shieldhall, which lies between the river and the main road between Glasgow and Renfrew, one is struck with the enormous volume of sewage to be dealt with. On the right are the main offices and on the left are the lime agitators and precipitation tanks, while in front are the main station and treating house. The whole works are self-contained — that is, electricity at 250 volts is generated on the spot and everything is electrically driven. Another feature that strikes one is that there are no belt drives, except for the tools in the mechanics' shop.

The lime agitators referred to are three in number, and are for the purpose of keeping the lime mixture in a condition ready to be discharged into the sewage as it enters the catchpit referred to later.

For this agitating process the mixture passes into three brickwork tanks, each measuring 100 ft. by 30 ft. by 5½ ft. deep. Along each side of each tank there are gantry rails, and on these rails runs back and forward, automatically reversing at each end, a specially made four-wheeled stirring arrangement, which in travelling keeps the lime liquid in a creamy condition, it being necessary to discharge a saturated solution into the wage at the catchpit.

These travelling stirrers are driven by endless steel ropes fixed to the screens permanently, but passing over drums which are automatically reversed. These drums, of which there are three to each stirrer, are in turn driven by a 15 H.P. Rees-Parker Roturbo motor, one motor to each stirrer, through speed-reduction gear and reversing clutches on the drum shaft.

The lime mixture is conducted along concrete-lined ducts, and there are suitable penstocks controlled by small motors.

Passing on, we enter the mechanics' shop, where are the usual machine tools for repair work and an overhead 8-ton hand-operated travelling crane. There are here two 10 H.P. and one 5 H.P. motors. Next door is the boiler house, containing three Babcock & Wilcox chain-grate mechanically-stoked boilers, and an ash hoist driven by a 30 H.P. motor on to a line of shafting, and one stand-by Weir feed pump, a Claycross economiser, driven by a 5 H.P. motor, and a large fresh-water storage tank.

Digitized by Google

Adjacent to the boiler house is the main engine room, as shown in Fig. 1. Here are three Crompton-Howden 150 kw. steam sets generating at 255 volts, the generators being of shunt-wound direct-current type. The main and feeder distribution switchboards by Lowdon Bros. are fitted with Whipp & Bourne double-pole circuit-breakers, Ferguson switches, Everett, Edgcumbe instruments and Reyrolle fuses, mounted on enamelled slate and of the usual construction. There are also an 8-ton hand-operated overhead travelling crane, two Mirrlees-Watson condensers, using the treated solution, by the way, for condensing purposes, and two air pumps.

The pumps for the Govan and Renfrew sewage referred to above are also in this room. They are of Drysdale's make, centrifugal type, driven by Howden engines. There is one 24 in. diameter for dealing with 600,000 gallons per hour, one 18 in. diameter dealing with 330,000 gallons, one 15 in. for 240,000 gallons and two 10 in. diameter. The sewage entering these is controlled through hand-operated penstocks.

Alongside the engine and boiler house is the men's messing and other accommodation fitted up in the usual manner.

Passing through the engine room we come to the iron liquor stores and tanks. These tanks are of special construction, being lined with oak, then a section of puddle, and another lining of oak, to prevent leakage and at the same time to stand the liquor's chemical action. These tanks being built in the ground necessitates the liquor being pumped into the catchpit. This is effected by a double ram suction pump by Brackett, of Colchester, driven by a 3 H.P. motor, direct coupled, situated in the adjoining oxidiser house. In this house are also the three oxidsier drums, as they are termed. The iron liquor, like the lime mixture, must be a saturated solution, and to keep it so and prevent settling or precipitation these revolving drums are necessary. The drums are each 11½ ft. long and 8 ft. diameter, and are constructed entirely of oak. The axles are also of oak and revolve on rollers. The drums are geared to a shaft which in turn is driven by either of two 30 H.P. motors through a suitable clutch gear. From the drums the liquor gravitates to the catchpit.

Adjoining is the lime store, capable of storing 1,000 tons of lime. In this store are also the four pan mixers for slaking the lime and making the mixture. They work in pairs, and are all driven by a 30 H.P. motor geared to a shaft with clutches for each pair of pan mixers. From here the lime mixture goes to the agitation tanks and back to the catchpit, which is in the house adjoining the lime store.

This catchpit is 170 ft. long, 17 ft. deep and 16 ft. wide, tapering down to a depth of about 18 in. at the bottom. A part of it is seen in Fig. 3. Along each side are standard rails on which runs a unique piece of gear of special construction and the first of its kind. It is to the design of Mr. W. D. Hamilton, the consulting engineer. At Dalmuir a man is required to sit on the travelling carriage, but as this means sitting over the open sewer all the time during a shift, the disadvantage of such an arrangement was obvious, hence this development.

As indicated in the photograph, it consists of a four-wheeled bogie carrying a bucket dredger and elevator. The sewage on entering the catchpit meets the lime mixture, which causes the solid matter to precipitate and settle at the bottom of the sloping-sided catchpit. This, therefore, requires constant clearing, obtained by the use of this special dredger. The dredger is self-contained, and after starting requires no attention. It automatically reverses itself at each end of its travel, in moving along the catchpit rails, by means of the kick lever (seen projecting downwards in line with the wheels) striking a buffer fitted at each end of the catchpit. This reverses the clutch reversing gear on the opposite side of the carriage.

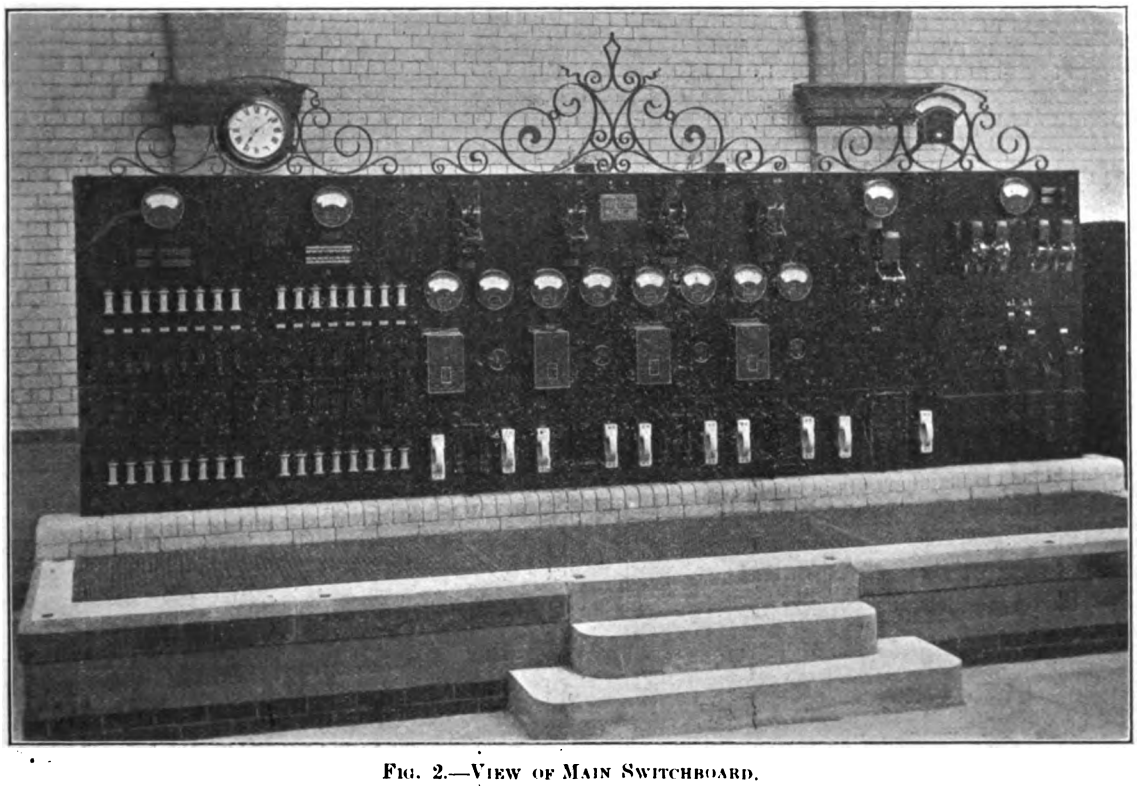

FIG. 2.—VIEW OF MAIN SWITCHBOARD.

The bucket conveyor at the same time continues elevating the solid matter and empties it through a shoot into a truck following up behind. These trucks or waggons are specially made and used for this purpose alone. They are coupled up as usual in railway practice, and move back and forth with the dredger. Being for standard gauge they are despatched all over the country with the sludge for agricultural use, but the solids obtained are used principally by the Corporation themselves on their sewage farms. Some of it is used and sold in cakes as a celebrated fertiliser.

The whole dredger, carriage and elevator is driven by a 30 H.P. motor fixed on to the carriage as seen. Current is collected in the usual way through a trolley and three wires. The starter for the motor is fixed to the back of the engine room wall, and the motor is a shunt-wound machine; hence the reason for the three wires seen in the view.

Having dropped most of the solid matter in its passage along the catchpit, the sewage is now attacked by the iron liquor,

Digitized by Google

which enters at the end remote from the lime end. This liquor is made to spray over the sewage by means of a baffle plate.

The sewage then passes through a screening plant seen behind, and in the corner of, Fig. 3. These screens are to remove any solids unaffected by the lime. They accumulate at the screens and are removed by a stationary elevator, seen at the back in Fig. 3, and discharged through a shoot into a truck standing below.

These screens are of three different meshes, and can be removed for cleaning purposes periodically like ordinary sluices. For the hoisting of the screens on to the floor level, seen in Fig. 3, motor equipments are fitted aloft (*see* Fig. 4). Each of the grids or screens is fixed to a wire rope, which passes round a revolving drum, which in turn is made to revolve through a friction clutch. The motors driving these are of 5 H.P. and of the Rees Parker shunt-wound type. This equipment stands on a raised gallery about 15 ft. above floor level. Speed reduction is obtained through worm and pinion in an oil bath.

On this gallery are also the hand wheels operating sluices to close any screen opening when necessary.

After screening, the sewage and treated liquor passes on into the open air, and, by means of suitable brickwork channels, is led into the precipitation tanks of brickwork, 15 in number, and each measuring 400 ft. by 60 ft. wide and normally holding a depth of 8 ft. of treated sewage.

Here it is allowed to rest for a time to allow the iron liquor to purify it, after which it is pumped into two iron sludge tanks, each 115 ft. by 45 ft. by 10 ft. deep. The pumps are three in number, 9 in. diameter and of Drysdale's centrifugal type, each driven by a 20 H.P. motor. The clear liquor passes off into the river and the sludge passes through pipes 18 in. in diameter on to the specially built Corporation steam hopper barge t.s.s. "Shieldhall," by which it is taken out to the open sea and there dropped. It is said that the purified liquor thus discharged into the river can be drunk by human beings without any ill effects; in any case it is used for condensation purposes.

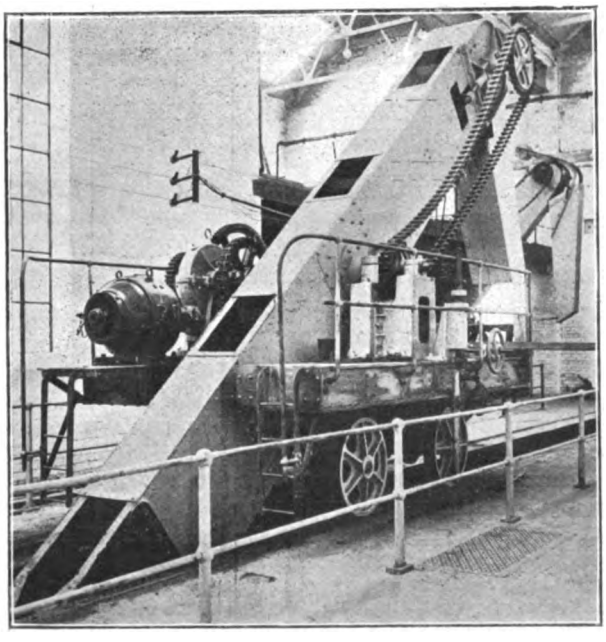

FIG. 3.—CATCHPIT DREDGER.

With the exception of the economiser and oxidiser house motors, by Wright & Wood, all the motors—some 40 in number—are of Rees-Parker make, of Wolverhampton. The starting panels, two of which are indistinctly seen in background of view Fig. 4, are by Hamilton Bros., Glasgow.

The principal engineering contractors and electricians were Lowdon Bros., of Dundee and Glasgow. Sub-contractors:—

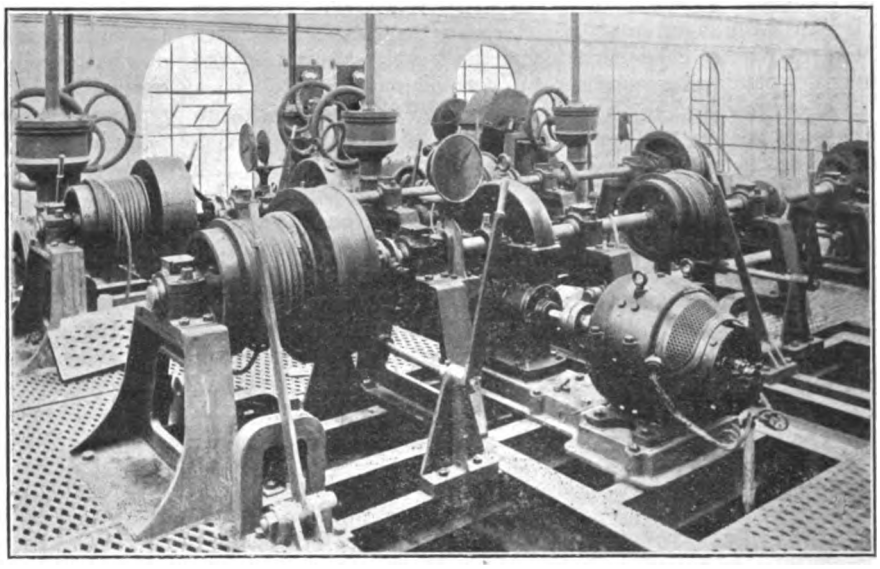

FIG. 4.—SCREENING PLANT MOTOR EQUIPMENT.

For structural ironwork of the lime agitators, mixers, &c., Barrowfield Iron Works (Ltd.), Glasgow; valves and penstocks, Glenfield & Kennedy (Ltd.), Kilmarnock; Arc Lamps in the engine room and precipitation tanks, &c., Gilbert Arc Lamp Co.

The general scheme is due to Mr. A. B. McDonald, city engineer.

The machinery buildings (sub and super-structure), sludge tanks and pump house and discharging gear, sewage disposal and treatment machinery, mechanical and electrical power and lighting plant arrangements are to the design and specification of and have been carried out under the supervision of Mr. Wm. D. Hamilton, of Glasgow, to whom we are indebted for many details.

The whole scheme, it is anticipated, involves an expenditure of £2,250,000, equivalent to an assessment rate of 7d. in the £1, but it is not anticipated that this maximum will ever be levied.

STANDARDISATION OF FUSES.*

BY H. W. KEFFORD.

(*Concluded from page 268.*)

Summary.—After pointing out the desirability of standardisation, the author gives particulars of tests on a number of representative types of fuses up to a capacity of 50 amperes, and discusses the ratio between the rated current and the normal fusing current. He then considers the general regulations for the construction and operation of standard fuses and describes a non-interchangeable fuse system. He refers to the testing of fuses, and finally puts forward some suggestions as the basis of a specification for standard fuses.

General Regulations for Construction and Operation.—While it is not desirable to specify too rigidly the constructional details to be embodied in standard fuses, yet it appears imperative that a few general principles should be laid down for the guidance of manufacturers, and one or two essential features should be demanded. As an example of the extreme necessity of this, it may be mentioned that in fuses T_5 and T_6 the fuse wire is *soldered* at each end into a small terminal plate. The distribution of the masses of metal is such that all the fuses of this type which were tested opened the circuit by melting the soldered connection; had the full rated pressure of over 500 volts been maintained, the arc, consequent

* Abstract of a Paper read before the Birmingham local section of the Institution of Electrical Engineers.

Digitized by Google

on the separation of the wire from its terminal plate, would have spread speedily and consumed the entire fuse fitting and terminals until the circuit was broken elsewhere. In a second line of fuses (R) of the totally enclosed or cartridge type, also rated for over 500 volts maximum pressure, a solid single link of soft fusible metal is used, containing a volume of metal nearly 15 times as great as that contained in another make of cartridge fuse of the same rating. This protective device is completed as an explosive of a most dangerous kind by the provision of a number of vent holes in the metal cap at each end.

If any efforts to increase the efficiency and serviceableness of fuses are to be successful it is inevitable that bare wire fuses should be abandoned; and the logical consequence of the standardisation of small capacity fuses is the introduction of a simple method by means of which the control of the fuse capacity on any circuit is placed in the hands of competent persons only. This requirement of non-interchangeability is far-reaching in its effect on fuse design, since it involves the abolition of all fuse fittings having two exposed terminals, and in so doing leads half-way to the requirement dictated by safety—namely, that no terminals whatever should be exposed on fuse fittings intended for use in private houses or public situations.

An ideal system for safeguarding a circuit against over fusing should consist of some small separate part or adjustment which can be suitably set by an electrician either to restrict the capacity of the fitting to the present current or so as to allow a definite margin for increasing the size of fuse consistent with the dimensions of the wiring or apparatus. Although it is admitted that no non-interchangeable system will do away with the deliberate over fusing of the circuits, yet sufficient will have been attained if accidental over fusing is made impossible and an obstacle is placed in the way of using hair-pins and similar well-known substitutes for the legitimate article.

In order that the idea of non-interchangeability may be fully grasped, reference may be made in detail to what is, so far as the author knows, the only type of fool-proof fuse on the market. The loose pieces or "gauge-rings" B, B¹ (Fig. 5) consist of a steatite ring

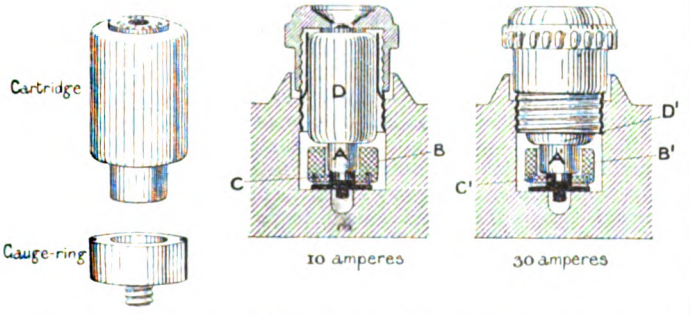

Fig. 5.—Example of Non-interchangeable Fuse System.

of constant external diameter, but having the diameter of the hole varying with the rated current. One of the terminals with which the cartridges D, D¹ make contact is situated at the bottom of the cylindrical hole in the steatite ring, and unless the stud A, A¹ is of equal diameter or smaller than this cylindrical hole, contact cannot be made. Thus B and D are gauge ring and cartridge for 10 amperes, whilst B¹ and D¹ are the corresponding parts for 30 amperes rated current. The rings B for all capacities screw interchangeably into the same terminal block, but it is evident that a cartridge, D¹, for 30 amperes will not make contact through its stud A¹ with the terminal C which lies at the bottom of a ring, B, for 10 amperes. It is, in fact, impossible to insert D¹ in a fuse fitting containing a gauge ring, B, of smaller capacity. Needless to say, each rated current has its own special diameter of stud and gauge-ring orifice.

Bare wire fuses, or rather fuse fittings, in which a conductor can be easily inserted by the user, are incompatible with protection against overloading. Two other objections of equal weight against exposed fuse wire are their liability to scatter molten or hot metal and the rapidity of corrosion unless certain non-active metals are used. The first objection holds good of all metals, but more particularly of low melting point metals, of which a larger volume is requred than if copper or silver were employed. The second objection is especially applicable to copper, which in many other respects is an excellent fusible metal.

If, on the other hand, we examine the case for fuses of the totally enclosed type, we have the following outstanding advantages: (1) The fuse wire is less liable to corrode or become injured, and therefore enclosed fuses lend themselves to exact calibration. (2) Tampering with the fuse wire is difficult, and a system of non-interchangeability is greatly facilitated. (3) If properly designed, no molten or hot matter can be thrown about. (4) Perfect operation can be obtained on heavy overloads at full voltage. (5) Less metal is required, and the weight and size of the complete fuse fitting is reduced.

The principal objections raised against enclosed fuses are mainly questions of cost, the impossibility of inspecting the fuse wire, and the difficulty of ascertaining with certainty when the fuse has blown. The first-named objection appears to be almost wholly fictitious if account is taken of the frequency with which not only the fuse wire of an open fuse is melted, but the holder itself is either cracked or so fused as to be useless. Engineers do not seem fully to recognise how much more severe in many cases is the effect of fusion produced by a heavy gradual overload at full voltage as compared with the effect of a severe sudden short-circuit. Fuses of the china holder type are often reduced to a useless condition by an overload, whereas they may withstand repeated short-circuits of a severe character without great damage. The asbestos protection now largely used, although fairly efficient when new, soon loses its efficacy after repeated blowing of the fuse, and is, moreover, frequently discarded altogether.

With regard to the deficiency of enclosed type fuses in not permitting inspection of the fuse wire or giving reliable indication of fusion, the latter is a mechanical detail which can be quite satisfactorily solved, as is shown by the arrangement adopted in a new type of enclosed fuse recently put on the market. Fig. 6 shows the design of indicator referred to. The diagrams are self-explanatory.

The demand for exposure of the fuse wire has arisen from the custom of inspecting a fuse, say of copper, either for the purpose of seeing what progress oxidation has made or to determine by its red glow or otherwise whether it was being unduly overloaded. The

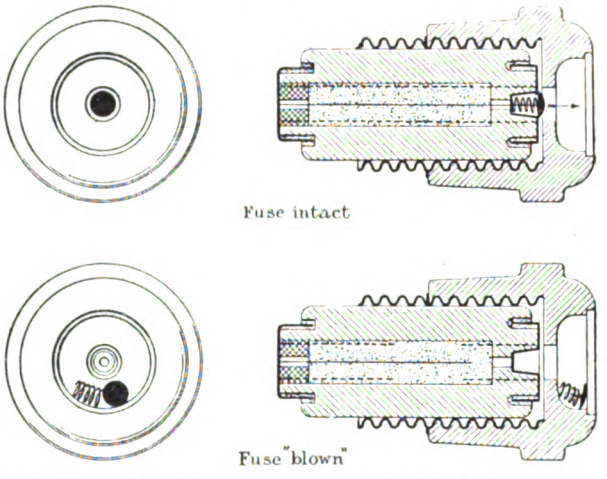

Fig. 6.—Example of Cartridge Fuse with "Self-testing" Indicator.

oxidation of a fuse is, as we have seen, harmful and unnecessary, and the rating and design of standard fuses should be directed towards minimising its occurrence; similarly a well-considered and consistent rating will in time enable the user to become familiar with the overload capabilities of a fuse of certain capacity. For fuses of the capacity under discussion a completely enclosed design is the only one which enables any set of standards to be followed or enforced with reasonable success.

Stress may be laid on four points essential to the satisfactory operation of any fuse, whether of the open-wire, tubular or totally-enclosed type; these are: (1) The volume of fusible metal should be reduced to the minimum compatible with correct rating and moderate temperature rise. (2) The fusible metal should be subdivided so that the ratio of exposed surface to cross-section does not fall below a figure depending on the design. (3) The provision of cooling arrangements adequate to extinguish the arc formed on overload. (4) In exposed wire fuses the provision of sufficiently free expansion space to prevent explosion when a short-circuit occurs. In enclosed fuses the same end must be attained by precisely opposite means, and no opening or weakness of any kind is permissible in the enclosing case.

It is interesting to notice how the fulfilment of requirement (2) naturally leads to the cartridge design of fuse, since only in this design can the proper subdivision of the fuse wire be guaranteed. The effect of neglecting proper subdivision as well as the use of too much metal is shown by photographs reproduced in the Paper. It is unfortunate that instead of attacking the problem of an enclosed fuse in an appropriate manner, some designers have considered that the simple enclosure of an open-type fuse would produce the desired end. The use of soft metals, such as tin, lead or zinc, is to be deprecated, although with very careful design successful use may be made of the non-arcing property of the last-named metal.

Digitized by Google

When a filling powder is adopted it is important that the fuse wire and filling should be free from any mutual chemical action, even when subjected for a long time to alternate heating and cooling. Fillings containing a capsule of liquid, or any hygroscopic or moist substance, are bad in principle, and may be the cause of violent explosion or of chemical corrosion of the fuse wire. Tests carried out on a very large number of filling materials lead to the conclusion that the most suitable for use in enclosed fuses are thoroughly dry uniform powders of completely inert substance.

Tests of Fuses.—The most important tests which a fuse must pass successfully in order to demonstrate its reliability are: (1) An insulation or pressure test (*a*) between all live metal parts and earthed metal parts, (*b*) between the two opposite poles of the fitting when no fuse is in place and when a blown fuse is inserted. (2) Tests for operation with gradually increasing current at normal voltage until fusion occurs. (3) Short-circuit tests at normal voltage. In addition to the above tests, measurements should be made of the temperature rise of accessible parts of the fitting and of the voltage drop. A pressure test of at least 1,000 volts above the working pressure should be withstood without breakdown. Experience shows that under certain circumstances a risk of dangerous shock may be created by the use of hygroscopic materials like fibre, asbestos or strawboard between the terminals; leakage may occur sufficient to give a severe shock when it is thought that the operation of the fuse has rendered one terminal "dead." Test 2 is of extreme value as an indication of the behaviour of the fuse under the conditions which in practice most frequently lead up to fusion. The fuse under test should be connected in circuit with an adjustable resistance and a battery or generator giving the maximum normal voltage for which the fuse is designed. The current is increased gradually so that the fuse has time to attain approximately its steady temperature for each value of the current. This procedure is followed in three or four steps until the fuse blows. The circuit should not be opened by other means until all arcing or glowing has ceased. The formation of a continuous arc after fusion must be considered as a property even more dangerous than faulty performance under short-circuit conditions, the latter consisting generally of a violent explosion and scattering of the fuse fitting without necessarily giving rise to the great fire risk which always attends imperfect operation under gradually increasing overload. It is surprising how large a percentage of sample fuses utterly fails under this test.

The value of a short-circuit test as a criterion of the goodness of a fuse depends to a large degree upon the manner in which the term "short-circuit" is interpreted. A fuse of the smallest size may be inserted in an auxiliary circuit on the switchboard of a central station, in the closest proximity to the bus bars transmitting thousands of kilowatts, and the safety of the whole plant may be imperilled by the failure of the fuse to sever a faulty circuit cleanly and promptly. Perfect operation on short-circuit is a matter of careful design, and entails neither increased cost nor elaboration. Since fuses of all capacities are liable to be subjected to short-circuit conditions of the same severity, it is not advisable in specifying the method of carrying out short-circuit tests to differentiate between fuses for various rated currents. Thus the "standard short-circuit" should not be defined as a maximum possible short-circuit current 20 or 30 times the rated current of the fuse under test. An adequate but not too severe short-circuit test for fuses up to 50 amperes rating is provided by the following rules, which have been followed in all tests carried out by the author: (1) The source of current should be a battery having an open-circuit P.D. 10 per cent. higher than the rated maximum voltage of the fuse under test, and capable of giving 500 amperes without the terminal voltage dropping by more than 5 per cent. (2) The total resistance of the test circuit, including the fuse, should be adjusted to correspond to a steady current of 1,500 amperes produced by an E.M.F. equal to the rated maximum voltage of the fuse. (3) On closing the main switch the fuse should blow without a continuous arc being formed or any explosive violence.

The following suggestions are put forward as a basis for the discussion of a specification for standard fuses:—

1. (*a*) *Material for Fuse Wire.*—The fuse wire must not corrode or permanently change its conductivity or physical structure.

(*b*) *Non-interchangeability.*—Fuses up to 50 amperes rated current should be provided with a simple arrangement by means of which the capacity of the fuse which can be inserted by a non-technical user is restricted within definite limits.

(*c*) *Type of Fuse Recommended.*—To facilitate compliance with (*a*) and (*b*) above, and generally to render standardisation practicable and useful, an enclosed cartridge type of fuse is recommended.

(*d*) *Indication of Fusion.*—All fuses must be provided with a simple means for detecting fusion merely by inspection of the fitting.

2. (*e*) *Rating.*—The rated current marked on the fuse shall bear a definite relation to the limiting current, or least current which will produce fusion within four hours. The minimum value of the ratio a = (limiting current)/(rated current) shall be 1·54, and the maximum value shall not be higher than 30 per cent. above the minimum. In a correctly proportioned line of fuses a should decrease from the maximum to the minimum values specified, as the size of the fuse increases from the lowest to the highest capacity. This regulation is based on the assumption that silver is the best metal for fusible links, taking into consideration its permanent character, the small volume required and its "clean" action when breaking the circuit.

(*f*) *Sluggishness of Action and Time Element.*—Standard fuses shall be so rated and constructed that when loaded with 50 per cent. above the limiting current they will fuse within 1 minute. The actual time required for fusion shall be taken as a measure of the "time element" of the fuse.

(*g*) *Standard Rated Currents and Voltages.*—Every fuse shall be clearly marked with its rated current and the maximum voltage for which it is suitable. The standard rated currents and voltages suggested are as follows: *Maximum voltage*, 250.—2, 4, 6 and 10 amperes. *Maximum voltage*, 500.—2, 4, 6, 10, 15, 20, 30, 40 and 50 amperes.

3. (*h*) *Temperature Rise.*—When loaded continuously with 80 per cent. of the limiting current no exposed part of any fuse fitting shall attain a temperature exceeding 100° C. above that of the atmosphere.

(*k*) *Insulation.*—Fuse fittings shall be tested for insulation between terminals with the fusible portion removed and between the live parts and "earth" with the fusible portion in place.

(*l*) *Operation.*—Fuses shall be tested for satisfactory operation on overload and short-circuit in accordance with the specified arrangements for carrying out such tests.

LONG DISTANCE WIRELESS TESTS.*

In its quest for the most efficient wireless telegraph apparatus the U.S.A. Navy Department is now having tests made between its ships and shore stations. While the present installations are giving very satisfactory results, it has been apparent for some time that, no matter how carefully tuned, communication is not certain over any considerable distance without the necessary power behind the spark to overcome the immense amount of interference caused by the wireless apparatus on almost all seagoing vessels of any importance and through atmospheric disturbances.

Some months ago the Navy Department invited tenders for high-powered transmitting and long-distance selective receiving sets, and the National Wireless Telegraph Co., builders of the Fessenden apparatus, secured the contract and are now endeavouring to fulfil the conditions prior to the tender being finally accepted.

Roughly, the scheme is to have a high-power installation at Washington, which will be a kind of master station; the mast to be an iron structural one about 600 ft. in height and the transmitting apparatus to be rated at about 50 kw. Other naval stations will also be equipped, but to a lesser extent, with sets of about 25 kw. capacity, and the battleships and first-class cruisers will have 10 kw. installations, all of high frequency and capable of communicating a distance of 1,000 miles during either daylight or darkness. It is a well-known fact that wireless communication is many times better, possibly as much as three times, during darkness than it is in the daylight; and for a wireless company to undertake to communicate regularly in the daytime a distance of 1,000 miles is an undertaking of no small magnitude. If accomplished it will mean a great advance in the art of wireless telegraphy. The company are partly relying on the theory that with high enough frequency the effect of the sun's rays will be neutralised and communication will be the same either by day or night.

In conjunction with the Navy Department the National Wireless Telegraph Co. began experimenting last August, having installed on the U.S.S. "Connecticut" a high-frequency, 25 kw. transmitter. But, partly from the necessity of having to instal the apparatus, several decks below the main deck and having no adequate means of getting full power into the antenna due to the great loss on account of induction, the tests with the "Connecticut" have for the present been abandoned, and are now being carried on with 10 kw. transmitters, one of which is installed on the scout cruisers "Birmingham" and "Salem" and with the 50 kw. station at Brant Rock, Mass., and the Atlantic naval shore stations. These scout cruisers are admirably adapted for this work, being swift in speed and having wooden masts; the wireless station being placed in the open on the after part of the bridge, thus giving a free lead for the antenna.

A diagram of the connections of the 10 kw. Fessenden transmitter, as installed on the "Birmingham" and "Salem," is shown

in Fig. 1. The motor-generator set consists of a 10 kw. General Electric, 500-cycle, 110-volt, 2,000 revs. per min. single-phase alternator driven by and directly connected to a 14 H.P., 120-volt direct-current motor. Also directly connected on the alternator and motor shaft and on the outside end of the alternator is a synchronous rotating spark-gap consisting of a hard rubber disc, 4 ft. in diameter and 1 in. in thickness, on the periphery of which is a brass band. In this, set at uniform distance from each other, are 30 brass spokes, there being a spoke for each field coil of the alternator. These spokes are 3½ in. in length, and terminate in a small brass ball on the end. The spark-gap is completed by two stationary terminals set at equal distances and opposite each other on either side of the rotating disc, being highly insulated in porcelain and contained in a frame, which also encloses the rotating part, and by means of a worm gear can be turned through a small arc so as to adjust the stationary part in proper relation to the revolving part of the gap. When so adjusted a spoke comes opposite both of the stationary terminals at the exact instant maximum potential obtains in the condenser, thus producing a discharge across the gap for every alternation, or 1,000 discharges per second. The heating prevalent with a high frequency is dissipated by the windage of the rotating member and the spark given off forms a high, pure musical note easily detected through even strong interference. The distance between the stationary and rotating part is from ¼ in. to ⅜ in. on either side, making a total gap of from ½ in. to ¾ in., but which, in fact, amounts to about 1 in. on account of the spark jumping a little before and hanging on after the spoke has passed the terminals.

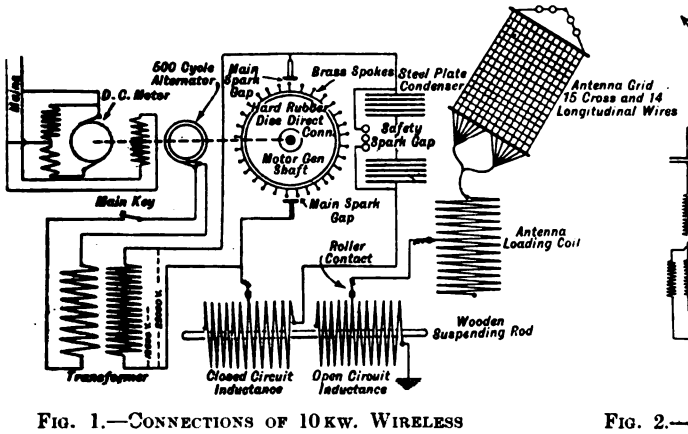

FIG. 1.—CONNECTIONS OF 10 KW. WIRELESS TRANSMITTER.

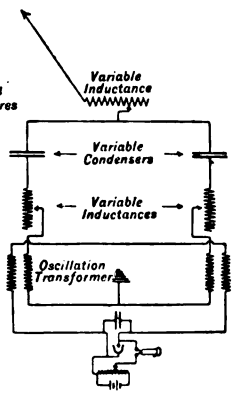

FIG. 2.—SELECTIVE RECEIVER CONNECTIONS.

The transformer is rated at 10 kw. and has oil insulation. The primary voltage is the same as that of the alternator, namely, 110 volts, and from the secondary a voltage of either 25,000 or 12,500 can be obtained. There is a choke coil at each secondary terminal to guard against kicks, and in addition the transformer is protected by an adjustable safety spark-gap connected across its terminals. The current through the primary is usually constant, a spark of one intensity being used, but, when necessary, the current is regulated by varying the field strength of the alternators. The secondary is connected directly across the terminals of the rotary gap, across which, in turn, is also connected the main condenser in series with a variable inductance.

This condenser, for a 10 kw. transmitter, is of small size, having only a total capacity of 0·09 mfd. It is made in two sections, each section being separately contained in a steel cylindrical tank about 1½ ft. diameter and 4 ft. high, suspended from an insulated wooden frame and made absolutely air tight. The condenser plates consist of steel discs, $\frac{1}{16}$ in. thick by 1 ft. diameter. The tanks are subjected to an air pressure of 250 lb., which forms the dielectric for the condenser plates. The series of plates in each tank are connected in multiple, and the two groups connected in series, the series connection being made by earthing a terminal of each condenser to the side of the tank, and the tanks being metallically connected together. The other terminal is taken through heavily insulated porcelain bushings in the top of the tanks. From the two outside terminals and from the common terminal leads are taken to three copper cylinders 1 ft. in diameter, which are adjustable and form a safety valve for the condenser against excessive charging.

The closed circuit inductance connected in series with the condenser consists of 100 turns of $\frac{1}{16}$ in. by ½ in. copper ribbon wound on a wooden cylindrical frame 18 in. in diameter and suspended on a wooden axle. Suspended on the same axle is the antennæ inductance of the same size and turns as the closed circuit inductance and movable in relation toward or from it so that the mutual inductance, and, therefore, the coupling of the two circuits, can be varied, the coupling being in all cases purely inductive. There is still another inductance made similar to the others and placed in series with the antennæ and used as a loading coil by means of which, and the inductive coupling, the wave radiated is made extremely "loose," there being practically but one wave. Each of the inductances can be revolved and by means of a wheel spring contact turns, or parts of a turn, may be obtained. All of the connections in the secondary circuit are made with 1 in. strip copper to keep down induction.

The transmitting key, placed in the primary circuit of the transformer, is of the relay and series break type, consisting of a standard telegraph key shunted by a condenser in series with an electromagnet which operates the main key in the primary. The receiver used with this set is known as the "Fessenden I. P.," or interference preventer type. It tunes extremely sharp, and the only objection to it is the somewhat lengthy time required to make the proper adjustments. The receiver connections are shown in Fig. 2. The antenna is led in singly to a variable inductance coil, after passing through which it divides into two branches and the two branches are brought to a common earth. In each branch or leg is a variable condenser and a variable inductance, the primaries and two oscillation transformers. The detector circuit is inductively coupled and contains the secondaries of the two transformers and the detector, which is of the well-known Fessenden electrolytic type, and having the usual telephones and potentiometer connected in multiple around it. The fine platinum wire is adjusted by a very fine gearing, which is graduated to show the depth of immersion in the electrolyte composed of a 20 per cent. solution of nitric acid. Shunted around the detector is a variable condenser, which acts to neutralise the effect of the inductance, and a sharper coupling is therefore obtained on the transformers.

The antenna as swung on the "Birmingham" and "Salem" is made of standard phosphor-bronze antenna wire and the grid consists of 14 of these wires run lengthwise of the ship and at equal intervals cross-connected by 15 other wires. The lengthwise wires are spaced 3 ft. apart, and the whole is suspended on two 2½ in. iron pipes. The antenna is led down into the transmitting and receiving room in the form of a loop, there being seven wires bunched to form a short fan on either side. This permits the use of either a single or looped antenna for receiving. The suspension of the whole antenna from the masts is by a hemp bridle and down-hauls at both ends and Locke high-tension petticoat porcelain insulators.

Early in March the two scout cruisers left Hampton Roads, Va., with a number of expert National Wireless Telegraph Co.'s operators on board for an extensive test, which, if successful, will mean the general introduction of high-frequency transmitters into the U.S.A. navy.

THE ORIGIN AND PREVENTION OF CURRENTS IN BEARINGS.*

BY L. ADLER.

Summary.—The author discusses the causes which lead to the presence of currents in the bearings of electric machines, and proceeds to show how the injurious effect of the same depends on the current density and bearing surface. Lastly, means are discussed whereby this nuisance can be avoided.

Amongst the various problems and phenomena brought out by the development of electric machines, and more especially of those designed for high speeds, the existence of pulsating currents through the shaft, bearings and bedplate becomes of importance. These currents make themselves chiefly felt by their injurious effects, such as pitting of the shaft and bearing, also by making the oil impure.

In normal generators and motors we can distinguish between those where the main field is produced by continuous current and those where the same is produced by alternating. We shall first consider the flux distribution in the former class. The

Digitized by Google

flux leaving a north pole splits up into two parts, Φ_1 and Φ_2, which pass through south poles on either side, thence to return again to the north pole. From the general equation of the magnetic circuit,

$$\text{Flux} = \frac{\text{magnetomotive force}}{\text{magnetic reluctance}},$$

we have

$$\Phi_1 = \frac{\frac{4\pi}{10}AT}{\Sigma\frac{l_1}{q_1\mu_1}} \text{ and } \Phi_2 = \frac{\frac{4\pi}{10}AT}{\Sigma\frac{l_2}{q_2\mu_2}},$$

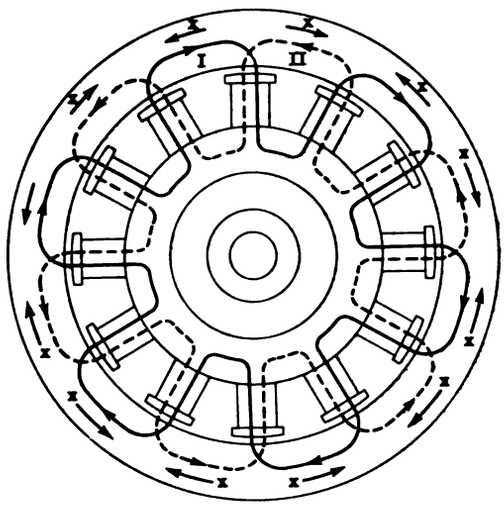
where l_1, q_1 and μ_1 denote the length, section and permeability re pectively of the several parts of the one path, and l_2, q_2 and μ_2 those of the other.

With the usual assumption that the several magnitudes $l_1=l_2$, $q_1=q_2$ and $\mu_1=\mu_2$, it is clear that with a constant M.M.F. $\Phi_1=\Phi_2=\frac{\Phi}{2}$.

In practice, however, it sometimes happens that the reluctances of the two paths are by no means the same, so that the flux is not equally distributed.

Such cases are of two kinds: (1) Those due to the construction; (2) Those due to inequalities in the magnetic circuit.

The first group is by far the more important, and the chief trouble here is due to splitting the stator. From experiments made by Punga and Hess the gap thus introduced in the case of well-constructed parts can be taken as 0·2 mm. to 0·3 mm.



$(x_I)=(x_{II})$.

FIG. 1.

To the latter group belong all such instances as are due to bad erection or faulty material, whereby the reluctance of the path carrying Φ_1 is different from that carrying Φ_2.

To represent the dissymmetry in the flux distribution mathematically we can proceed as follows:—

$$[\Phi_1]=[\Phi_1]$$
$$[\Phi_2]=[\Phi_1]-[X].$$

That is, we assume the armature flux to be equally distributed, and the part which has the greater reluctance to overcome is assumed to have an opposing flux, X, which—as will be seen later—is capable of inducing a pressure in the shaft circuit. Now, in order that a current can exist in the shaft, bearing and bedplate, the flux producing the same must be interlinked with the shaft and pulsate regularly, as in a transformer. To obtain a clearer insight into what goes on, we can imagine the lines of force to pass completely round the machine in two opposite directions, as suggested by Dr. Fleischmann, instead of the usual method of considering each pole pair by itself. The points where the opposing flux X occurs, due to the varying reluctance, comes alternately into the region of north and south pole, so that this flux will consequently fluctuate periodically, and will reach its positive and negative maximum when these critical points lie exactly between two poles. These points of varying reluctance can occur at one or more points in the machine in either one or both of the lines of force passing round the machine. Hence we have the following cases:—

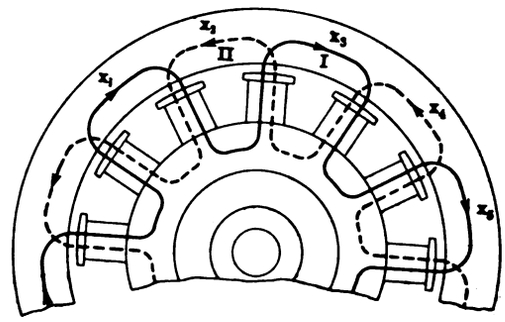
(*a*) The dissymmetry or opposing flux X occurs in both lines of force to the same degree (Fig. 1)—*i.e.*, $X_I=X_{II}$.

(*b*) The dissymmetry occurs in both lines of force, but not to the same extent (Fig. 2)—*i.e.*, $X_I \neq X_{II}$.

(*c*) The dissymmetry only occurs in one of the fluxes (Fig. 3)—*i.e.*, X_I or $X_{II}=0$.

In case (*a*) the two opposing fluxes neutralise one another completely, and no current will be induced in the shaft. In case (*b*) the current through the bearings will be proportional to the difference $X=X_I-X_{II}$. Case (*c*) is really part of case (*b*).

From these possibilities of flux variations in machines with continuous-current excitation a number of conditions for the existence of currents in the bearings can be deduced



$[x]=[(x_1)+(x_3)+(x_5)]-[(x_2)+(x_4)]$
$(x)=(x_I)-(x_{II})$

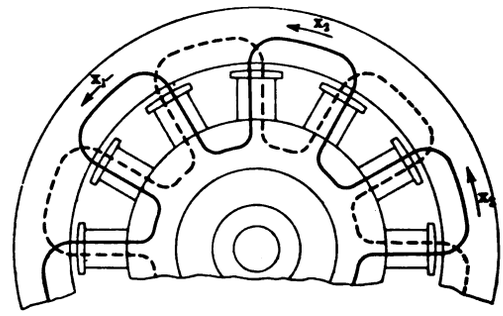
FIG. 2.

For example, if the stator is split into two halves it can be easily seen from Fig. 4 with equal X's we get case (*a*) with 6, 10, 14, 18, &c., pole machines; whilst with 4, 8, 12, 16, &c,. poles, both X's occur in the same line of force round the machine, and we get case (*c*), Fig. 5.

Hence, if the machine is split into n parts, case (*c*) occurs when the number of poles is divisible by $2n$. This gives one fundamental condition for the existence of currents in the bearings due to construction.

Again, when the stator is not round, currents in the bearings can also be set up. According to where the want of rotundity exists, case (*b*) or (*c*) can occur.

On the other hand, if the revolving magnet wheel is not round, or if the poles have not all the same length, or, again, if



$x=x_1+x_4+x_6$
$[x]=[x_1]$
$x_{II}=0.$

FIG. 3.

the distances between the several poles are unequal, none of these can give rise to currents in the bearings; for the resultant flux in the shaft in these cases does not pulsate periodically, but is continuous in one direction.

It is also interesting to see how these currents can be present when plates of different permeability are used. This results in case (*b*). As the rotor revolves the resultant flux changes its sign, and consequently fluctuates with the frequency of the machine.

Coming now to asynchronous machines, it is easily seen that the only practical difference between these and machines excited by continuous current is that in the former they occur, not only when the machine is running, but also when at rest.

Digitized by Google

If now the points where the stator is split lie symmetrical with respect to the two lines of force round the machine, no opposing flux X can exist. Hence, with alternating fields, in addition to the three cases which occur with continuous-current excitation, there is a fourth—namely, where the position of the varying reluctances does not fall directly in either of the two lines of force round the machine, but is symmetrical to both. Thus, in a three-phase motor with split stator, one phase is generally quite symmetrical, whilst the other two are equally unsymmetrical with respect to the place where the stator is split. Under these conditions only the latter two phases can give rise to currents in the bearings. Similarly, with two-phase machines, one will generally give rise to these currents, whilst the other will not.

Though the theoretical possibility of dissymmetry in machines may be great, yet in practice only those cases are of importance where the flux and currents in the shaft assume appreciable magnitudes. Let R be the reluctance of one of the two lines of force round the machine, and r that corresponding to the existence of the flux x in the shaft (in split stators the reluctance where split occurs), then we have

$$\Phi_1 = \frac{\frac{4\pi}{10}\Sigma AT}{R}\ ;\ \Phi_1 - X = \frac{\frac{4\pi}{10}\Sigma AT}{R+r}.$$

Then the value of r/R will be a measure of the magnitude of X. The larger the diameter and the larger the number of poles in the machine the smaller r/R will be. Hence, in high-speed machines with few poles, the phenomenon of currents in the bearings will be more pronounced. The ratio r/R will also be smaller the larger the ratio of ampere-turns required for the

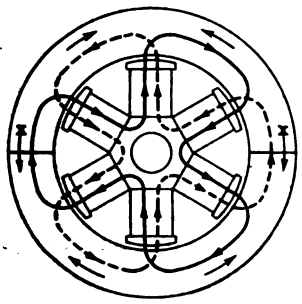


FIG. 4.

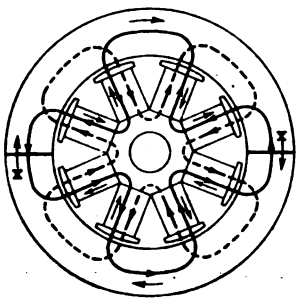

FIG. 5.

gap to total ampere-turns. Thus induction motors will be much more liable to such currents than synchronous machines, which have larger gaps.

Owing to the very varying contact resistance between shaft and bearing and bearing and bedplate (resistances of the order of 0·001 to 0·00001 ohm and less), it becomes impracticable to calculate these currents. The important factor, however, is the current density. But the magnitude of the bearing surface is also indeterminable. It must suffice, therefore, to know what magnitudes the currents and current densities in a machine can assume, and prevent the same by suitable means.

To find out the value of the current density which can cause damage, tests were made for several weeks at the works of the A.E.G. Union Elektrizitäts-Gesellschaft, in Stadslau, with various shafts and bearings through which known currents were passed. As a result of these it was found that, with ordinary soft metallic alloys for the bearing linings, harmful effects on the shaft were produced when the density exceeded 15 to 20 amperes per square decimetre of bearing surface. Since now the current density is under 15 amperes per square decimetre in most practical cases, the shaft surface will be seldom injured by these currents. This is an advantage, for it is much simpler to re-line a bearing than to turn down the shaft.

Along with the pitting of the bearing the oil loses its purity completely on account of the metallic particles set free. An investigation, however, showed that these impurities were of a mechanical nature rather than chemical.

The quite black discoloured oil has a considerably higher viscosity than pure oil, which explains why the presence of currents in the bearings is very seldom due to the warming up of the bearings.

For the purpose of measuring the currents in the bearings of a machine, the bearing was completely insulated from the bedplate by means of a sheet of presspahn, also metallic contact of the bolts was prevented by means of insulation. An ammeter was then placed between the bearing and bedplate. Care had to be taken to make the resistance of this path as low as possible to prevent these currents being diminished.

Measurements were taken on a 12-pole three-phase induction motor built for 700 H.P. at 3,000 volts, the stator of which was split. The pressure between bearing and bedplate was 1·3 volts with normal working pressure applied to stator. At rest, the current in the bearings measured 99 amperes; when running this fell to 75 amperes. This large decrease in the current when running was due to increased resistance caused by the better supply of oil between the contact surfaces than was the case when at rest. With alternating currents the variation of the resistance of the oil layer varies little with the current, whilst with continuous current the resistance falls off rapidly as the current is increased, and reaches a minimum with a current density of about 6·5 amperes per square decimetre. This characteristic property with continuous current may be due to electrolytic action. In another case of a 16-pole three-phase motor for 600 H.P. at 5,000 volts, the current in the bearings decreased from 150 amperes at rest to 50 amperes when running. The pressure between bearing and bedplate was 1·8 volts, so that the loss in energy due to these currents is only a small fraction of the total losses of the machine.

From the foregoing it will be seen that by facilitating the lubrication and improving the bearing surface the currents through the latter can be greatly reduced. As an example of this, it was found that by carefully scraping a bearing which had begun to show signs of pitting, the current was reduced from 200 to 35 amperes.

Another means adopted by certain firms for preventing these currents passing through the bearings is to provide a shunt path by means of placing a special ring on the shaft and leading the current directly to the bearing pedestal by means of copper brushes. Measurements made by the author, however, showed that, owing to the low resistance of the path through the bearings, this method only reduced the current to about two-thirds or one-half of its previous value.

The only means of preventing these currents entirely is to interrupt the circuit. Though several ways for doing this suggest themselves, the simplest and most practical is doubtless the insertion of insulation between bearing and bedplate, and also insulating the bearing bolts, if necessary. This method can also be applied to machines already in operation.

ELECTRICAL TRANSMISSION OF MUSIC.*

DEVELOPMENTS IN THE CAHILL TELHARMONIC SYSTEM.

The general features of the Cahill Telharmonic system † for generating currents of the proper frequency and amplitude at a central station, and superposing and transmitting them to numerous distant points for the purpose of producing music by means of electromagnetically vibrated diaphragms, are well known. During the past three years important changes have been introduced in the equipment, and the results now being obtained with a larger plant, which is being completed in the Cahill laboratory at Holyoke, Mass., are even better—in some ways strikingly better—than those secured with the equipment formerly in service in New York. The power and breadth of effects and the range of expression have been greatly increased. The mechanism has been simplified and the keyboard can now be manipulated by any skilled organist or piano

* Abstract of an article in the "Electrical World."

† A short description of the Cahill telharmonium was given by Sir W. H. Preece in a lecture before the I.E.E. in March, 1908. See THE ELECTRICIAN, March 20, 1908, p. 873.

Digitized by Google

player after only a few trials, with results much more pleasing than they can obtain with the instruments upon which they have spent years in study and practice. But, notwithstanding this, the instrument has a new technique, a thorough mastery of which is not easily obtained.

Before considering the improvements in detail it may be of interest to mention what was desired in building the new plant. The ability of the New York plant to produce a wide range of orchestral timbres and to control the loudness of the note at every instant, by the human touch, was evident to all who saw and heard it; but it fell short of the inventor's ideal. Each switchboard represented a voice, but to produce the full, rich, many-voiced effect of a fine orchestra, quite a number of switchboards are required. Dr. Cahill's design contemplated five switchboards, with a large number of generators, for the New York plant, but the great expense of that pioneer work compelled a large reduction in the number of generators and the omission of three of the five switchboards. The distinctive tone and timbre of the music were there, but the full orchestral effect which the inventor desired was not. Notwithstanding these economies the original New York plant cost almost £40,000.

Another of the difficulties with the original New York plant was that on account of the interactions or reactions of the electrical circuits, the more keys of any one keyboard were depressed at the same instant (that is, the fuller the chord) the less loud each individual note became; and a point was easily reached where the loudness and strength of a chord were less than that of a single note. In the new telharmonium the circuits, switches and transformers have been reorganised in such a manner that full chords can be played on the same manual and switchboard, without any appreciable diminution in the strength of the individual notes, through the reaction of the circuits.

Persons who have heard the telharmonium, or dynamophone, as Dr. Cahill prefers to call it, have usually been surprised at the round and powerful tones which were produced from an ordinary telephone diaphragm. This responds well to powerful electrical vibrations so long as only one note is used. It also responds well for many chord effects, but there are other chord effects, particularly close chords in the bass, which if taken *fortissimo*, produce an unmusical sound—almost a growl. Dr. Cahill found two remedies for this defect. One was to produce one bass note from one diaphragm and line and another bass not from another diaphragm and line. This method obviously required a multiplication of lines and receivers, thereby involving a great increase in expense. Another remedy was to open up the chords in the bass. This method, however, involved the rearranging of the music in many cases. These difficulties have been completely overcome by a new receiver, described below, which was designed by Mr. A. T. Cahill, who is associated with his brother in the electrical work.

The new plant is much larger than the original New York plant. That plant had eight sections or panels of generators. The new plant has 24 sections in operation, with provision on the main frame and in the gearing system for others to be added later. The new sections are smaller and contain a smaller number of generators, but the individual generators, or at least those of high frequency, are much more powerful. In fact, the generators of the very highest frequency have many times the output ratings of the corresponding alternators in the New York plant. Almost the only feature of the New York equipment retained, without change, in the new plant, is the type of alternators, which are inductor machines. Even here, however, there have been changes in the details of the winding and in the shaping of the pole pieces, &c., the result of a long series of experiments.

Each panel of generators is mounted upon a steel shaft about 8·5 in. in diameter, which runs in a cast-iron shell. These shells are assembled upon a steel main frame. The main frame is approximately 65 ft. long, 13 ft. wide, and is built of 20 in. steel beams, mounted upon masonry. Great strength is apparent in the framework and foundations. The result is that the 24 high-speed shafts, before mentioned, each carrying a different group of inductors, run quietly and without any perceptible vibration.

The steel shafts, carrying the inductors, are mounted on ball-bearings of chrome-nickel steel. This feature alone is interesting, since this immense machine, with perhaps the most complicated gearing ever built, has 140 alternators, all running at high speeds on ball bearings. The saving of power in the bearings alone is estimated at more than 150 H.P.

The switchboards, even in their improved form, are of so complicated a nature that a brief description is impossible. The musical conditions are so far different from those of lighting circuits that open-circuit transformers seem to give better results than the closed-circuit transformers.

The new receiver, by which the electrical vibrations are converted into sound waves, is very different from that of the ordinary telephone. It has a much larger and heavier diaphragm—about 10 times as large and three times as thick. A more powerful magnet system is used and the disposition of the field and coils is strikingly different from that in common use. Partly as a result of the increased size and weight of the diaphragm, partly from the greatly increased strength of the magnetic system, partly from the novel disposition of the same and the novel shape of the air passages, a most striking effect is produced. A single diaphragm responds powerfully to any sound, from the deepest bass to the highest treble of the machine; to a pure tone or a highly composite tone; to a single note or to a full chord. The volume and purity of the sound is very striking.

The inventor has expressed the conviction that the most important musical effects of a large and fine orchestra can be produced electrically by the use of, say, 10 manuals, with one performer for each and a sufficient set of generators to furnish all of the necessary harmonics. The music, of course, of this electrical orchestra would not be exactly the same as that of the orchestra of bows, wood-winds, and brass. It would certainly be better in some ways; it might not be so good in others. All the musicians who have seen the new telharmonium are in love with it. And almost every person who hears it considers it as the music of a future that ought to begin at once. The new plant has cost, up to the present, about £40,000.

The inventor claims that for £60,000 a powerful plant, with eight good switchboards, can be built at the present prices of labour and material, while three good switchboards and enough generators to make a respectable beginning in a city having 200,000 or 300,000 inhabitants can be furnished for £25,000. With such reductions in cost, combined with the great improvements in the musical effects before described, the electrical music ought to come into general use at an early date.

The improvements made in the new plant may be briefly stated to consist in a great improvement in musical effects, combined with a great reduction in the cost of the plant. This reduction in cost arises chiefly from the greatly increased power of the high-frequency generators and various improvements in the generators and their gearing, a great simplification in the switchboard work, and the improved receivers by which a single receiver and a single pair of lines is made to do the work which formerly required several receivers and several pairs of lines. The improvements in musical effects arise chiefly from the greater strength of the highest notes and of the higher harmonics, the improvements in the expression devices, and the simplifying of the keyboard and switchboard work, making it much easier for a performer, familiar with the pianoforte or pipe organ, to play upon the new telharmonium.

ELECTRICAL EXHIBITS AT THE BRUSSELS INTERNATIONAL EXHIBITION.

(*Concluded from p. 273.*)

Among the other electrically-driven machines exhibited by Messrs. Butler is a planing machine suitable for work up to 6 ft. in length and 2 ft. 6 in. square. The motor is mounted on a bedplate fixed to girders at the top of the two main uprights carrying the tool. The driving is arranged by a raw hide pinion on the armature shaft, gearing into a spur wheel on the same shaft as that to which the main driving pulleys are fixed. A 15 H.P. shunt-wound motor is employed running at a constant speed of 1,000 revs. per min., and the speed of cutting is 40 ft. per minute, while the return speed is 120 ft. per minute.

There is also shown a slotting machine of 10 in. stroke, fitted with a 10 H.P. motor with variable speed ranging between 600 and 1,350 revs. per min., and also a 48 in. vertical turning and boring machine, in which a 10 H.P. constant-speed shunt-wound motor is mounted on the top of the standards forming the main framing. The different speeds are arranged by a five-speed cone pulley, and, as there are two sets of back gear, 15 different speeds may be obtained, the belt-shifting device allowing the belt to be moved from one speed to another without stopping the machine.

Messrs. B. & S. Massey, of Manchester, have an interesting exhibit of power hammers, several of which are electrically operated, this being a somewhat recent departure for this class of work. The hammer is worked by compressed air, the air being compressed by a double-acting reciprocating pump driven through spur gearing by the motor. The air is admitted at the top and bottom of the hammer cylinder, exactly as the steam in a steam hammer. A 2 cwt. hammer is exhibited, a compound-wound motor of 6 H.P.

Digitized by Google

continuous rating at 1,000 revs. per min. being employed. For the drive a raw hide pinion is used on the armature shaft, gearing into a spur wheel, which consists of a heavy flywheel with the teeth on the periphery. The piston in the pump cylinder is operated through a forged steel crank on the flywheel and a diagonal connecting rod.

Messrs. Massey also exhibit a 5 cwt. pneumatic hammer, for which the air is supplied from a separate motor-driven compressor, being used expansively on the down stroke of the hammer. There is also a 3 cwt. stamp by the same firm, with a patent friction drop arrangement, the machine being operated by a motor fixed on the top of the guides for the falling stamp.

As might be expected, there is a good display of American machine tools, and here again one sees the electric drive very much in evidence. Among the many interesting exhibits is a shaping machine for shaping crank shafts up to 32 in., driven by a 7 H.P. motor at 1,000 revs. per min.; two milling machines, one operated by a 7 H.P. motor at 1,000 revs. per min., and the other by a 10 H.P. motor at 900 revs. per min.; a grindstone driven through gearing by a 7 H.P. motor at 1,800 revs. per min; and a turret lathe operated by a variable-speed motor of 11 H.P., with a range of from 400 to 1,100 revs. per min.

Among the other English exhibits, interesting from an electrical point of view, is that of Messrs. C. A. Parsons & Co., of Newcastle-on-Tyne, who show an example of their new type of direct-current armature for a turbo-generator, this being for a 1,000 kw. machine running at 1,800 revs. per min. and generating current at 550 volts. The object of the new construction is to reduce the large air-gap which is necessitated with surface windings, and to provide a fan action which shall keep down the temperature of the conductors. These latter are of solid copper, and are firmly fixed edgewise into slots in the armature core, the end connections being clamped by studs and plates, no binding wire being wound at all over the bars; the cause of most of the accidents with direct-current turbo-generators—namely, the breaking of the binding wire, with its consequent disastrous effects—is by this means entirely eliminated. Messrs. Parsons also show a large model of their patent compounding device for regulating the voltage of alternators on load.

Messrs. Reavell, of Ipswich, who have of recent years been very successful with their air compressors, have erected several at the Exhibition, one for belt drive, one direct coupled to a petrol engine, and one driven by an electric motor. This last-mentioned compressor is of the quadruplex type, with four air cylinders arranged at right angles, all pistons being driven from the central shaft. The output of this machine is 45 cubic ft. of free air per minute, and the motor employed is of 10 B.H.P. and runs at 440 volts. Messrs. Reavell also exhibit a small steam engine coupled to a 10 B.H.P. dynamo manufactured by Messrs. Maudsley, this being a type they have developed for ship's lighting.

In the British Industrial Hall, Messrs. Waygood exhibit one of their well-known electric double-cage passenger lifts for conveying visitors from the ground floor to the gallery. Each cage is capable of carrying seven persons, and the travel is 13 ft. 8½ in., the speed being 110 ft. per minute, with a lower speed if required. The control is by means of a car switch with a detachable handle, being arranged so that the handle returns to the off position immediately it is released. There are also exhibited a model of an automatic electric push button passenger lift and of a hydraulic lift.

Among the few stands that were completely finished on the opening day was that of Messrs. Marryat & Place, of Hatton Garden, London. This firm is showing a 10 cwt. passenger lift gear with push button controller, and arranged to operate a model four-floor passenger elevator. A car switch and rope operated lift controllor are also exhibited. As to the push button controller, a feature is its simplicity. The number of parts has been reduced to a minimum, and all contacts have been removed from the lift well, so that there are only the push buttons and door contacts at the various floors, the controlling panel and selecting switch being in the motor house.

Messrs. Hans Renold are exhibiting in the British section, in addition to many samples of their various types of chains, three complete drives, viz., a patent bearing silent chain, a bush roller, and a block chain drive. The silent chains are capable of running up to 1,250 ft. per minute, and, with special oiling provisions, even faster. Powers up to 500 H.P. can be transmitted, and larger sizes are at present being developed. The drive exhibited is provided with a shock-absorbing sprocket, for use where the driving power or load is liable to sudden fluctuations. The bush roller chains may be run up to 900 ft. per minute, and that exhibited is of 2 in. pitch, and will transmit 20 H.P. at a speed of 450 ft. per minute. The third drive shows a 2 in. pitch block chain 1 in. wide, capable of running at speeds up to 500 ft. per minute. A coal-cutter chain is amongst the exhibits, it being claimed that this chain is more durable and considerably stronger than any hitherto used for the purpose.

As previously mentioned, the German section is quite self-contained and generates the whole of the electric power required for its own purposes. At present the supply is taken care of by a type of generating set somewhat uncommon in England, but very much in use on the Continent, and particularly in Germany—a semi-portable and entirely self-contained arrangement known as a locomobile. There are two of these in the exhibition, one by the firm of Wolf, of Magdebourg-Buckau, and the other by Heinrich Lanz, of Mannheim. They are both employed for driving dynamos, and the former has a horizontal boiler with removable tubes, a superheater being placed just behind the fire tubes, and the ejector condenser underneath with the pump driven off the main shaft. There are two cylinders, each with a balanced piston valve, and there is a flywheel on each side of the crank. These flywheels also serve as belt pulleys, two dynamos placed on the floor being driven by means of belts. It is stated that the coal consumption is under 1 lb. per effective horse-power-hour, and the steam consumption less than 8 lb. per horse-power-hour, from which it is evident that the absence of piping has a very beneficial effect on the economy of the plant. The power of the machines shown at the exhibition is 650 H.P.

The exhibit of Messrs. Lanz is even larger than that of Wolf, and is said to be the largest in the world. The main details of construction do not differ widely from the machine described above, except that there is but one dynamo. This is driven direct from the main shaft, and is mounted on a platform about the level of the top of the boiler, thus forming an even more compact arrangement. A heavy flywheel is provided on the other side of the crank, and this overhangs the boiler.

Another exhibit of Messrs. Lanz, who have a very imposing display, is a four-cylinder steam engine of 6,000 H.P. for the propulsion of a torpedo boat. On the end of the shaft remote from the propeller is a direct-coupled dynamo for supplying electric power to the ship.

The exhibit of Messrs. Bergmann, of Berlin, forms one of the most remarkable features of the entire exhibition. On their stand in the main machinery hall in the German section a 10,000 H.P. turbo-alternator has been erected. This is the biggest unit in the exhibition. The steam turbine is of the single-cylinder Bergmann type, which has attained considerable success on the Continent, and the manufacture of which has recently been taken up in this country by Messrs. Dick, Kerr & Co. Its speed is 1,500 revs. per min., which is high for this large output, and hence the overall dimensions seem relatively small. There are four nozzles, whose spindles are grouped round the main stop valve spindle, and they are operated by the main stop valve handle, which is not fixed. The alternator, which is totally enclosed except for the usual opening at the top, has an output of 8,000 k.v.a., and the exciter, which is on the same shaft, has no end bearing for its armature. There is, further, a turbo-generator of 2,500 H.P. for supplying current to the German section, and a high-speed rotary converter of 1,000 kw., with a commutator and slip-rings for three-phase current at each end. Numerous small motors for all purposes and a model "remote control" switchboard are also exhibited.

In the locomotive shed, where several of the most modern of German steam locomotives are installed, Messrs. Bergmann show a motor car for suburban service, running on a normal gauge track, which, though not entirely novel, will be of much interest to many English engineers. There is a totally-enclosed direct-current motor geared to each axle suspended from the frame of the car, and the current is derived from a 50 H.P. dynamo driven by a benzine motor direct coupled and mounted on the front of the car. The engine and dynamo are enclosed in a chamber with doors at each end, so that both the engine and commutator are readily accessible. The cylinder is water cooled, the radiator being fixed just above and cooled by a fan, which is driven by bevel gearing off the end of the armature shaft. The motors are of 30 H.P., at one hour rating, and the maximum speed of the car is about 50 miles per hour, the number of passengers carried being about 40.

Among Messrs. Bergmann's other exhibits is a 30,000 kg. overhead electric travelling crane spanning one of the bays; while there is, further, an unusual type of traveller, in which the crane house is made to traverse and a revolving jib is fitted.

A new type of rotary engine evolved by the Internationale Maschinenbau-Gesellschaft, of Hanover, is also exhibited, coupled to a 170 kw. direct-current generator, and some secrecy is being maintained concerning it. There are two cylinders, exactly like the high and low-pressure cylinders of a compound steam turbine, and the steam, in fact, expands partially in one and is then delivered into the other, where it expands to exhaust pressure, a bearing being provided between the two cylinders. The remarkable point about the machine is its low speed—only 150 revs. per min.—and a very low steam consumption is claimed. Naturally, owing to the low speed, the machine is very much larger than a steam turbine set, resembling, in fact, a 500 kw. generator in outward appearance.

The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube. 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-ninth issue of the Supplement was published (Gratis) with the last number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPEOIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

In reviewing the work of the Institution during the past session we think it may be said that the Papers presented, and the discussions to which they have given rise, have been up to the usual standard. Many Papers have been read more than once, and the advantages of an organisation which permits a Paper to be read at more than one centre have certainly been apparent. The number of original communications also has increased by, roughly, one-third, which must be considered a good sign that the Institution is attracting work of a kind which, although not suitable for discussion, is nevertheless worthy of publication.

In other directions also the Institution has been active, and in many respects these activities must be considered as important as the reading of technical Papers. In the Report we find that provision is being made for issuing another revised edition of the Wiring Rules, and to this end tests are being made at the National Physical Laboratory with reference to certain data in the rules. The Model General Conditions for Contracts are also being revised. It will be remembered that these were due in the first instance to the energy of Mr. ROBERT HAMMOND, and after careful discussion they were duly issued some years ago. Since then, however, they have remained unaltered, and now the Council appear to think that the time has arrived when

Digitized by Google

modifications should be considered. To this end the Council have had the benefit of co-operation with the Cable Makers' Association, the Electrical Contractors' Association, the Incorporated Association of Electric Power Companies, the Incorporated Municipal Electrical Association, the National Electric Manufacturers' Association and the Tramways and Light Railways Association. It is well that all the interests concerned should have a voice in a matter of this kind, and we are glad to see that this policy of co-operation is being adopted.

Another point of interest in the annual report is that the Council have adopted the Rules for Professional Conduct recently adopted by the Institution of Civil Engineers, and we gather that the Council will seek powers to enforce these rules. This is always a point of difficulty in such matters, as rules are of very little value unless they can be duly enforced. With regard to the rules themselves, they are good so far as they go, but there are inherent difficulties in the provision of suitable rules by any Institution whose membership includes engineers of very different classes. Although it is not definitely so stated, the term "professional conduct" really refers to the practice of the consulting engineer. As the Institution of Electrical Engineers does not consist exclusively of consulting engineers, it is difficult for the Council to adopt rules which really meet the case, as other conflicting interests are to be found. The result of this is to be seen very clearly in the third rule, which practically states that an engineer, while acting in a professional capacity, shall not at the same time act as agent for any contracting or manufacturing company with which he may have occasion to deal on behalf of his clients, or have any financial interests in such business without disclosing the fact in writing to his clients. This one clause renders the rules practically inoperative on the very large question of contractors who act as consulting engineers, a question which is a most legitimate grievance on the part of engineers who are really consultants, and it renders the fact very clear that these questions can only be dealt with by an independent organisation.

Among other spheres of activity we may mention that certain points in legislation have been considered by the Council during the past year, and a committee has been appointed to report upon the question of electrical driving of textile mills. At present data are being collected, with the collaboration of the local sections interested, and in view of the report recently issued under somewhat curious circumstances by the Bradford Engineering Society we are sure that this step by the Council will be very much welcomed. It is extremely important that this question should be cleared up authoritatively.

The election of the Council for the new session has this year been marked by the unusual occurrence of a nomination beyond those due to the Council. This principle, as a principle, is desirable, but as we deal with this subject elsewhere we need say no more on this particular point.

The time is now approaching when the Institution will be moving into its new building, and will at length be provided with a home of its own. We trust that finance in connection with this new move will work smoothly, and that the Institution will be so far supported by an influx of new members as to relieve the Council of all anxiety. It is a little early yet to judge of the position accurately. At a special general meeting last week the members were asked to sanction the expenditure of another £10,000. The arguments on which this request was based were not entirely convincing, as the amount actually required was only a small proportion of this sum, and the possibility of spending the greater proportion apparently will not arise for another two or three years. We do not doubt, however, that the Finance Committee will keep a firm hold upon the expenditure. This is certainly desirable, though, on the other hand, we think it is far better that a clean sweep should be made at the start, and that the building should be put into such a state that it will meet the needs of the Institution for a good many years to come.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Electric Waves. By W. S. FRANKLIN. (London: Macmillan & Co.) Pp. ix. + 315. 12s. net.

This treatise is planned to exhibit in as simple a manner as possible the principal mathematical methods at present available for handling high and low frequency alternating-current problems when the E.M.F.s and currents are not simply harmonic, and when the capacity is not concentrated. The treatise is intended for practical people and not for mathematicians; but, of course, the book will not be easy reading throughout except to those with a considerable mathematical equipment. In spite of this fact, large portions of the volume can be understood without the assistance of the differential calculus, or even trigonometry—the author makes such excellent use of mechanical analogies. Indeed it is not too much to say that the first two chapters of this book comprise the most lucid short exposition of general wave theory that the present writer has yet happened upon.

The first part of the book deals in turn with water waves, wave trains and stationary waves, electromagnetic waves, waves along and oscillations on cables, the general electromagnetic wave equations, and electric wave telegraphy. The author discusses the surgings on transmission lines and the reflection from inductive and non-inductive terminal apparatus, with exceeding simplicity. The explanation of the reduction of line losses in telegraphy and telephony by loading the line with inductance, and the reduction of distortion by leakage is similarly carried through with what may be styled a clarified Heavisidean spirit. Throughout even the mathematical part the author keeps his eye on the practical side. The development is here again based largely on the methods of Heaviside; but in the explanation of curl, divergence, vector potential and so forth, the mind of the ordinary reader is supported by ample provision of that Cartesian scaffolding which Heaviside spurns scornfully away. The chapter on electric wave telegraphy is the weak one of the book; it takes the whole of that subject in ten pages, and really might as well have been left out.

Part II. of the work is devoted to harmonic analysis. Practical analysis is represented by a very full description of the Fischer-Hinnen method of evaluating the Fourier coefficients in given non-harmonic curves. This analysis is applied to an examination of the causes of non-harmonic E.M.F.s in alternating-current generators; and allied matters such as the influence of higher harmonics upon core losses in transformers, and the influence of triple harmonics on the current and voltage, and on the power factor in three-phase systems, are touched upon. Appendixes deal with the

Digitized by Google

practical calculation of the inductance and capacity of transmission lines, and certain smaller matters.

The work is too interesting to be left to students; it could be read with pleasure and profit by all scientific electrical engineers.

W. H. ECCLES.

The Prevention of Industrial Accidents. No. I.—GENERAL. By F. E. LAW and W. NEWELL. (New York, The Fidelity & Casualty Co.) Pp. 194. 25 cents.

"An ounce of prevention is worth a pound of cure" is a befitting text for the title-page of this handbook, to which we are pleased to extend a hearty welcome. Whilst the valuation at which human life is held differs considerably in various countries, no one will question the desirability of preventing accidents. It is interesting, but perhaps not surprising in view of German "thoroughness," to notice that the authors have turned to Germany for exact information in regard to the causes of accidents in industrial concerns. The published statistics in that country show that no less than 58 per cent. of the total number of accidents recorded are due to the negligence of employers or employés, the remainder—namely, 42 per cent.—being due to the inevitable risks of employment. As the United States have not progressed to anything like the same extent as many other countries in minimising industrial accidents, the authors remark that probably far more than 58 per cent. of the accidents that occur in the States are preventible. That an extensive field exists for preventive measures may be gathered from the following remark in the "Bulletin" of the Bureau of Labour (September, 1908): "Upon a conservative estimate, the total mortality from accidents in the United States among adult wage-earners is between 30,000 and 35,000, of which it should not be impossible to save at least one-third and perhaps one-half by intelligent and rational methods of factory inspection, legislation and control. In addition, there were approximately not much less than two million non-fatal accidents."

A large insurance company should be particularly qualified to speak with authority on means for the prevention of such accidents, and the present handbook is undoubtedly a valuable addition to the literature on this subject. The book deals with general precautions, and applies to all industries; but other pamphlets have been prepared dealing with the conditions peculiar to certain industries.

Particular emphasis is laid on the large part played by ignorance and carelessness as causes of accidents, and to the duty of employers to make strict rules for observance by employés. There are also many safety devices which can be installed at small cost. Safety devices are considered under the following heads: Steam boilers, engines, electrical apparatus, elevators, the factory and wood-working machinery. In no case is the name given of the makers of the various safety devices described, but it is stated that they will be supplied on application being made.

In the section dealing with electrical apparatus undue emphasis is, perhaps, laid on the use of rubber gloves. Thus, the recommendation that in oiling, cleaning, or adjusting any part of a dynamo, motor or transformer in service the attendant should wear rubber gloves is scarcely practicable, or perhaps we might say necessary, at any rate in the case of low-voltage machines. This also applies to the suggestion that the handles of oil cans and wipers and cleaners should be insulated. As to portable hand lamps, the authors state that the two most important points to be observed are: (1) That there shall be no metallic connection between the lamp-holder and any other metal part of the fitting; and (2) that the flexible wires in passing from the lamp-holder shall not be led through a metal tube or otherwise touch any metal part of the fitting. It will be remembered that particular emphasis was laid in the recent official notes on the Home Office Regulations on point (1) above, the majority of hand lamps hitherto used failing to comply with this condition.

Automatic elevators are by no means unknown in this country. The authors consider such installations inadvisable, and in their opinion each elevator used for passenger service should be in charge of an operator.

THE DETERMINATION OF THE EFFICIENCY OF DIRECT-CURRENT MACHINES BY THE HOPKINSON TEST.

BY C. V. DRYSDALE, D.SC.

There is probably no method of testing the efficiencies of direct-current machines which is so much used in commercial work as the Hopkinson test or Kapp's modification of it; and no method about which so little seems to be known. The method is described in practically every text book, but the writer has not met with one in which the details of the test and the analysis of the results have not been shirked. All that is usually stated is that the combined efficiency is the ratio of the generator to the motor current and that the efficiency of each machine is the square root of this combined efficiency. When we have a pair of machines of high efficiency running at approximately full load this may not be far from the truth, but with small machines, and with any machines at low loads, the conditions of load for the two machines are so different that it is absurd to assume their efficiences as equal, and it is absolutely impossible to obtain a rational efficiency curve in this manner.

In THE ELECTRICIAN of April 15th Mr. W. C. Clinton has done valuable service by calling attention to the unnatural and unequal conditions under which the two machines are run in the ordinary Kapp method, and has shown us how these inequalities may to a considerable extent be rectified by an auxiliary battery. He has also properly apportioned the copper losses between the machines, which is the only rational method.

As the matter is of some importance the following description

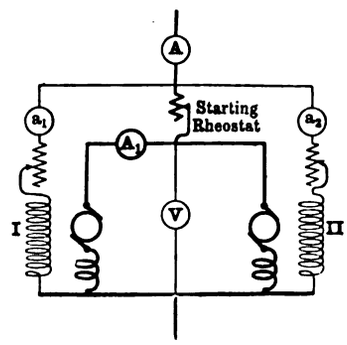

FIG. 1.—CONNECTIONS EMPLOYED.

of a simple method of carrying out the test, which seems fairly satisfactory although not pretending to be theoretically correct, may be of interest. Fig. 1 shows the method of connecting up and needs no explanation. The regulation of the currents is effected by the rheostats in the shunt fields in the ordinary manner.

If the excitation of machine I. is weakened so that it becomes the motor, we have obviously:—

$$\text{Motor input} = (A_1 + a_1)\ V.$$
$$\text{Generator output} = A_1 - A + a_1)V.$$

On the other hand, if II. is made the motor, by weakening its excitation, we have:—

$$\text{Motor input} = (A_1 + A - a_1)V,$$
$$\text{Generator output} = (A_1 - a_1)V.$$

The difference between the input and output in either case is AV, the total losses in the two machines. So far we are rigidly correct.

If the machines are of fairly high efficiency it does not require a great change of speed or excitation to produce the circulating current between the machines, and we may assume the iron and frictional losses as nearly constant and equal for each machine. If then we subtract the value A_0V, the watts when the machines are both running under equal conditions or at "no load," from the value of AV when running under any given load, the excess is approximately the sum of the C^2r losses in the armatures of the two machines. The current in the armature of machine I. is A_1, and in that of machine II.

is $A_2 = A_1 - A + a_1 - a_2$. Hence we may divide the above copper loss $(A - A_0)V$ in the ratios of the squares of the armature currents, and the copper loss in I. is $\frac{A_1^2}{A_1^2 + A_2^2}(A - A_0)V$, and in II. it is $\frac{A_2^2}{A_1^2 + A_2^2}(A - A_0)V$, which are obtained without measuring the armature resistances. The loss in each machine is then taken as half the iron and friction loss, or $\frac{A_0 V}{2}$, together with its own share of the copper loss as above obtained. We thus obtain the motor output = generator input, and thence we can calculate the efficiency of each machine separately, and plot its curve of efficiency against output.

The following table and the efficiency curves, Fig. 2, were

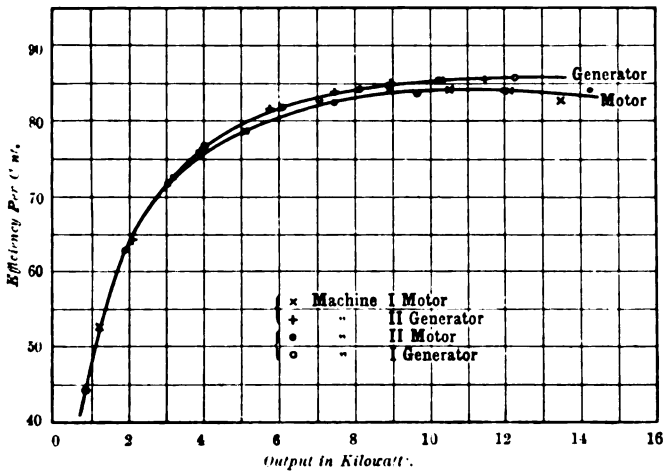

Fig. 2.—Efficiency Curves from Hopkinson Test.

obtained in the above manner by the staff and students in the evening practical demonstrations at the Northampton Institute. The tests were made on a pair of 15 kw. machines by the International Electric Co. of Liège, each being intended for 100-110 volts at 1,150 revs. per min. The mode of constructing the table will be obvious from what is said above.

It will be noticed that the two tests with machine I. and II. as motor, respectively, give four sets of points for the motor and generator efficiencies. Up to about 4 kw. all these points lie on the same curve, but above this the motor curves separate from those of the generator, until the difference is a little over 1 per cent. at about 12 kw. This difference is probably due to the fact that the motor having had its field weakened should not have had half of the "fixed" losses apportioned to it, but the mean of the two curves should be approximately correct. Previous tests on the machines had shown them to be most accurately similar in all respects.

Fig. 3 shows the result of a brake test on machine I. as a motor, taken on the writer's regenerative brake. Unfortunately it was only found possible to carry the test as far as 11 kw., but the observations agree remarkably well with the upper of the two curves in Fig. 2. In the brake test, however, the P.D. was always kept at 110 volts, while in the Hopkinson test it fell from 105 to 102 or 103 volts as the load was increased. Had the voltage been maintained, the mean curve for the Hopkinson test obtained in this way would have very closely coincided with the direct test, and this would appear to indicate that this mode of carrying out the test would be sufficiently satisfactory with machines from 10 kw. upwards in practice. This only applies, of course, to machines having a fairly horizontal speed or voltage characteristic, and not to series machines. It should be noted that considerable care was taken to have the brushes of each machine set on the neutral axis before the test commenced. It might, perhaps, be possible to obtain the required regulation of the load, without change of the field and iron losses, by regulating the brushes, but the writer has had no opportunity of trying this.

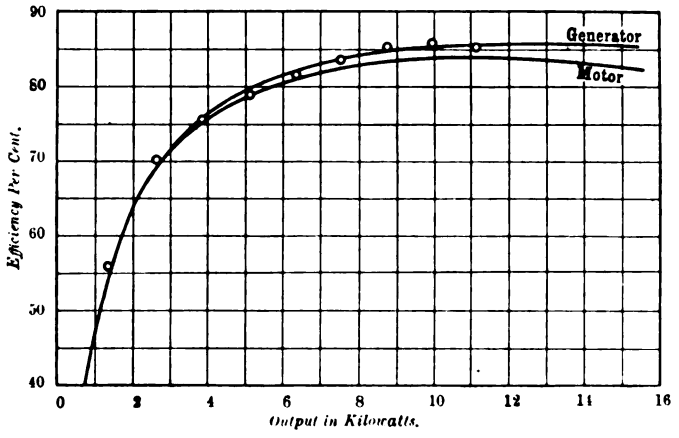

Fig. 3.—Brake Test.

The speed of the machines during the Hopkinson test varied from about 1,100 at no load to 1,200 at full load, or by nearly 10 per cent. Of course by using an auxiliary battery as Mr. Clinton suggests this could have been avoided.

In conclusion, the writer's thanks are tendered to Messrs. A. C. Jolley, H. Gerrard and A. F. Burgess, and to several students of the Northampton Institute for conducting the above tests.

RELATION BETWEEN TEMPERATURE OF ELECTRODES AND VOLTAGE OF THE ELECTRIC ARC.*

BY C. D. CHILD.

Summary.—A *résumé* is first given of previous experiments to find the effect on the electric arc produced by cooling the electrodes. Some of the experiments were repeated by the author, who found that cooling the cathode of a carbon arc raised the pressure several volts, a smaller increase occurring when the anode was cooled. The anode and cathode pressure drops were measured and both found to increase when the cathode was cooled, the principal increase being in the cathode drop. The increase in potential in different parts of the arc was approximately proportional to the potential existing before the cathode was cooled.

The theory of the electric arc, as at present held, leads us to expect that with cooled electrodes a higher P.D. will be needed to maintain the arc than with electrodes not cooled, but the experimental evidence to a large extent favours the opposite view. It, therefore, seemed worth the trouble to review what has been done on the subject and to repeat some of the experiments.

Many of the earlier experiments are of little value. Such for example as that of De la Rive (1841), who attempted to heat the arc by placing an alcohol lamp under it. Tommasi (1881) formed an arc between copper tubes, and found that when they were cooled by water passing through them the arc was very unsteady and the luminosity became less. This is one of the most satisfactory methods of examining the question, but his results are not as definite as is desired. Cross and Shepard (1885) endeavoured to heat the electrodes by protecting them from convection currents. This method is more satisfactory than some, and yet it is conceivable that the protection would alter the character of the gas sufficiently to change the P.D. Lecher (1887) used three methods for changing the temperature of the electrodes. The first was to warm the electrode with a gas lamp; the second was to wrap fine copper wire about the electrodes; and the third method was to cool the electrode by immersing it in a mercury bath, which was in turn kept cool by running water. This would apparently be a suitable method, providing that the mercury vapour did not pass into the arc.

The experiment of Hertzfeld where he blew cold CO^2 into the arc was valueless, for the reason that the change in the character of the gases and the distortion of the arc by blowing into it would produce far greater effects than those produced by cooling the electrodes. Schultze used the same method as that of Tommasi, experimenting with the arc between copper electrodes which could be cooled by passing water through them. He found that cooling the cathode raised the P.D. about 1 volt, cooling the anode raised it about 4 volts, and cooling both electrodes about 6 volts. Where an oxide is formed by the action of the arc this effect was not found. Even with iron the effect could not be shown. This was partly due to the smaller heat conductivity of the iron.

Mitkiewitz found that a current of 2 amperes could be passed through an arc with a P.D. of only 2 volts if the anode was heated in an oxy-hydrogen flame. But it is a question whether this is an arc at all and not merely the discharge produced by a hot flame. Stark and Cassuto cooled the electrodes by placing a small quantity of the substance to be examined on the top of a water-cooled jacket. They were unable to determine with certainty any change when carbon electrodes were used. With copper electrodes they found the voltage much lower when the arc was several millimetres long and no change when it was 2 mm. long. From this they concluded that with still shorter lengths the voltage would be higher with hot electrodes and that the sum of the anode and cathode drops is greater with hot electrodes than with cold ones. Malcolm and Simon using copper electrodes and small currents with arcs 4 mm. long found that the cooled electrodes required higher voltages. With currents varying from 0·4 to 1 ampere the voltage was from 20 to 5 volts higher when the anode was cool than when the electrodes were hot, and 40 to 10 volts higher when the cathode was cooled.

Of the experiments, therefore, which are least open to objection there are two sets, and these two arrive at directly opposite conclusions. Cross and Shepard using carbon electrodes came to the conclusion that cooling the electrodes lowered the required voltage, while Schultze, Clarke and Cassuto, and Simon and Malcolm, using copper electrodes, reached the conclusion that cooling the electrodes raises the required voltage. It, therefore, seemed worth while to repeat some of these experiments and to find the cause of the discrepancy.

Electrodes Cooled by Water-jacket.—The experiment of Cross and Shepard was first repeated. One of the electrodes was surrounded by a copper jacket through which water could be passed. This was made to fit tightly around the carbon, so that no steam could get into the arc. The top of the carbon extended between 1 mm. and 2 mm. above the top of the jacket, which was made out of sheet copper, so that the water would come as near as possible to the top of anode. The carbon was 12 mm. in diameter. The arc was started without any water in the jacket and allowed to run as long as possible without overheating the apparatus. It was then cooled by passing water through the jacket. The P.D. at the terminals of the arc was taken before the anode was cooled and again immediately afterwards. The water was then allowed to flow out of the jacket and the P.D. again noted.

When the cathode was thus cooled there was an increase in the P.D. of 2 or 3 volts. When the temperature increased on drawing off the water there was a decrease in voltage of about 1 volt. It was to be expected that the decrease would not be as large as the increase, since the P.D. would gradually increase, due to the burning away of the electrodes. This change was found to be practically the same for currents varying from 8 to 20 amperes and for lengths varying from 1 mm. to 5 mm., as long as the arc was quiet. With the hissing arc it was difficult to detect any change when the jacket was filled with water. When the anode was cooled, no definite change could be detected, but this may be due to the difficulty of performing the experiment properly. Practically the same effects were observed with solid and with cored carbons, but with a mineralised carbon, such as is used in the "flaming arc," no effect could be definitely determined.

These results are opposite to those found by Cross and Shepard, and to find the cause of the difference the experiment was again performed, but with the water vapour passing freely into the arc. It was found that this caused the arc to go into the hissing form, with, of course, a large decrease in the voltage. It is possible that the decrease in voltage which Cross and Shepard found was due to the change to the hissing form of the arc and not to the change in the temperature of the electrodes. This same experiment was then repeated, using mercury instead of water to cool the electrode, as was done by Lecher, and the vapour of the mercury could pass into the arc freely. It was found that there was a decrease in the P.D. of 10 or 15 volts, when the mercury reached the hot part of the anode. That this was due to the passing into the arc of mercury fumes was shown by the fact that the mercury lines began to appear in the spectrum of the arc even before the decrease in the P.D., and became very prominent at the time of this decrease.

Hollow Carbons Cooled by Flow of Water.—As far as I have been able to learn, the method employed by Tommasi and by Schultze with copper electrodes has not been used with carbon electrodes. It, therefore, seemed worth while to try their method with such electrodes. The arc was formed between a cored or solid 10 mm. carbon and a hollow carbon, outside diameter 12·5 mm., inside 4 mm., connected to a water faucet so that it could be cooled by running water through it.

In the first experiments the hollow carbon was used as cathode. It was found that the voltage always rose when the cathode was cooled. The change in voltage occurred, as nearly as one could tell, at the same time as the change in the luminosity of the cathode. The average of 10 readings gave a rise of 4·5 volts. The average of 10 readings for the decrease when the flow of water had stopped was 1·8 volts. The change in the voltage appeared to be the same for currents varying from 6 to 15 amperes, but increased somewhat as the length of the arc was increased from 2 mm. to 10 mm.

The change in P.D. is not so great when the cooled carbon is used for the anode. It is also more difficult in that case to take satisfactory readings. The arc does not become steady until a crater is formed on the anode and by the time this is done a hole is apt to be burnt through the carbon, so that water flows directly into the arc. As near as could be determined the P.D. increased about 2 volts on cooling the anode, decreasing nearly the same amount on allowing it again to become heated. With thicker carbons the effect was, of course, smaller.

Objection may perhaps be raised against this method due to the fact that the carbon was porous. It is conceivable that steam passes through the carbon and changes the arc by the introduction of a different gas. To test this, steam instead of water was passed through the hollow carbon. This was under a pressure of 5 cm. of water, and might have been expected to have a greater effect than the water, if the effect was due to the passing of the steam through the carbon. But it was found that the passing of the steam had no appreciable effect on the arc. The second test was made by inserting a hollow copper tube within the carbon rod. This would keep any water vapour from coming into contact with the carbon, but it also protected the carbon from the cooling effect of the water. However, there was an increase in voltage each time that the carbon was cooled. This was approximately 2 volts.

Effect of Heating Electrodes.—A second method of studying this

* Abstract of an article in "The Physical Review."

Digitized by Google

problem is to heat the electrode by passing an electric current through it. It was found, however, that when the current was sent through the carbon, the magnetic field about it deflected the arc, so that any effect was masked.

Change in the Cathode and Anode Pressure Drops.—In the explanation of the arc commonly given to-day it is claimed that the fundamental difference between the arc and other forms of discharge through gases is that in the arc the hot cathode allows the electricity to pass from it with great ease. To do this the cathode must have a high temperature, and to produce the high temperature there must be an expenditure of electrical energy in its neighbourhood. The rate at which this is done equals the product of cathode drop and current. It is natural to expect that if the cathode is cooled artificially, it will require a greater expenditure of energy to maintain the needed temperature, and to do this with a given current the cathode drop must be greater. Similarly with any method of heating we should expect the cathode drop to be less.

To test this view, the cathode drop was examined by inserting a carbon pencil 1·7 mm. in diameter between the electrodes of the arc and connecting this through a voltmeter to the cathode. The arc was approximately 4 mm. long and the exploring electrode was placed as near the middle of the arc as possible. The P.D. measured in this way included both the cathode drop and half of the fall of potential through the vapour of the arc, but the method answers for getting an approximation to the cathode drop. Contrary to what had been expected, it was found that there was but a small change in the value of the cathode drop when the cathode was cooled. The anode drop was then examined and it was found that there was here a large change. In one case the total P.D. changed from 41 to 47 volts, the cathode drop from 6 to 7 volts and the anode drop from 35 to 40 volts. It is evident from this that the change in potential produced by cooling the cathode does not all occur near the cathode; and that the change in different parts of the arc is roughly proportional to the potential existing before the cathode was cooled.

In order to test this view, a shunt was placed about the arc and a point on this which had the same potential as that of the exploring pencil was connected to it through a voltmeter. While this connection was made, the cathode was again cooled. At times when this was done the voltmeter would give no reading. At other times there was a small reading in a direction indicating that the ratio of the increase to the original value was slightly greater in the cathode drop than in the remaining part of the arc, but it could be said that the change in the different parts of the arc is nearly proportional to the original potential. While this was contrary to what I had expected, it is not difficult to explain the phenomena observed. It was thought that extra energy would be developed near the cathode, so that the temperature in its immediate neighbourhood would be the same as before. It would appear that what really happens is that the bright spot on the cathode is not as hot as before and that fewer ions pass into the vapour of the arc, and consequently its conductivity is less. This view is also in agreement with the fact mentioned above that the change in potential was found to be greater when the arc was long than when it was short. It apparently follows from this that the anode drop itself depends on the ions produced at some distance from it. There are other facts which would indicate the same. For example, the anode drop becomes very much smaller when a salt is placed in the cathode, or when the cathode is a metal instead of a carbon.

Effect of Heating Anode in Mercury Arc.—Stark, Retchinsky, and Schaposnikoff found that with a carbon anode in a mercury arc the anode drop was much smaller when the anode was cold than when hot. It varied in their experiment from 12·4 volts when the carbon was bright red to 4·7 volts when it was non-luminous. In the experiment described above there was but a very small change produced by cooling the anode. Because of the difference in these results, I repeated their experiment with the conditions as nearly as possible the same as those described by them. While a small increase in the anode drop was at times found to accompany a rise in temperature of the anode, it was one of only 2 or 3 volts, and it was not possible to show definitely that it was due to the increase in temperature and not to an increase in the pressure of the gas.

This, however, would not explain the results of Stark, Retchinsky and Schaposnikoff, for in their experiments the tube containing the arc was not connected to the pump after the arc was started. There was a rise in the pressure of the mercury vapour and the increased amount of vapour *cooled off* the anode so that it became non-luminous. So that with the increase in the amount of pressure there was a decrease in the temperature of the electrode and a decrease in the anode drop. As far as the relations between the pressure and the anode drop, and between the pressure and the temperature of the anode are concerned, these were exactly opposite to that found by myself.

CORRESPONDENCE.

SHORT CIRCUIT LOSSES IN ALTERNATING-CURRENT COMMUTATOR MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The above Paper is of special interest to me in that it was commenced just as my own research on commutation phenomena was approaching completion. During that research I had discovered that parts of the brush surface expanded and lifted from the commutator, and to remedy these evils and further improve commutation I had invented the cooling device and brush holder described in my Institution Paper, the one in that portion published in your issue of May 20th, p. 237, column 1, and the other in that portion published in your issue of May 13th, pp. 183 and 184.

I communicated my results to Dr. Fraenckel and Mr. Lane, and suggested the use in their research of these inventions, as I believed that they would enable them to obtain results of a more uniform character than those which they explained they had up to that time obtained. I am interested to see from their Paper that they obtained more uniform results, and I am surprised that they have failed to refer to my brush-holder and to acknowledge me as the discoverer of the expansion of the brush surface and inventor of the cooling device, the more so as such mention and acknowledgement when they came to publish was agreed upon.—I am, &c.,

Birkenhead, May 28. G. W. WORRALL.

STANDARDISATION OF FUSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the interesting editorial on this subject in your current issue, it is evident that you have misunderstood my views on the "indication" of blown fuses. An efficient and reliable indicator is one of the most important features essential to a practical line of fuses, and in order to show what is, in my opinion, a satisfactory device, an illustration was given on page 17 of my Paper of the "self-testing" indicator which forms one of the best features of the excellent "Zed" fuses which have recently been put on the market. In designing an indicating fuse it is very necessary to avoid impairing the reliability and efficiency of the fuse, *e.g.*, an enclosed type fuse which might be safe for use in explosive atmospheres is rendered unsafe for such use if provided with an external indicating wire of the type in which fusion of the indicator wire burns or scorches a paper label. As is well known to all users of enclosed fuses having an indicator of the type just referred to, this form of indicator is very untrustworthy and often fails to perform its office; for this reason it is desirable that a fuse indicator should be self-testing, *i.e.*, should give visible indication when it is "out of order" as a fusion indicator.

I sincerely trust that after the subject of fuse standardisation has appeared and passed into space periodically for many years, the latest references to the subject may be productive of action and satisfactory results.—I am, &c.,

London, May 28. H. W. KEFFORD.

COMMUTATION PHENOMENA IN DIRECT-CURRENT MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method of commutation investigation described by Dr. Coales and Mr. Wall in your last issue has the great advantage of simplicity, which is not possessed by the methods ordinarily used. This method, however, as the authors state, gives two kinds of oscillations foreign to the desired result, *i.e.*, tooth oscillations and those due to the fact that the number of commutator segments is not infinite. The first kind, athough independent of the load, would probably vary with the position of the brushes, while the second kind would be greatly influenced by both these factors. The second type of oscillation, however, is entirely absent in the method of investigation described in my Paper, and hence the only item

Digitized by Google

foreign to the desired result is a constant one, and as I have shown, is readily distinguished.

This, however, is not the only difference between the two methods, for the presence of a finite number of segments would introduce variations in the observed commutation oscillations, and these could not be eliminated even if it were possible to eliminate the two foreign elements above noted.

The method suggested further involves the use of a battery, which is certainly no less burden than the wrapping of a few turns of wire on the main poles. I hope that Dr. Coales and Mr. Wall will obtain and publish some oscillograms, as I shall be very interested to see them.—I am, &c.,

Birkenhead, May 28. G. W. WORRALL.

RELATIVE COSTS OF GAS AND ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The "Journal of Gas Lighting" refers to a recent article in your paper upon gas lighting. May I trespass upon your space to reply to the remarks of the "Journal of Gas Lighting"?

The writer of the "Memoranda" column in the "Journal of Gas Lighting" asks for figures giving the relative costs of gas systems against arc lighting. Unfortuantely, he requires these to be submitted with "gracious and valiant compliance." I fear I cannot compare in grace and valour with the article criticising electric lighting, but if the writer will excuse this portion, I am most pleased to submit a few extracts for his preliminary examination.

I should like to take this opportunity of noting the courtesy that usually marks the "Journal of Gas Lighting." A specially marked copy was duly sent to me, although it was needless in this instance, as I have for some time past regularly read the "Journal of Gas Lighting" with interest. The lamps mentioned by the "Journal," "giving an efficiency of 60 candles per cubic foot of gas," are the ones I should like to take for comparison. In this connection, Mr. Herring's figures of the Scottish National Exhibition are usually quoted by gas people. His highest reading gives an efficiency of 73·6 candle-hours per cubic foot, the candle-power being taken at an angle of 20 deg. below the horizontal. Prof. Morris, on testing these lamps, found an efficiency of 48 mean hemispherical candle-power at the maker's works, which fell to 31·6 and 27·5 when tested on East London gas. (*See* "Illuminating Engineer," Vol. I., p. 630.) Mr. Bradley, in his report to the City of Westminster, gives figures varying from 38·4 to 23·6, the candle-power apparently being taken at 20 deg. to 50 deg. below the horizontal.

Prof. Morris, in his comments upon the tests, said: "What do we find it does in actual practice? The above tests show that the maximum candle-power of the lamp is in one part of London about 800 candles, but take it to another part of this city and it yields 1,250 candles, and take it to Edinburgh when it will probably yield some 1,500 c.p.; truly a most disconcerting state of affairs." I quite agree with Prof. Morris. Does the 60 candles per cubic foot usually run down to 30 in actual practice?

I do not think I need add more details of victories of electric light over the latest forms of gas, as, in the same "Memoranda" columns, it is noted that Hampstead, Harrogate and Yarmouth are changing to the latest forms of electric lighting. Surely three victories chronicled in one issue of a paper will suffice for the moment! I regret that it is not our practice to publish beforehand where the Regenerative lamps will be installed. The "Journal" will soon have opportunities of seeing the localities lit by the Regenerative arcs that have displaced high-pressure gas.—I am, &c.,

A. DENMAN JONES, Manager.

Holloway, May 30.

SWITCH AND TRANSFORMER OILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Replying to my letter of the 10th inst., Mr Pollard says "Mr. Southcombe's assertion that I claim that alkali in a transformer oil would not be detected by phenol phthalein when the oil was shaken up with water is not warranted by any statement of mine."

Now, my reason for entering into this correspondence is to be found in Mr. Pollard's remarks, in replying to the discussion, "that at least 80 per cent. of the oils examined had been found to contain alkali, sometimes in slight and sometimes in very distinct traces, but had phenol phthalein been used as an indicator no doubt practically the whole of these would have been returned as neutral."

Such a statement cannot be allowed to pass unchallenged, and, as the following evidence will show, my assertion that "exceedingly minute traces of alkali, whether existing as carbonate, soap, &c., can readily be detected by phenol phthalein when the oil is shaken up with water" is strongly supported by other investigators.

The following experiments have been conducted at Liverpool University by Mr. A. B. Harris: A N/100 solution of sodic carbonate (Na_2CO_3) was made up with pure distilled water (specific conductivity $3{\cdot}1 \times 10^{-5}$ reciprocal ohms). Aliquot parts of this solution were diluted with the pure distilled water to varying concentrations of Na_2Co_3 and tested in open test tubes with three drops of phenol phthalein.

The following gives the results obtained: N/4,000 Na_2CO_3 solution (0·00013 gms. Na_2Co_3 in 10 c.c.), very distinct persistent colour; N/6,000 Na_2CO_3 solution (0·00008 gms. Na_2CO_3 in 10 c.c.), very distinct pink, persists for 12 hours; N/7,000 Na_2CO_3 solution (0·000075 gms. Na_2CO_3 in 10 c.c.), quite definite pink even after one hour; N/10,000 Na_2CO_3 solution (0·00005 gms. Na_2CO_3 in 10 c.c.), distinct colouration.

With ordinary laboratory distilled water treated in the same way as in an oil test I obtain distinct indications with N/5,000 solution (0·0001 gms. Na_2CO_3 in 10 c.c.).

Further, Glaser ("Indikatoren," p. 100) points out that even "the purest bicarbonate reacts weakly alkaline to phenol phthalein in aqueous solution."

With regard to the researches of Thomson, quoted by Mr. Pollard, in which he says that phenol phthalein is not a suitable indicator of alkalinity "when soda exists as hydrate along with sodium carbonate, &c.," I should like to point out that they do not materially influence this argument, since Thomson concerned himself with the sharpness of the end-point in titration and not with the qualitative detection of alkali. Again, Mr. Pollard appears to forget that when an oil containing soaps or alkali salts of petroleum acids is shaken with water the acid product of hydrolysis is continually removed by the oil, in which it is soluble, thus permitting hydrolysis to proceed almost to completion with the concomitant liberation of its alkali which dissolves in the water.

The results of Wright and Thomson refer to somewhat different conditions. As to the delicacy of phenol phthalein towards free alkali hydroxide, it is only necessary to point out that Dupré, quoted by Lunge (Tech. Methods), finds cochineal to be "*almost* as sensitive as phenol phthalein."

Mr. Pollard's conclusion, that "when phenol phthalein is used as an indicator considerable traces of alkali escape detection," is therefore not quite confirmed by the above-named investigators and my own experience.—I am, &c.,

Imperial Oil Works, Salford, May 27. JAS. ED. SOUTHCOMBE.

TEMPERATURE COEFFICIENT OF COPPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your remarks on the above subject, appearing under "Notes" in your current issue, do not necessitate any alteration in my letter of May 14th. My original letter can be supplemented by the following:—

1. You state that I start off with logarithms *which can be dismissed*. In answer, I point out that it is the E.S.C. who recommend such coefficients, and if logarithms are dismissed then resolution No. 4 becomes *absolutely meaningless*; this point is admitted in your remarks, for you find it necessary to add to the resolution in question the words "in terms of the resistance at 32°F.

Digitized by Google

2. The standard temperature for all ordinary commercial resistance measurements is 60°F. (75°F. for submarine work), and in view of this fact the E.S.C. considered it necessary, and have deliberately corrected to 60°F., the standard values of resistance of copper from Matthiessen's bases at 32°F. to form their resolutions Nos. 1 and 2; how then can you assert that it is plain that the E.S.C. "imply" (your use of this word seems regrettable when dealing with standards) a temperature of 32°F. for their resolution No. 4?

That 60°F. is the basis of tables of coefficients follows naturally from the fact that 60°F. is the standard temperature.

3. Cases are known in which engineers have had to insist, against their common sense, upon the use of the coefficient 0·00238 per degree difference from 60°F. simply "because the E.S.C. resolution reads this way."

4. The *universal* adoption of 32°F., as stated by you, is incorrect; *e.g.*, the Verband Deutscher Elektrotechniker recommend the formula $R_t = R_{15}\{1+0{\cdot}004(t-15)\}$ for copper, from which it will be seen that 15°C. (practically 60°F.) is the basis, and the coefficient is also much lower than that determined by Messrs. Clark, Forde and Taylor.

In conclusion, I greatly regret to find your remarks so personal towards the end—a mistaken help for a weak argument.—I am, &c.,

F. O. HOWE.

Old Charlton, Kent, May 28.

[In regard to the first three points raised by Mr. Howe we need add very little to our comments of last week. In our remarks we referred to submarine cable measurements, not to ordinary resistance measurements. If Mr. Howe and other engineers use a coefficient "against their common sense," they might at least use their common sense to be certain that they have not made wrong assumptions in applying that coefficient.

Mr. Howe's last statement is that the Verband Deutscher Elektrotechniker coefficient of 0·004 per degree C. (or 0·002222 per degree F.) referred to 15°C. (or 59°F.) is much lower than that of Messrs. Clark, Forde & Taylor. As explained in our last issue the latter is 0·00238 per degree F. referred to 32°F. (a fact which Mr. Howe can verify by purchasing Messrs. Clark, Forde & Taylor's pamphlet on "The Temperature Coefficient of Conductivity Copper," if he so desires) and is that adopted by the Engineering Standards Committee; it is a mean figure for commercial purposes. Now, if the resistance at 32°F. is taken as unity, that at 59°F., according to Messrs. Clark, Forde and Taylor's coefficient, is $1+0{\cdot}00238\times 27$, or 1·0642. Thus the variation per degree at 59°F. is 0·00238 in 1·0642, which gives a coefficient of 0·002236. This is practically the same as that of the V.D.E. In fact, the V.D.E. coefficient is only 0·63 of 1 per cent. lower than that of Messrs. Clark, Forde and Taylor, and in calculating a change produced by 30°F. the difference in the results by the two coefficients will be about 4½ parts in 10,000. This being so, it is surely rather an exaggeration on the part of Mr. Howe to describe the V.D.E. coefficient as being "much lower" than that of Messrs. Clark, Forde and Taylor. It is evident that for commercial purposes the V.D.E. coefficient is the same as that of Messrs. Clark, Forde and Taylor, and, therefore, necessarily the same as the E.S.C., so that Mr. Howe has scarcely chosen a good example to advance his case.—ED. *E.*]

THE ELECTRIC DRIVING OF PRINTING PRESSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Considering the grave danger to life and limb involved in a defective system of press driving, I think some protest ought to be made against the article from the "Electrical World" as abstracted in your issue of the 27th.

I do not think any manufacturer (on this side of the Atlantic) with a reputation to maintain would propose to his customers such a scheme as that outlined in the article, but there is a danger that the non-electrical customer should insist on some such cheap and shoddy arrangement, bringing in the end discredit on electrical driving in general.

Briefly, the author's scheme is to use two standard motors, one for starting and slow motion, and the other for ordinary working at full speed. These are to be operated by two standard controllers—that for the former motor having an armature diverter resistance added, that for the latter being provided if desired with dynamic brake contacts and a push-button stopping device. As the apparatus is spoken of as "standard" it is presumably legitimate to assume that no further "extras" are contemplated.

The most obvious defect is the provision of *two* handles, which at best is objectionable, but becomes positively dangerous when they are neither mechanically nor electrically interlocked. The ordinary press hand is a skilled man in his own particular work, but he does not know much about controllers. At a time of "rush" (when accidents most often occur) his attention will be chiefly concentrated on the press, and there will be great danger of his making a mistake with his two handles.

If he starts on the wrong motor he will probably have someone's fingers off. If he forgets to switch off the starting motor when done with, it will carry on the press when the main motor is switched off—perhaps for an emergency stop. The result in this case will probably be a bad jam of torn paper before the mistake is noticed.

With regard to the apparatus proposed, I noticed no mention is made of the "free-wheel" or disengaging clutch necessary in the drive of the small motor. Nor is it mentioned that ordinary starters, unless very substantially designed, have always proved unsatisfactory for the very heavy work involved in press driving.

Finally, with regard to the diagrams given, it will be seen that the armature diverter is arranged in the most inefficient manner, being placed straight across the mains when the small motor is full on. Further, the control of the main motor is all, or nearly all, effected by means of main resistance.

Recent practice has been all in the direction of increasing the proportion of field control given, one recent specification, for example, calling for as much as 3 to 1 speed variation by shunt regulation alone.

In any rotary press equipment, the cost of the whole electrical portion is very small compared with the total outlay, and still less compared with the possible cost of a breakdown, and it seems a pity that make-shift arrangements like that refered to should be seriously proposed.—I am, &c.,

Norwich, May 31. S. E. GLENDENNING.

TRAMCAR METERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see that in your notice of the new Siemens tramcar meter you say that "attempts were made in the early days of tramcar development to utilise ordinary meters for the purpose of recording the energy consumption of tramcars." I fear that the inference would be that ordinary meters have failed for this purpose. I should be allowed to state that, with my meter, owing to the extreme lightness of the armature, I have never experienced the smallestdifficulty when using it on tramcars, and I venture to think that there is a greater number of these meters so used than of all other types put together. I notice the means Messrs. Siemens have adopted to overcome the difficulty caused by a heavy armature; mine is so light as to avoid it altogether.—I am, &c.,

Birmingham, May 31. GEORGE HOOKHAM.

Power Required by Telephone Systems.—The "Engineer" gives some information with regard to the service of the New York Telephone Co., which indicates that the handling of a million messages requires on an average the expenditure of electrical energy to the extent of 900 kw.-hours. Assuming a heating power of 13,900 B.Th.U., it may be calculated that the development of 900 kw.-hours requires 2,025 lb. of coal. Allowing for sundry power-house wastes, perhaps it would be permissible to consider an English ton as the amount actually required in practice. The telephone messages of the United States now aggregate 9,000 millions per year, so we may set down the coal required for transmission at 9,000 tons. Of course, this is only a small fraction of the tonnage required for heating purposes in the 50,000 telephone exchanges.

HIGH-TENSION SWITCHGEAR,*

BY A. G. COLLIS.

Summary.—The author discusses recent practice in switchgear design and illustrates typical installations. In connection with switch construction, he describes a hand-operated, non-automatic, 3-pole oil switch. Instruments and the protection of circuits are also referred to.

When considering the design of a switchboard the following practical points should be remembered: (1) Simplicity, consistent with adequate protection, avoiding as far as possible the addition of unnecessary links. (2) Ease of operation and inspection. (3) Instantaneous response to the call of its duties. (4) Apparatus at high potentials placed in cells that will not, in case of fire, affect remaining gear, and arranged so that each respective gear can be inspected from the exterior, and isolated from "live" condition. (5) Inflammatory material to be avoided as far as possible. (6) Connections well spaced, to avoid short-circuits. (7) Only low-tension connections and indicators to be on the operating board and traceable at sight. (8) Liberality of design to withstand the development of abnormal conditions. (9) Sound earth connections.

The constructive portion of the board is materially affected by the space available and the conditions of service. When space, however, is limited, as at sub-stations, the design shown in Fig. 1

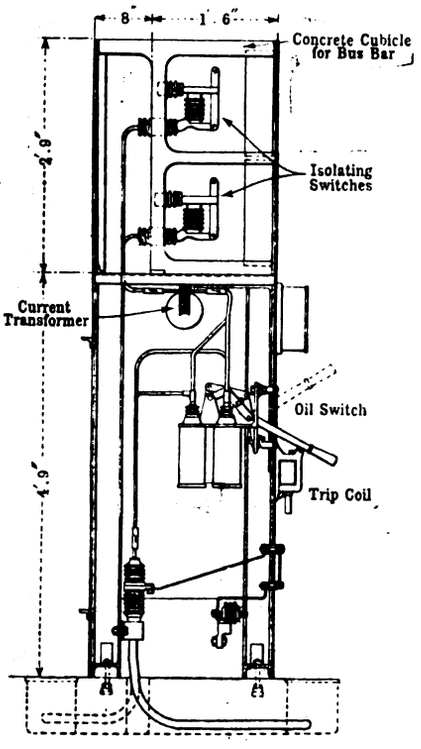

FIG. 1.—TWO-PHASE BOARD FOR 3,000 VOLTS.

will commend itself. This board controls three transformers and seven circuits at two phase 3,000 volt 50 frequency, the outer conductor being earthed. The author is personally in favour of this type of board, which may be described as "Ironclad type." It not only incorporates the points referred to above, but as iron constitutes the main construction, there is less danger, the iron being at earth potential, than with a board that consists of stone or other insulating material, which is never free from conducting mediums, such as slate with metallic veins, and stone with porosities which are hygroscopic; and, further, in the case of heavy cell fires or violent ruptures, the iron lends itself to displacement in a better manner than solid stone partitions, which could cause sonsiderable damage to their adjacent gear.

This type of board may not be adaptable for controlling units and feeders of a large central station, and for this work I prefer electrical remote control, similar to that fitted in St. Andrew's Cross Station, Glasgow. Fig. 2 shows a sectional view of this gear. This board is designed eventually to control six three-phase generators at 6,500 volts, 18 feeders, and two inter-connectors. It will be seen that the whole of the high-tension gear is situated in an adjacent room in separate compartments, and operated from the control board fixed on the gallery. Iron doors to admit of inspection of cells are shown, but preference has latterly been given to doors of uralite, which material is much lighter to handle, and is considered more in keeping with the cell structure. Another type of this class of board is shown in Fig. 3, and although I have stated I prefer electrical remote control, mechanical remote control has many advantages peculiar to itself, possibly due to space limitations, or, further, the switches being of such dimensions that the control board may be of the same width as the switch cells, without being of unreasonable length, with the additional advantage of a direct connection of each separate section. The board illustrated controls plant generating three-phase current at 6,600 volts 50 periods, and is of the "Bench type" construction, which design is very convenient, as it places the engine room in full view of the operator, this practice being almost universally adopted in power stations where the switchboard attendant is in command, controlling both the mechanical and electrical sides. At one of the largest stations in this country this method of control has been adopted, with very efficient and economical results. The success of such a scheme as this would, of course, depend largely upon the man in charge, and would probably result in disaster if the scale of wages were not increased, with the responsibility above the reported standard. I am led to understand that many of the reported failures of switchgear are due to the tendency of to-day to have cheap labour on improved systems; and, further, the tendency to place orders with the lowest tenderers not only discourages science, skill and design, but causes the omission of a large amount of actually necessary gear, resulting in breakdowns and fatalities. The author emphasises these points by quoting from the 1908 report of H.M. Inspector.

All circuits should be fitted with isolating switches, or so subdivided as to admit of attention while the section is dead, each section or circuit being in a separate compartment to prevent accidental contact with the adjacent "live" portions during repairs or inspection. Some engineers pay particular attention to this, and their ideas are further advanced by the additional precaution of inter-locked gear, so that it is impossible for a man to enter the compartment unless the circuit is dead. In many cases of electrical supply undertakings isolating switches are inserted on the 'bus bar side. This, however, does not mean that when these are in the "off" position the circuit is dead, as in the case of feeding in duplicate to a sub-station, the cable may be charged via the sub-station, which necessitates isolating switches being installed on that side of the oil switch. All isolating switches should be operated by an insulated rod or hook, and should be so mechanically constructed to resist twists as to ensure good contacts; also, if possible, earth contacts should be provided. It is preferable, in the case of a three-phase supply, to have single-phase isolating switches, as the coupling up of these switches may, owing to breakdown of insulation, place a "short" across the system, by no means an uncommon occurrence. Further, if the scheme is on a large scale, it should be sectionalised by 'bus bar switches, and this fact should be remembered by the operators. The observance of this might have minimised the extent of the disaster at Lot's-road, where the custom of running the whole station in parallel resulted in a complete shut down. Ring and duplicate 'bus bars and change-over systems have also their advantages, the design being regulated according to the conditions of the service, and the results aimed at by the supply authorities. Connections between gear should be "bare," not "insulated," in order to avoid inflammatory material, and should be cemented in porcelain sleeves when passing through partitions. All connections should preferably be clamped or coned, instead of, as is often the case, bolted or set-screwed, which causes considerable heating from imperfect contacts.

In connection with the foregoing alternating-current design, oil switch construction is exceptionally prominent. Many forms and types are now on the market, owing to the varied conditions of service, and the diversity of opinion amongst experts as to the proper form of design, more particularly on such points as the "disposition of the arc," "insulation," and "strains from explosive effects." It is necessary, however, that all these points should be incorporated, as the specialised application of one with the non-observance of the others may result in entire failure. Unfortunately, no definite data are available as to what is the breaking capacity of any switch, experience only proving that this or that form has successfully discharged duties which may, under different conditions, be totally inadequate for the purpose.

In order to demonstrate some useful points which I emphasise with confidence, I would refer you to Fig. 4, which illustrates a hand-operated non-automatic three-pole oil switch, capacity 100 amperes, at 6,600 volts pressure. It has a double break of 4 in. per pole (8 in. per phase), which length of break is consistent with its other capabilities of rupturing capacity, and for this size a smaller break is not recommended. The operating levers are fixed rigidly to the con-

* Abstract, from the "Transactions," of a Paper read before the Glasgow Technical College Scientific Society.

Digitized by Google

tacts and move in a vertical plane. The disturbance of the oil due to the arc is thus concentrated in the same direction, and not distributed over the entire area of the oil as in other forms. The position at which the arc takes place is near the surface of the oil, at which point it is free from the sediment which is found towards the bottom of the can, where the insulation value, owing to these impurities, is proportionately less. Further, when the rupture takes place near the surface of the oil, the pressure due to the explosion of the arc is relieved by the bubbles of gas passing into the air, the dielectric strength of the switch is therefore maintained. To obtain further efficiency in dealing with "strains from explosive effects," the oil cans are lined with three-ply impregnated wood, between which and the can there is a space of $\frac{3}{8}$ in.; this not only further increases the dielectric strength, but effectively damps out the arc on rupture, the oil in this space being in a quiescent condition. This is an important point, as burning oil and failure from strains may cause heavy fires, resulting in the complete shut down of a power supply. Each phase or pole of the switch is in a separate tank, thus admitting of the inspection of a single phase without removing the tanks of the whole switch, and, in addition, is much lighter to handle. The effectiveness of the switch, again, is increased by these divisions, it being practically impossible for the arc to form between the phases, there being a possibility of this occurring when all the phases are placed in one can. The contacts are brush type, fitted with additional sparking tips, which deal with the final arc on breaking circuit. I have always advocated this type of contact except when it is mechanically unheavy currents. Instantaneous rupture is essential for dealing with short-circuits, and it will be noticed that the pressure in the brush type is in a direct line with the operating mechanism. Immediately the toggle is released it assists the instantaneous action, whereas in the case of a "wedge" type contact the pressure is in a direction diagonally to the toggle, and may, due to guide friction, give a total frictional resistance more than equal to the weight of the switch, thus holding it in after the toggle is released, with disastrous results. The porcelain sleeves shown are of the corrugated type, which are now superseded by the straight pattern, for the reason that they are much easier to clean, and less liable to collect dirt or semi-conducting matter. The reeded type was designed originally to increase the leakage distance with minimum space; practice, however, proves the reverse.

Vitrified porcelain, which is specially moulded and treated by several processes, such as glazing and extra firing, in order to withstand excessive electrical pressure, appears to be still to the front for this kind of apparatus as an insulator. It generally consists of

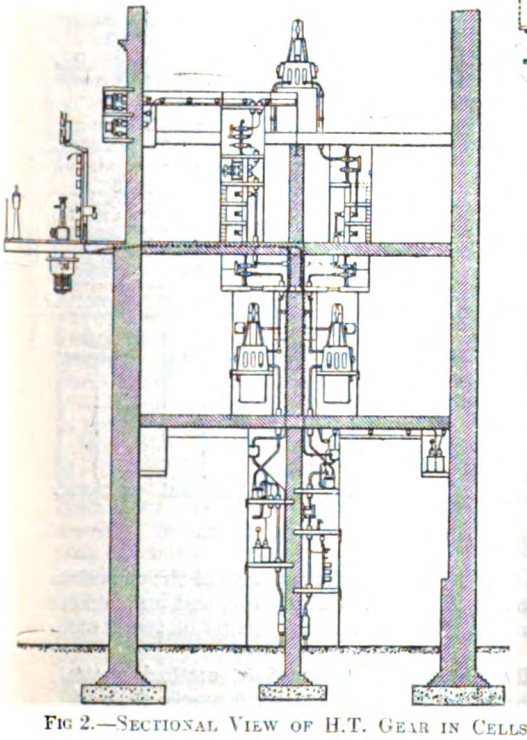

Fig 2.—Sectional View of H.T. Gear in Cells.

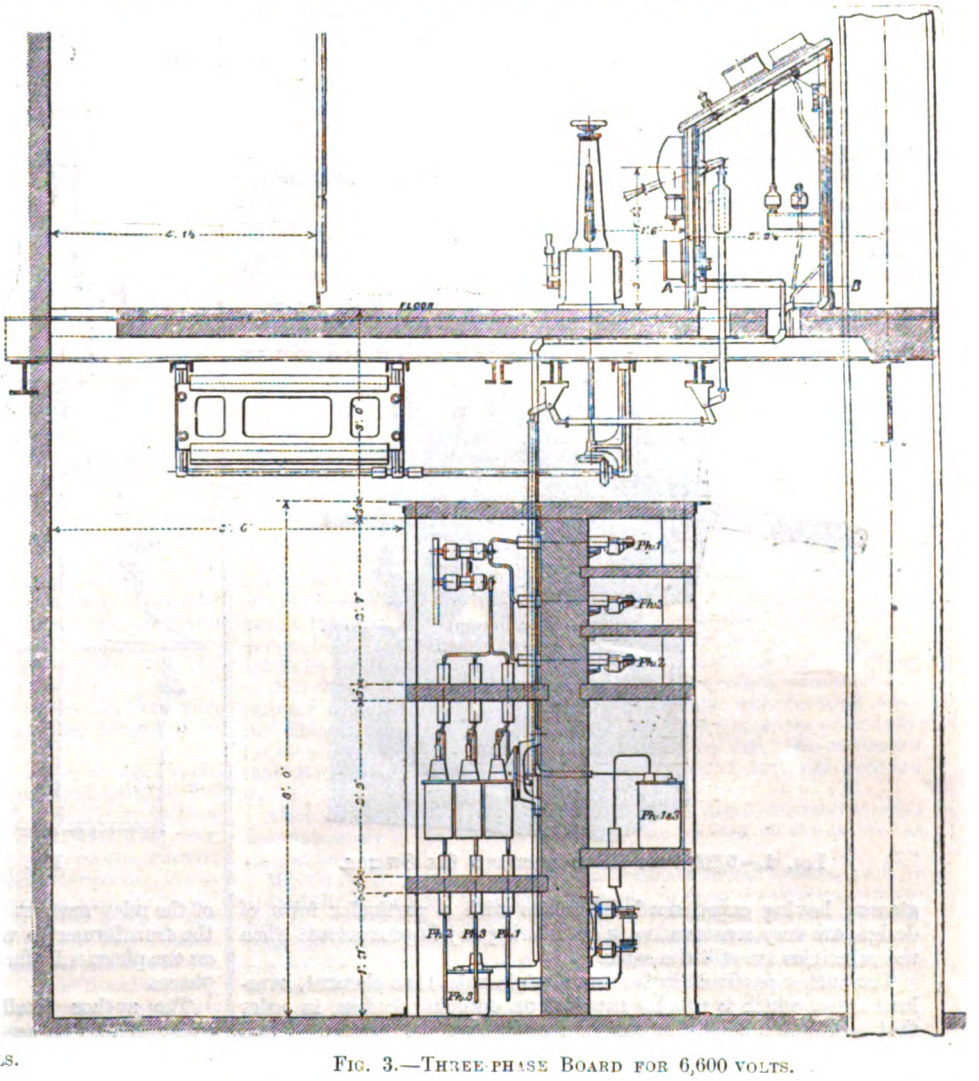

Fig. 3.—Three-phase Board for 6,600 volts.

desirable, for the reason that a brush or laminated contact, operated in the manner before described, has a self-seating position, rubbing away injurious surface films, and has the additional advantage of solid pressure without strains on auxiliary springs, and it also admits of a large contact area in proportion to its designed current-density. Tests show that a laminated contact will successfully rupture a much heavier current that a solid contact of the same sectional area at a lower temperature, and have also proved their superiority, as the contact area should not only be proportional to the sectional area, but also to the pressure. The contact area of a bar of copper (unlaminated) must be approximately five times the sectional area of the bar, with 25 lb. pressure per square inch, to have the same solid conductivity. The increase of the pressure to 35 lb. per square inch gives the same result with a contact area of only 4·2 times the sectional area. It will be noticed, however, that the contact area does not vary inversely as the pressure. The question of pressure must not be disregarded as affecting contact voltage drops. Contacts designed of the "wedge" or "cone" type are not usually the best practice, but are necessary in some cases for mechanical reasons and "kaolin," "felspar" and "quartz," the combination of which, after being properly fired, produces a crystalline silicate which only requires glazing to make it capable of withstanding the most severe potential strains. Apparently no other form of insulator has yet been designed to equal its effectiveness.

The above comments deal principally with the material of the switch. Lastly, but not the least important, is the mechanical construction. This construction must be of such movement that it will minimise shock, and also the manual effort in closing. It must be of parallel motion, and have a simple link construction. It will be noticed from the illustration that the handle operating the switch has a vertical movement, which places the operator in full command over it. When dealing with large capacities and heavy units, it should be noted that the mechanically operated remote control switch has many undesirable features, which have led to the electrical control type. On large power systems in America the motor operator switch is used. This is, however, not so efficient as the standard solenoid type, in which complicated mechanism and gearing, magnetic clutches, &c., are entirely eliminated, whilst it occupies

Digitized by Google

less space and operates more nearly instantaneously. In order to render the electrical control switch (Fig. 5) more efficient, a controller is advocated to operate it. This not only serves the purpose of making it "fool proof," but also places the auxiliary contact-making and breaking devices, &c., in an accessible position, apart from the main switch. A switch of this type should be designed—apart from its rupturing capacity and the general principles involved in the mechanical type of switch—so that it will operate with certainty and decision, and without any tendency to overshoot in closing, or rebound in the open position. It must not be possible for the operator to hold the switch closed under overload or short-circuit conditions, or to check or reverse its motion in an intermediate position, as hesitancy might be serious. This switch fulfils all these conditions.

The author next considers some points in connection with instruments, describing the main features of a few types, and then passes on to discuss the protection of circuits. On the boards previously described the system of protection is "reverse relays" on generators and overload relays on feeders. This form of protection is very universal throughout the country, and, as far as can be ascertained, is giving satisfaction. At one time plunger relays and differentially wound coils were very much in use, but owing to their ineffectiveness, principally due to "mechanical" and "floating" troubles, regardless of their electrical efficiency, these designs are practically obsolete. The differentially wound coil proved defective on account of the fact that short-circuit conditions reduced the power factor and voltage to such a low value that the relay did not develop sufficient torque to operate, and, further, it was impossible to use it for synchronising, as it did not cut out on reverse power, but acted on the synchronising or wattless currents, thus cutting out the very set that was normally correct for closing. Without altogether condemning this form of protection, I would like to add that, although experts have made considerable improvements in the detail of design, I find that en-

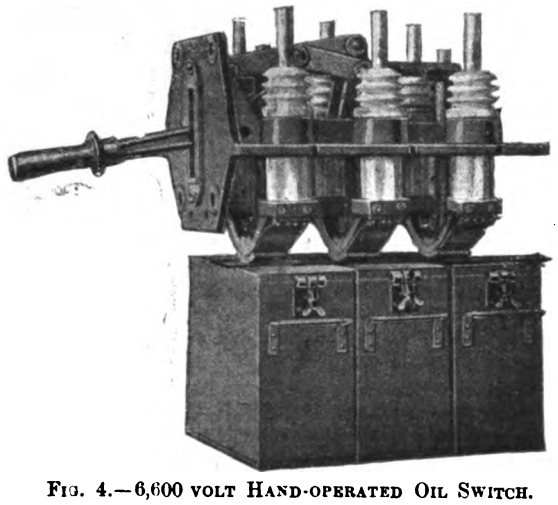

Fig. 4.—6,600 volt Hand-operated Oil Switch.

gineers, having experienced difficulties with a particular form of design, are very conservative in considering any improvements when the principles are still the same.

The author particularly favours a triple-pole, time element, overload relay, which is usually supplied on outgoing feeders, in order that a selective condition can be installed on the system. These relays consist of a rotary disc which revolves in a shaded pole-piece—that is to say, copper rings are placed on the poles, and the current induced reacts on the magnetic circuit, with the result that torque is exerted on the copper disc. The magnet is energised from the low-tension side of a current transformer, and when the current has reached its predetermined value the disc rotates, thereby winding up a hanging weight, closing the trip coil circuit by carbon contacts, and operating the switch. In addition, there is a damping magnet provided, by which the time element can be varied, the motion of the disc thereby being retarded to its predetermined time setting. The advantages of this type of relay are many, not only on account of its electrical effectiveness, but to the form of construction, which admits of the time element being varied within its range independently of its current value, and vice versa, a point which must not be overlooked in order to meet selective demands. The time element has an approximately inverse action, and will open the switch more quickly under normal conditions, which is very necessary. In order to meet competition and the demand for cheap gear, the time element on a feeder is provided in the form of a fuse, which is connected in shunt to the trip coil circuit. Owing to the high reactance of the trip coil the current normally passes through the fuse, but when it reaches the value the switch is set to open at the fuse blows, and the current then passes through the trip coil circuit, operating the switch. A fuse, however, has many disagreeable points, inasmuch as the time element cannot be changed without altering the current element, and although it has an approximate inverse action, there are no selective attributes.

There are several methods of "connecting up" relays and trip coils for protection against overloads, and the tendency should be to provide reliability with a minimum amount of gear, as additional links are a source of danger. Two overload trips with two current transformers will protect a three-phase system with neutral not earthed, or, further, two current transformers with one trip coil will be effective, the current in one phase being equal to the vectorial sum of the currents in the other two. Of course, protection in each leg further advances the degree of safety, but is not absolutely essential. With regard to protection on a three-phase circuit with earthed neutral, this can be met by having three current transformers and three trip coils. Preferably, it is a much better practice to instal three current transformers and two trips. With three transformer used in connection with two trip coils, the transformers would be connected in Z (*i.e.*, similar to a delta connection with the common transformer reversed), there being an advantage in using this connection over that of the straight delta, as in the latter each element

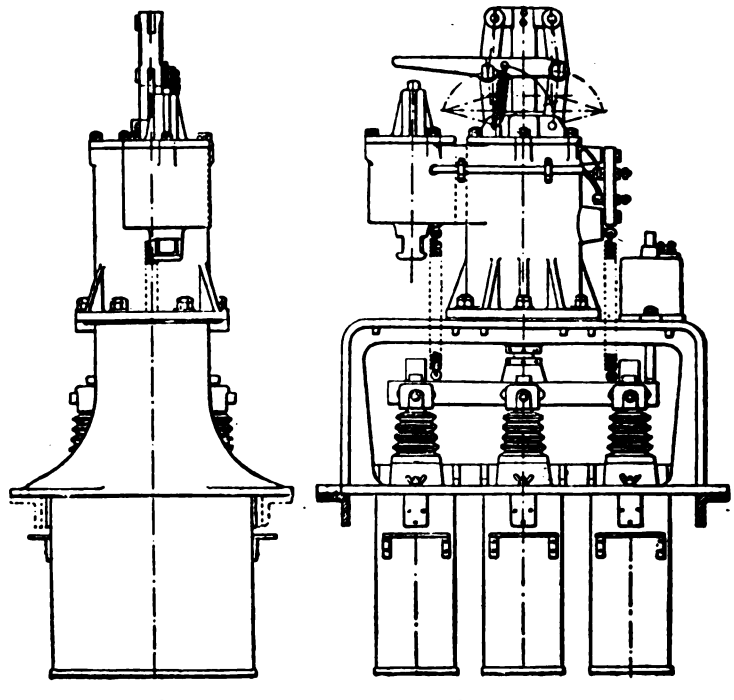

Fig. 5.—Electrical Control Switch.

of the relay receives current, which is the resultant of the current in the transformer to which it is directly connected, and an overload on one phase will affect the relay less than an overload on two or more phases

The author finally discusses the case of an earthed neutral, and describes an appliance which apparently effectively deals with the safety of an earthed neutral by means of a ring transformer, the principle being as follows: Consider a generating station, from which a number of high-tension three-core cables diverge, feeding separate areas. If there be no earthing on any particular feeder, or on the network connected thereto, the sum total of the currents in the three cores must be zero at every instrument, and this is true independently of whether the load is balanced or not. If, then, the feeder cable be surrounded by the magnetic circuit of a ring type transformer, there will be no total magnetisation in it. Now, although no point of the system is connected to earth, there will be a certain capacity current flowing to earth at any instant from any two poles, say A and B, which must equal the capacity current flowing from earth to the third pole C, at that instant via the dielectric. Suppose, now, there be an earth anywhere on pole C, reducing this part of the system to earth potential, the capacity current to earth from A and B must find its return path through C; but since C is at zero potential, the current cannot be passing via the dielectric, and consequently the whole capacity current must pass from earth to pole C via the fault; in other words, if we had 20 healthy feeders and one faulty one, with an earth on one core, the capacity current flowing to earth from the 20 healthy feeders would be restricted in its return path to the faulty

Digitized by Google

one. Let us take it that the strength of this capacity current is 30 amperes. Then the induction of the magnetic circuit round the faulty cable will be due to 30 ampere-turns, and will be quite independent of the load on the feeder, while the induction in the transformer cores of the healthy feeders will be on the average due to 1·5 ampere-turns, the total capacity current being supposed to be equally divided among the 20 feeders. A ring type transformer of the type referred to can readily be designed to operate a relay with 30 ampere-turns primary current or even less, and this relay may in turn operate an indicator, or alarm, or close the trip coil circuit of the circuit-breaker. We should thus have a protective arrangement applicable to any extensive distribution with unearthed neutral, whereby any cable would be automatically disconnected should a core go to earth, and this without any rush of current and consequent disarrangement of the system.

We should arrive at the same result in a system of much smaller capacity by connecting the neutral point to earth through a relatively high resistance—viz., one capable of passing, say, only 30 amperes if a pole became earthed. There are many advantages in a high resistance of this order, besides that of cutting off the faulty feeder without excessive current rush. For example, the avoidance of interchange of current between generators working in parallel due to triple frequency terms in the E.M.F. wave; the relatively small size of the resistance required, &c. Complete protection would be afforded by current transformers inserted in any two of the phases with a ring type transformer surrounding the whole.

DISCUSSION.

Mr. CALDWELL said, in view of the very general trend of opinion to the contrary, it was interesting to note that Mr. Collis inclined to favour the use of reverse current protection for alternating generators, but the speaker was of opinion, owing to the unreliable action of this particular type of apparatus, that it was better to rely upon human protection. A large, healthy unit coming out on action of the reverse current relay, due to a wattless current, might mean the shut down of a station having only two or three sets. In a static transformer sub-station the case was different, as there was no attendant, and a faulty transformer must be cut out automatically and instantaneously, and reliable automatic apparatus to ensure this was very desirable. More attention should be given by designers of alternating switchgear to the reliability of instrument transformers. The frequent breakdown of these was a great nuisance, and potential transformers should be made larger in order to obtain a greater degree of reliability. With regard to oil switches for extra high-tension work, it was time designers entirely eliminated wood from this class of apparatus. In regard to facilities for making cable connections (particularly as to the conditions existing in coal mines, but applicable generally), in the best work armoured cables were employed, and there was no reason why the design of clamped rings to effect electrical continuity of the armouring should not be standardised. His remarks applied, of course, to isolated switchgear, such as oil switches, gate end panels and smaller motor panels. At present, even for the smallest item of such apparatus, cumbersome and expensive trifurcating boxes had to be employed.

After other speakers had expressed their appreciation of the Paper, Mr. COLLIS, in reply, said, in regard to reverse current oil switches for generators, he was aware that they had not fulfilled all the conditions attributed to them, and he thought the specified conditions were very extreme. He did not think it was possible to design a reverse current relay that would meet all the conditions Mr. Caldwell referred to. As to instrument transformers, most of the troubles referred to were due to the fact that, in order to get constant ratio at all loads, the primary and secondary windings were very close together, with a result that a short-circuit occurred between primary and secondary, and, as one side of the secondary was earthed, the primary went to earth. Additional security against this was an insulator, further surrounded by a core of stampings, on which was wound the secondary coil. Regarding cable runs for mines and for collieries, he differed from Mr. Caldwell owing to the difficulty of keeping the armouring of the cable from going to earth, due to the water and falling masses, together with the failing roofs, a direct connection might be formed between the cable and earth. In this connection he advocated that the armouring be supplied only for mechanical protection, and between it and the cores there should be a tubular core which was earthed at the pit bank. By interposing a coil in this circuit, should an earth occur the coil would be operated by the leakage currents and the section isolated before any external damage was caused, thus preventing the serious explosions referred to so frequently of late.

Tungsten Mining in Colorado.—According to the "Electrical World," the tungsten mining and milling industry has received a great impetus in Boulder County, Colorado, as a result of the improved methods of manufacture and the better prices obtainable. The Eureka Tungsten Mill has just begun operations, using a belt table arrangement of new design, and recovering a large proportion of the tungsten. The mill is a brick structure, and is entirely electrically operated.

LEGAL INTELLIGENCE.

City of Birmingham Tramways Co. v. Geo. Law.

Mr. Justice Lawrence gave judgment in this case on Saturday. Plaintiffs claimed for damages to a tramcar in Bristol-rd., Birmingham, in October, 1908, and alleged that one of their cars was derailed and damaged owing to the negligence of defendant, the contractor for the reconstruction of the line.

HIS LORDSHIP, in delivering judgment, said he understood the damages had been agreed at £421. 15s. 4d. in the event of plaintiffs establishing the liability of defendant. Only one line was in use at the time, the other being under reconstruction, and his Lordship said he had come to the conclusion that the derailment of the car was caused by the gearbox of the car coming in contact with one of the contractor's blocks, which had risen, that being due to the fault of defendants' servants. It was contended that defendant was under no liability to plaintiffs, because there was no contractual relationship between them, the Corporation owning the lines and the company being merely assignee of the lease of the tramway. Under that lease repairs were to be executed by the Corporation, but at the expense of plaintiffs. It was provided that the company should be able to continue the service during reconstruction, and the agreement imposed upon the contractor liability for any damages or injuries sustained while the work of reconstruction was in progress. Defendant, by that agreement, indemnified the Corporation, and plaintiffs were, therefore, entitled to judgment.

Wheeler v. Marylebone (London) Council.

The hearing of this case was continued on Friday last before Mr. Justice Grantham and a special jury.

Mr. JOHN LYNTON, assistant engineer to the Charing Cross, West End & City Electricity Supply Co., said he thought that a person holding the ends of the cable in question would receive a shock, but not sufficient to kill.

In answer to his Lordship, Mr. HOLDEN (with Mr. Shearman, K.C., for defendants) said the cables were on the three-wire concentric system, and the pressure between the outers was 480 volts. The pressure of supply was not more than 240 volts in any house. He had never known a case where a cable had been pot-ended and the dead cable left in the house. They always took away dead cable. He would not always remove a cable if the rebuilding operations were confined to the top of the house. He would not remove the cable if the housebreakers were not going to interfere with the cellars.

Mr. H. T. GORDON, architect and surveyor, said he always specified that all pipes should be removed from cellars or anywhere else when housebreakers were at work.

Mr. SHEARMAN, K.C., for the defence, explained that when the Council were notified that the housebreakers were going to commence work one of the Council's employés was instructed to "draw the service," which meant that the whole of the wires and cables in the house were withdrawn, but when he got to the house he was told that the cellars were not to be removed, so he simply shut off the current from the cut-off box in the cellar. That was perfectly safe, even if the cellars were used, and plaintiff did the only possible thing to cause trouble when he tried to cut it. They were sorry for him, but he suffered from a supreme act of folly, for he must have known that the cable was a live one. He contended that the Council had not been guilty of a breach of duty and were not liable.

After medical evidence, Mr. SIDNEY J. JONES, assistant meter reading superintendent in the Council's employ, said he shut off the service at the cut-out box.

Mr. CHAS. H. SMITH, constructional engineer to the Council, said he visited the house after receiving the request to draw the service, and was told by the foreman housebreaker that as the cellars, which were away from the house, were not to be interfered with, there was no need to remove the cable. He altered his instructions to the joiner, telling him to draw the service as far as the cut-out box and make that secure. The foreman told him that all he wanted removed was the meter and the appliances within the house. Referring to custom, Mr. Smith said, bearing in mind that it was a very expensive matter to meddle with or alter the service beyond the cut-out, the cables were left in their positions as far as it was consistent with safety, but in that particular case, had he known that the structure of the cellars was going to be interfered with, he should not have let the cable remain.

Mr. JOHN F. C. SNELL, consulting engineer, said the system of leaving a cable in a cellar such as the one in question, as long as the cellar was not to be interfered with, was universal. It was perfectly safe, unless cut or tampered with.

Mr. A. HUGH SEABROOK, the general manager of the Council's electrical undertaking, also gave evidence.

Mr. DUKE, K.C., for plaintiffs, said if the Council had done what was requested of them the accident would not have happened. Instead, in the hope of saving expense, only half of the work was done, and a live cable was left in a place where it was a danger to everybody on the place. Had they placed a switch in the service box under the pavement and right away from the house, and cut off the power at the switch, the cable would have been rendered harmless, and they would have saved the expense which they said would have been incurred by drawing the cable.

HIS LORDSHIP, summing up, said he thought that the Council had been guilty of a wrong in leaving the cable in the cellar without giving plaintiff notice.

Digitized by Google

The jury awarded plaintiff £56, special damages claimed by him, in addition to £75 for pain and suffering, and £450 for loss of business during his incapacitation.

His Lordship entered judgment for plaintiff, and refused an application by defendants for stay of execution.

Hire of Electric Motors.

In the Shoreditch (London) County Court last week, Judge Smyly, K.C., heard an action by Herr Julius Grevener (Attorney of the Sachsenwerk Licht u Kraft A.-G., lately trading in London as the Electromotor & Dynamo Co.) against Mr. Geo. Chamberlain to recover £49, value of an electric motor, and £1 damages for its detention. For plaintiff, it was stated that defendant was the owner of premises which he let to a tenant named Gover, who hired a motor from plaintiff Company, and defendant entered into an agreement that, in the event of an execution for arrears of rent, he would not seize the motor. The motor was, however, seized and subsequently sold.

KARL KOPECH, for plaintiffs, gave evidence as to the hiring of the motor by Gover, £59. 8s. 7d. being the amount mentioned in the agreement.

In reply to defendants counsel, witness said the Sachsenwerk, &c., Co. was a German firm carrying on business in England in July, 1909.

Defendant's counsel: By sec. 274 of the Companies Consolidation Act, 1908, every company incorporated outside the United Kingdom and trading therein must be registered, under a penalty of £50 and £5 for every continuing day of default. Has this company been registered in the United Kingdom?

Plaintiff's Counsel: I object to that question.

Judge SMYLY: I do not see how you can object, except on the ground that the company is not bound to incriminate itself.

It was admitted that the motor had been sold, so plaintiffs counsel said all he had to put his mind to was the price, and he then detailed the hiring prices, cash prices, the time the machine had been had, amount allowed for depreciation, &c.

The defence was that the value of the motor had been greatly exaggerated—the claim being for £49 and £1 as damages for detention.

Judge SMYLY, asked if the machine could be returned, and having been informed it could not, as it had been sold, said he could find nothing wrong with the claim, and there would be judgment for plaintiff for £50 and costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

A science master will be required in September at Huish Grammar School, Taunton, who is also qualified to teach electrical engineering and kindred subjects at the Municipal Technical Institute in the evenings. Salary £200 per annum, non-resident. Particulars from the head master, Mr. Arnold Goodliffe. See an advertisement.

An unmarried commercial assistant is wanted for a British electrical firm in India. Commencing salary £15 per month. See advertisement.

Applications are invited for the position of borough electrical engineer at Salford. Salary £500 per annum, rising to £700. Applications to the town clerk, Mr. L. C. Evans, by June 13.

Erith Council require a canvasser for their electricity department. Wages £2. 10s. per week. Applications by noon June 8.

The Council of the University of Manitoba, Winnipeg, Canada, require a lecturer in electrical engineering. Salary $1,500 a year. Applications to the Registrar by June 25.

Kent Education committee require an assistant master in the electrical engineering department of the Technical Institute, Gillingham. Forms of application from Mr. J. Thompson, Town Hall, Chatham, and applications to the Director of Further Education, Mr. R. L. Wills, M.A., Technical Institute, Gillingham, by June 20.

The Council of the University of Manchester require an assistant lecturer and demonstrator in the department of physics. Applications to the Registrar by June 13.

The professorship of physics at University College, Reading, will shortly become vacant. Particulars from the Registrar.

Sunderland Corporation have promoted Mr. J. A. Crowther (shift engineer) to the position of assistant electrical engineer, in succession to Mr. L. B. Humphreys, who has resigned.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, and the City and Guilds Technical College, Finsbury, are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years. The Finsbury College is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover a period of two years and those in chemistry three years.

University of Bristol.—The following have been appointed external examiners in the faculty of engineering:—

Civil Engineering.—Prof. S. M. Dixon, M.Sc., M.A., M.Inst.C.E. *Mechanical Engineering.*—Prof. W. Ripper, D.Eng., M.Inst.C.E. *Electrical Engineering.*—Prof. S. P. Thompson, D.Sc., F.R.S. *Mathematics.*—Mr. P. T. Wrigley, M.A. *Chemistry.*—Prof. S. Young, D.Sc., F.R.S.

Australasia.—The "Australian Mining Standard" states that a resolution was passed at the recent meeting of the Associated Chambers of Manufacture's, expressing disapproval of "the continued and growing interference by Government workshops with private manufacturers." There was only one dissentient vote.

Melbourne Electric Supply Co. has commenced the work of erecting cables for supplying current in Brighton (Victoria). High-tension underground feeders are to be laid to transformer pits, where the pressure will be reduced from 4,000 to 400 volts, the latter being transmitted by overhead distributors. The charges for current will be 5½d. for lighting, and 2d. for power, with a reduction to ¾d. for power after the first 1,000 units per month.

Leichardt and Petersham Councils have agreed to the erection of overhead transmission lines through their districts from the Sydney electricity works at Balmain to Newtown.

The net profit on the past year's working of the Wellington (N.Z.) tramways was £6,123.

Yarrawonga (Victoria) Shire Council are in favour of the provision of electricity supply for their district, if it can be done without putting an additional financial burden upon the public funds. Delegates have been appointed to visit towns possessing electricity works.

Austria-Hungary.—A 60-years' concession has been granted to Dr. H. Ofner for the construction and working of a light electric railway from St. Polten to Harland.

Birmingham.—The draft provisional order for the extension of the city has been issued and provides for the inclusion of Aston, Erdington, Handsworth, Yardley, and part of King's Norton and Northfield.

The tramway undertakings of Aston Corporation and of three Urban Councils are to be transferred and are to be worked and maintained by the Corporation. The electricity undertakings of Aston Corporation and of Handsworth Council, and the electricity undertaking of the Corporation of the existing city, are to be maintained and managed by the Corporation of the city as one undertaking, and the provisions of the Birmingham Corporation Act, 1899, which relate to the electricity undertaking of the Corporation of the existing city, and the provisions of part 130 of the Birmingham Corporation Act, 1903, will apply to the amalgamated undertaking. The prices to be charged by the Corporation for energy supplied by them to any consumer within Aston and Erdington must not exceed the prices charged by Aston Corporation on March 31, 1910, for energy supplied by them in the like circumstances. Within two years from the commencement of the order the Corporation must lay down distributing mains for general supply of electricity throughout every street within King's Norton and Northfield and Yardley.

Blair Atholl (N.B.)—About two years ago Blair castle was provided with an electric lighting installation, water power being employed in the generation of electricity.

His Grace the Duke of Atholl subsequently decided to supply electric current for lighting the village, the cost to be simply enough to cover the interest on the initial expenditure. On Saturday evening the first section of the public lighting was inaugurated, when current was switched on to the Atholl Arms Hotel by Mr. Macdonald. There are about 200 lights. The consulting engineer is Mr. W. H. Massey, whose assistant (Mr. Seth) superintended the general work.

Brighton.—At their meeting yesterday (Thursday) the Corporation were recommended to adopt a revised scale of charges for electricity for power, so that customers should pay 2d. per unit for electricity for power during the hours of peak load, subject to a two-rate meter being fixed.

The salary of Mr. G. Cloughton, power-house superintendent at Southwick works, has been increased to £300 per annum.

Cambridge.—The Council propose to have the Guildhall wired for electric lighting.

Church Lighting.—St. Matthew's Church, Bolton, is to be lighted electrically.

Digitized by Google

Committee for the Protection of Electrical Interests.—At a meeting of this committee on 25th inst., Mr. Robert Hammond presiding, Mr. Arthur Preece was elected hon. treasurer, and Mr. R. Borlase Matthews, who has acted as hon. secretary pro tem., was elected hon. secretary.

Coventry.—The Corporation have approved a recommendation of the Electric Light committee to increase the salary of the electrical engineer and manager of the electricity department, Mr. G. Tough, from £350 to £450 per annum.

The Electric Light committee recommend the following charges for electricity for power and domestic purposes other than lighting: For first 2,500 units per quarter charge to be reduced from 1¾d. to 1½d. per unit. Where consumption exceeds 50,000 units per quarter, a flat rate of 1d. per unit will be charged, and for energy for domestic purposes other than lighting 1d. per unit.

Derby.—The Tramways committee claim that the charge for electricity for traction should be reduced from 1½d. to 1¼d. per unit.

Eccles.—The Borough Treasurer has been instructed to transfer the profit on the electricity undertaking for the year ended March 31 (£1,206) to credit of capital account of the undertaking towards the excess expenditure for which the L.G. Board refused to grant borrowing powers. An offer is to be made to supply energy for power to the works of Messrs. H. Cardwell & Sons, Winton.

An unopposed inquiry was held last week into the Council's application for sanction to borrow £3,234 for extensions of the electricity undertaking.

Electric Railways in America.—An electric railway 49 miles in length between the island of Galveston, by way of a causeway, to Houston, on the mainland of Texas, is expected to be completed next year. The cost (apart from that of the causeway) will be about $1,500,000 (£312,500).

The New York-Boston Railway Co. is building a rapid transit electric railway from the Harlem River, through Westchester County, into Connecticut.

Electricity in Mining.—The new mill and cyanide plant of the Roodepoort United Co. (Transvaal), which consists of 100 stamps in sets of 10, are to be driven electrically.

Each set is driven by a separate motor, and the stopping of one set will not involve the stoppage of the whole mill. The first installation of tube mills will consist of five. There are seven shaking tables to each tube mill, each driven by an independent motor. Each motor can be transferred by gantry or crawl to the electricians' repair shop, so that repairs can be speedily and economically effected.

An electrically-driven Belliss compressor had been erected near the central shaft. The company derived part of its power from the Umtali Waterfall, in which it owned a half share, but that power not being sufficient, they had to lease power from the Odzani hydro-electric station of the Penhalona Proprietary Mines, about 7 miles from the mine.

At the meeting of Rezende Mines (Ltd.) on Tuesday the chairman (Mr. S. H. Farrar) said that the west shaft had been thoroughly equipped with an electrically-driven hoisting engine and electrically-driven turbine pumps.

Exhibition.—A colliery and mining exhibition is to be held at the City Exhibition Hall, Manchester, from June 16 to July 1, inclusive.

Fatality.—At the Glamorgan colliery yard, Rhondda Valley, on Wednesday a surface foreman named Edward Abbott came into contact with a live electric wire and received a fatal shock.

A hauler named Doel was driving a horse attached to two trams to a brickyard, when the animal came in contact with a live wire and fell dead. Doel, who held the leading chain, also received a shock, and fell on the horse. Running to Doel's assistance, Abbott leaned over one of the trams and also received a shock which proved fatal. Doel recovered.

Folkestone.—The Council have deferred for seven years the question of purchasing the undertaking of the Folkestone Electricity Supply Co.

Fulham (London).—The outstanding capital expenditure on the electricity undertaking at March 31 was £229,960. 4s. 1d.

The Borough Treasurer reports that the revenue from the sale of current was satisfactory, and showed an increase compared with 1908-9 The total revenue was £29,917. 14s. 7d., against £29,535. 15s. 3d.; total expenses were £25,351. 10s. 7d., against £25,962. 1s. 2d. The net surplus is £4,551. 6s. 5d., against £1,914. 10s. 11d. The number of units sold for private lighting was 2,202,287 (at an average rate of 2·5d. per unit), and showed an increase of 4·85 per cent., while the receipts showed a net increase of £717. 9s. 5d. Public lighting revenue showed a decrease of £325. 3s. 1d.

Glasgow.—At the meeting of the Corporation last week it was decided to increase the salaries of three members of the staff by £25 per annum. The salary of the inspector of lighting (Mr. S. B. Langlands) was also increased from £350 to £450.

Grimsby.—The Council have abandoned the proposal to hire out arc lamps, &c.

Haslingden.—At the last meeting of the Council Mr. Barnes complained that little progress had been made with the electricity supply question. There was a certain demand for current in the district, and the Electricity committee should take steps to satisfy that demand.

In reply, the chairman of the committee (Ald. Barlow) stated that negotiations were proceeding with a company for a supply of electricity in bulk and he hoped to be soon in a position to call his committee together to consider the question.

Holland.—Middelburg communal authorities have voted 1,250 gulden (£104) for obtaining information as to the practicability of establishing electricity works.

Hull.—The Electric Lighting committee have acquired a site in New George-street for a sub-station.

Hydro-Electric Works in Japan.—It is reported that the Imperial Government has decided to establish an office under the control of the Department of Communications to make inquiries as to the water power available for the generation of electrical energy in Japan. Seven branch offices will be established. The work will probably be started in September next.

Inquest.—An inquest was held on Wednesday into the death of Henry Colburn, who was killed at Newland Collieries, Normanton, Yorkshire, on Monday.

Colburn and three others were working an electrically-driven coal-getter. When the current was switched on Colburn, inadvertently put his foot on the steel hauling rope and received a fatal electric shock. It was stated that water had affected the insulation of an electric cable, and caused a leakage, the current passing through the rope. Wordsworth, who attempted to drag deceased away, also trod upon the rope and felt only a slight shock. He was wearing clogs, and the wood acted as an insulator. Deceased wore leather boots.

The collieries manager (Mr. J. Gill) stated that such machines had been daily used for 23 years, and no accident had happened before.

A verdict of death from paralysis of the heart, due to electric shock, was returned.

Kingsbury (Middlesex).—The chairman of the Council (Mr. Jose Daiz) stated at the last meeting that numerous letters had been received from people who were anxious to know when electricity supply would be available. Although they had received the help of Hendon Council, it was not possible yet to formulate a scheme.

Leeds.—On the presentation of the report of the Tramways committee of the Council on Wednesday a question was asked as to the purchase of 350 additional renewable joint plates, and the acceptance of tenders for fishplates. It was also asked whether it was intended to replace the Thermit welded joint.

The chairman of the committee (Mr. R. A. Smithson) replied that the renewable joint plates were in no sense a substitution for thermit welding, which was being applied to all new rails. They found, however, that fishplates were more suitable, from an economical point of view, for the old rails.

L.C.C. Tramways.—Southfields residents have requested London County Council to extend the tramway from Wandsworth to the county boundary at Southfields.

Marylebone (London).—On the recommendation of the general manager (Mr. A. H. Seabrook) the insurance of the plant at the generating station against breakdown is to be discontinued. The original risks insured against have now been largely removed, and Mr. Seabrook is not aware of any similar undertaking having this description of risk covered by insurance.

Metropolitan Asylums Board.—The actual cost of substituting metal filament for carbon lamps at the Board's institutions amounted to £1,880. 5s., against an estimated cost of £1,921.

Naval Electrical Engineers.—The Admiralty have issued new regulations for the appointment of electrical engineers and of first and second assistant electrical engineers at the Admiralty and in the Royal Dockyards.

Vacancies for electrical engineers will be filled by selection from first assistant electrical engineers, and vacancies for first assistant electrical engineers will be filled by selection from one or other of the following classes:—Assistant electrical engineers; dockyard employés who have held the Admiralty scholarship; outside candidates, who will be required to produce evidence of having passed through a course of engineering study in a University technical college, or other educational establishment, to the satisfaction of the Admiralty, and of having been engaged in practical engineering work for at least five years, part of which time must have been spent in a responsible position as electrical engineer. As a rule every second vacancy will be filled by the appointment of an outside candidate. Second assistant electrical engineers will be made by means of a competitive examination at which inspectors or electrical fitters and first-class draughtsmen of three years' seniority and persons qualified by Admiralty scholarship will be eligible to compete, provided they are under the age prescribed by the Home Dockyard Regulations.

An Admiralty scholarship in electrical engineering (£40 per annum) has been established for a period not exceeding six years, and will be awarded

Digitized by Google

to a specially able and deserving electrical fitter apprentice who has completed his four years' course of study in a dockyard school. The holder of the scholarship will be placed on the establishment as electrical fitter, and will proceed to the Royal Naval College, Greenwich, for a year's study in electrical engineering, at the end of which he shall, at the discretion of the Admiralty, continue to hold the scholarship for a second year. On passing satisfactorily at the conclusion of a two years' course at Greenwich he will return to service in a yard or at the Admiralty as supernumerary electrical draughtsman, and after one year's service will be eligible to compete for appointment as first-class draughtsman or inspector or second assistant electrical engineer in the event of a vacancy. He will further be eligible for selection as first assistant electrical engineer after not less then three years' service, subsequent to his Greenwich training. The first award of the scholarship will be made after the Dockyard Schools' examination this month, to the electrical fitter apprentice who has distinguished himself most highly in that examination or in the examination of the previous year.

Nottingham.—At the City Council meeting on Wednesday the Tramways committee were instructed to execute the works required for the Carlton road tramways, as soon as possible after the Corporation Bill had received the Royal assent. It is hoped to have the line completed by October.

Pakefield (Lowestoft).—The Mutford and Lothingland Council have been asked to consent to an application by a company for a provisional electric lighting order for this district.

Personal.—Mr. F. W. Hartmann, A.M.I.E.E., asks us to state that he is no longer actively connected with the Langdon-Davies Motor Co. (Ltd.), having resigned his position as assistant managing director.

Mr. Charles Bright, F.R.S.E., asks us to state that his appointment recently announced by the Australian Commonwealth is a home (London) appointment for partial services, and will not, therefore, as appears to have been supposed, take him to Australia.

We regret to learn that Mr. S. E. Fedden, manager of the Sheffield electric lighting department, is still confined to his house in consequence of an operation which he underwent two or three weeks ago.

Plymouth.—The borough electrical engineer (Mr. E. G. Okell) has been asked to report upon the question of letting motors on hire.

Printing, Stationery and Allied Trades' Exhibition.—An electrical engineer, visiting this exhibition, which remains open at the Agricultural Hall (Islington, N.) until June 11, cannot help being struck by the extended use that is being made of the electric motor for driving printing, composing and other similar machinery.

While the Agricultural Hall possesses its own steam plant and is willing to supply power to any of the stands, a large majority of the exhibitors do not appear to have taken advantage of these facilities, but have, instead, installed their own motors and have adopted the electric instead of the steam drive. Seeing what a large part printing and the allied trades play in our daily lives, it is not surprising that the engineering visitor will find much to interest him outside his own sphere.

The specimens of printed art, which are on view, may be justly called marvellous, and even the most casual observer cannot help being struck with the varieties of processes through which even the simplest piece of news has to go through before it can appear in the daily journals. The principal exhibit, from the electrical point of view, is to be found on Messrs. Harrild & Sons' stand, where Messrs. Electromotors (Ltd.) have a very complete installation of their motors and switchgear applied to the various printing and composing machinery to be found there. Other electrical firms represented are Messrs. Newtons (Ltd.), J. & H. Grevener and F. A. Glover & Co. The latter firm are also superintending the lighting of the exhibition.

Railway Signal and Telegraph Engineering Institute.—The last meeting of the session was held at Marylebone Church Institute on Monday. Mr. W. J. Thorrogood was in the chair.

Mr. F. W. R. May delivered a lecture on "Automatic Relays and Switches as applied to Telephone Installations." The lecturer also touched upon automatic relays for signal work.

A lengthy discussion followed, in which many of the members took part, after which the chairman gave an address, and hoped the movement for which the institute was established would continue to make progress equal to that which had attended its first season.

A vote of thanks to Mr. May for his lecture was carried unanimously, and a similar vote to the chairman for his services and the support he had given the movement from the start.

Richmond.—The Council have agreed to an extension of 12 months for constructing the tramway in the Kew-road as a single line, as proposed by the London United Tramways (Ltd.), provided the company widen the road so as to leave a space of not less than 9 ft. 6 in. between the outer rail and the kerb on both sides.

St. Pancras (London).—The chief electrical engineer (Mr. S. W. Baynes) has reported on the additional boiler plant required at King's road station.

Mr. Baynes states that the average yearly increased load during the past 10 years was 350 kw., and he estimates that the demand 15 years hence will have reached 9,871 kw. At present there are two generating stations, but for some years he has foreseen the desirability of collecting the generating plant under one roof, hence the introduction of three-phase plant and the opening up of sub-stations. He proposes that the generating plant at Regent's Park works should deal with the peak load only, and during the remaining nine months of the year it should be operated as a sub-station. It would be necessary to instal the following machinery: At Regent's Park works, two motor converters of 1,000 kw. each, with switchboards, &c., costing £5,900; three-phase trunk mains connecting King's-road with Regent's Park, £9,000. At King's-road, one spare turbo set, £9,400. Total, £24,300. The economies would be considerable, but they could only be brought about by extending the boiler plant at King's-road, and he submitted two schemes. He estimated the capital outlay on the first scheme as buildings, £18,200; boilers and superheater, coal conveyer and ash-handling plant, pipework, pumps, &c., £29,370; extra lengths of pipework, £932; extra length of coal transporter, £2,500; total, £51,002. The total annual expenditure under this scheme would be £4,744. The second scheme would involve a capital outlay of £84,549. The annual expenditure under this scheme would be £6,223. He estimated that the costs would be reduced from 1·02d. per unit sold to 0·69d. for 9,000,000 units, or a saving of £12,375 in one year. Altogether Mr. Baynes anticipates an immediate return of 11 per cent. on the capital invested after paying sinking fund charges at the higher rates now imposed by London County Council. But much as the boiler plant was needed, Mr. Baynes would not recommend a brick to be laid until a working arrangement is made with the Midland Railway Co., so that there would be direct means of running coal into the Council's works.

A special committee is to consider Mr. Baynes' report.

Salford.—Portions of the tramway track are to be relaid during the ensuing 12 months, at a cost of £13,000.

Sevenoaks.—The Council have called in Mr. W. M. Mordey to report upon the question of electricity supply in the district.

Sheffield.—Owing to the greatly increased demand for electrical energy, especially for power and heating, it has been found necessary to put in additional plant at Neepsend generating station, and an inquiry will be held next week into the Council's application for permission to borrow £78,000 for the purchase of the plant.

It appears that quite a new source of demand has developed in the form of energy for electric smelting furnaces in the East End works, and there are indications pointing to very considerable extensions in this direction. Already two furnaces have been connected to the supply mains, and others are awaiting connection.

Smethwick.—The Council have decided to oppose the Bill for the confirmation of the Smethwick Electric Lighting Provisional Order, which proposes to transfer the 1898 order from the Birmingham & Midland Tramways (Ltd.) to the Shropshire, Worcestershire & Staffordshire Electric Power Co.

Spain.—The Public Works Department have granted to the Compania General de Tranvias de Barcelona a concession for constructing and working an electric tramway from Sans to Coll. Blanch, Barcelona.

The Ministry of Public Instruction have decided to distribute 200,000 pesetas (about £7,400) for the purchase of experimental scientific appliances for the colleges in Barcelona, Granada, Oviedo, Salamanca, Santiago de Campostella, Seville, Valencia, Valladolid and Saragossa.

Stretford.—Some time ago a dispute arose between the Council and Manchester Corporation which has running powers over the local tramway lines, as to whether, under the existing agreement, Manchester could call upon Stretford to supply an abnormal demand for current caused by football traffic. Stretford contended that they could not be called upon to do so, but the Board of Trade arbitrator (Mr. S. Buckmaster, K.C.) has now decided against them.

Sweden.—The Swedish Budget for 1911 provides that additional expenditure on canals, electric works and railways is to be met by loans amounting to £729,000.

The Army Pageant.—We are pleased to learn that the technical side of the Territorial Force is occupying a prominent position in the Army Pageant which will take place at Fulham Palace from June 20 to July 2. The Electrical Engineers (London Division) have, in fact, been entrusted with the important task of carrying out the whole of the lighting for the pageant. The men of this corps have offered their services gratuitously not only during performances, but for the preparation as well, and have undertaken to carry out the wiring work for lighting the grand stand and dressing rooms, as well as the pageant itself.

The grand stand will be lighted by means of high candle-power metal filament lamps, hanging from the roof, and in addition a row of flame arc lamps will be used for the double purpose of lighting the stand and the camp behind it. Arc lamps will also be used for lighting the entrances, both for the public and the performers. The dressing-rooms, pay boxes, ambulance stations, &c., will be illuminated by means of incandescent lamps, and last but not least, the pageant itself will be made visible to the audience at night by means of arc lamps placed on the roof of the grand stand. In all some 30 arc lamps and 250 incandescent lamps will be installed, and owing to the situation of the supply will necessitate using many miles of wire. In addition to the above duties, the Electrical Engineers have also undertaken the work of installing and maintaining the telephone service between the directing station used by the pageant

Digitized by Google

master and the various entrances to the arena and dressing rooms. This necessitates the use of a 12 way exchange board. The whole of the wiring work will be carried on insulators overhead. As the whole of the profits of the pageant are to be devoted to Army Charities, we wish it every success, and take this opportunity of expressing our appreciation of those members of the Corps of the Electrical Engineers, who have so generously offered their time in such a good interest.

The Rand.—We have received from the "Investor's Guardian," 21, Lime-street, London, E.C., a copy of a work entitled "Reduction of Working Costs on the Rand," being a reprint of series of articles contributed to our contemporary by their special commissioner (Mr. Howard) appointed to investigate the position of the mining industry on the Rand. Among the factors in the great reduction of working costs which has taken place are (1) the employment of heavier stamps, (2) the increased use of machine drills, and (3) the introduction of electric power. The work, which is published at 1s., consists of 38 pages of statistical and other information which should prove interesting reading to investors in the Rand mining securities. In regard to electric power Mr. Howard states that:—

The increased use of electricity in substitution of, or as an auxiliary to, the usual steam power has had a beneficial influence on working costs, but it is anticipated that the greatly extended use of electricity will still further lower working costs in the immediate future. To any one acquainted with the steadiness of machinery worked by electric power, and the ease with which any one of the component parts is thrown in and out of gear without interference with the rest of the machinery, it is apparent that the important steps which have been recently taken to secure an ample supply of electric power to the Rand cannot fail to exercise a far-reaching influence on the future of the industry. The superintending engineer of the Consolidated Goldfields has stated that in future it will probably be found economical to operate electrically all underground winders at the two Jupiter inclines, which will be of large capacity and designed to reach the limits of the property, a distance of 4,500 ft. on the incline. The charge for electricity will be reduced in October when an appreciable saving in running costs at the Simmer Deep and Jupiter plant is anticipated, and the electrification of the plants of the subsidiaries of the Rand mines and the Eckstein group will be completed towards the end of this year.

United States Telegraphs and Telephones.—On the 27th ult. the Senate adopted an amendment to the Railroad Bill introduced by Mr. Lafollette, placing the telegraph, telephone and cable companies, with the exception of the wireless telegraph companies, under the Inter-State Commerce Law.

Ventnor (I.W.).—At the last meeting of the Urban Council, on the motion of Mr. Smith, a resolution was unanimously adopted that it was expedient to consider the means of reaching the different levels of the town, with special reference to the construction of an electric tramway, and that any necessary action should be taken without delay.

Walthamstow.—An inquiry was held last week into the application of the Council for sanction to borrow £950 for additional plant at the electricity works, consisting of an additional booster set with the necessary connecting cables, switchboard and instruments, and an extension to the switchboard gallery.

The electrical engineer and accountant are in future to arrange the prices to be charged for the purchase of any installation which has been fitted up under the "free" wiring scheme, the price to be arranged by estimating the present value of the installation, or by adding 5 per cent. interest to original cost, and making an allowance for the amounts paid as rental since the installation was connected. Payment is to be spread over two years if desired, with interest at 5 per cent.

Watford.—An inquiry was held last week into the Council's application for sanction to borrow £7,500 for extensions of the electricity undertaking.

The clerk (Mr. H. Morten Turner) and the electrical engineer (Mr. F. W. Purse) gave evidence of the financial position of the undertaking and of the necessity for extensions of mains, &c. There was some opposition on behalf of the gas company and the ratepayers' association.

Wigan.—The Council has engaged Mr. C. W. Mallins, general manager of the Liverpool tramways, to report on the question of the working of the tramways.

Willesden.—Consent has been given to the Metropolitan Electric Tramways to lay additional cables through Church-road, Stonebridge.

A sub-committee has been appointed to make arrangements as to renting premises to hold electrical exhibitions from time to time. The Electricity committee recommend the Council to undertake the sale of domestic apparatus such as electric irons, kettles, &c.

Wireless Telegraphy.—Owing to satisfactory reports received from the owners of small craft as to the result of working wireless apparatus on these small vessels the Admiralty have decided to equip the torpedo gunboat "Sharpshooter," at Devonport, with wireless apparatus housed on the upper deck, the power generating machinery being placed below the water line.

Workhouse Lighting.—Congleton Guardians are considering the question of wiring their workhouse.

Barnet Guardians have engaged an electrical engineer to report upon the proposal to light the workhouse electrically.

Chorlton Guardians have decided to wire a portion of the workhouse premises.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Barrow-in-Furness.—The accounts of the electricity undertaking for the year ended March 31 show a total capital expenditure of £114,570, an increase of £1,323.

The total revenue was £13,266 (against £12,902), including £12,995 from the supply of electricity. Total costs were £5,882 (£6,286), gross profit £7,384 (£6,615). Interest on loans absorbed £3,197 (£3,242) and sinking fund £3,973 (£3,757), leaving a net profit of £249, against a deficit of £384 in 1908-9. The maximum load was 662 kw. (624 kw.), the load factor 13·95 per cent. (13·65). The equivalent of 83,419 30-watt lamps is connected, against 78,119; 1,130,092 units of current were sold (1,057,330). The average price per unit for private lighting was 4·224d. (4·217d.), for power 1·375d. (1·398d.) and traction 1·923d. (1·936d.). The works costs were 0·912d. per unit (1·045d.), and total costs 1·249d. per unit (1·426d.).

Belfast.—The report of the city electrical engineer (Mr. I. W. Bloxam) states that the net profit of the electricity undertaking for the year ended March 31 was £11,040, an increase of about 33 per cent. over 1909, due to the material increase in the total quantity of electricity sold and the substantial reduction in cost of generation.

The revenue from the sale of electricity for lighting and power was £42,722, increase of 15·4 per cent. The number of units sold for lighting alone was 2,238,019, increase 8·9 per cent., and for power 2,004,045, increase 26 per cent. The cost of production per unit has been reduced 8·5 per cent. The total number of units supplied for traction increased by 2½ per cent., but the revenue diminished by £1,522. The total equivalent of 30 watt lamps connected is 376,722 (increase 15·8 per cent.) including the equivalent of 5,835 H.P. in motors. The number of consumers is 2,305, increase 17 per cent. The maximum combined load last winter was 6,915 kw., viz., 4,000 kw. lighting and 2,915 kw. tramways.

Bexhill.—The total income of the electricity department for the year ended March 31 was £10,244, and after paying expenses the gross profit was £5,086.

After paying interest, sinking fund, &c., the net profit was £624, making with £726 brought forward a total of £1,350. As the L.G. Board inspector has suggested that capital expenditure in respect of meters and public lighting should be defrayed out of revenue, the Electric Light committee propose to transfer £654 to capital account, leaving £696 unappropriated.

Bolton.—The receipts of the electricity department from the sale of current for the year ended March 31 amounted to £62,730, and included £20,609 for private lighting, £22,173 for power and heating, and £19,948 for traction. The total income was £73,579.

Working expenses were £38,637, and included £20,792 for generation, £1,045 for distribution, £3,140 for rents, rates and taxes, and £1,773 for management and general expenses. The gross profit was £31,941 making, with £2,680 brought forward, £37,622. Interest absorbed £8,563, and depreciation £19,248 (6 per cent. on mains and transformers, 7 per cent. on machinery, 10 per cent. on meters, motors and instruments); £356 was written off mains account, £454 was spent on new meters, and £881 on new motors, £1,000 was written off Duncan-street sub-station, and £6,500 was devoted to relief of rates, leaving £619 to be carried forward. The total capital expended is £359,690. The works costs were 0·436d. per unit against 0·472d., and the total inclusive costs 1·125d. against 0·1199d. 14,257,257 units were generated; 1,627,135 were sold for private lighting, 6,013,928 for power, and 4,352,208 were supplied to the tramways department. The average price per unit was 1·18d., against 1·23d. There are 2,628 consumers, representing an equivalent of 434,561 8 c.p. lamps; the power consumers number 400 (increase of 25), and there are 915 (816) motors of an aggregate of 10,017¼ H.P. (9,219¼ H.P.) on circuit.

Brighton.—The accounts of the electricity supply department for the year ended March 31 were submitted to the Council yesterday (Thursday).

Capital expenditure is £800,753, an increase of £20,108 over the previous year. The total net revenue was £88,856, an increase of £5,575, and the total costs were £37,439, a decrease of £619, leaving a gross profit of £51,417, an increase of £6,175 over 1908-9. Interest required £19,243 and sinking fund contributions £25,922, so that the net profit is £6,252, against £565. Income from the sale of current for private lighting showed an increase of £1,489 and for power of £1,243. Total works costs were 0·70d. against 0·78d., and the total costs (including loan charges) 2·19d. against 2·47d. per unit, and 9,041,844 units of electrical energy were sold, against 8,037,711; 4,092,821 units were supplied for private lighting (against 4,241,747), 1,141,400 for power (842,198), 1,015,106 for public lighting (1,036,107), 1,938,305 for tramways (1,889,410), 41,407 to Aldrington (28,249) and 812,805 units were supplied on private contract. The equivalent of 363,124 8 c.p. lamps is connected, against

Digitized by Google

333,143; there are 5,020 consumers, against 4,773. The maximum load on the feeders was 4,727 kw., against 4,437 kw., and the load factor was 21·8, against 20·1 per cent.

In the report of the engineer and manager (Mr. John Christie) it is stated that there had been a slight falling off in the sales for private lighting, due to the extended use of metal filament lamps, but it is stated that the department has now almost reached the point when additional business would enable them to show steady annual progressive increases. In regard to the use of power, the chief point was the substantial increase due, chiefly to the fresh business obtained in operating the railway shops, charging electric 'buses and the more general use of motors for driving industrial machinery. 34 motors were let on hire during the year (equivalent to 175 H.P.), bringing the total number on hire to 189 (947 H.P.) These motors had displaced a large number of small isolated steam plants, and the consequent reduction of the smoke nuisance must have a beneficial effect on the town. The sales to public lamps showed a decrease of 21,001 units, due to the extended use of metal filament lamps. The tramway output had increased by 48,895 units, and the reduction in price from 1·5d. to 1·25d. had benefited that department to the extent of £1,210.

At Aldrington (to which bulk supply was given) there were 117 consumers (with the equivalent of 5,562 8 c.p. lamps) connected to the mains. The great increase in output, obtained without a corresponding proportionate advance in maximum load, had raised the load factor from 20·1 to 21·8 per cent., thus effecting a substantial reduction in works cost. On coal the saving was 0·05d. per unit. They had sold over 1,000,000 units more than in the previous year, while the total cost for fuel had been £637 less. The surplus (£6,251) has been transferred to reserve.

Coventry.—At Tuesday's Council meeting the chairman of the Electricity committee (Mr. M. K. Pridmore) moved the adoption of the accounts of the electricity undertaking for the year ended March 31.

The year's revenue was £36,920 (against £30,607), and the receipts from the sale of current for lighting and power were £34,968 (against £28,500). The total expenditure was £11,380, but included in this amount are two items of £264 for repairs to motors on hire, &c., and £237 for attendance to public lamps. The gross profit was £25,540, and after paying all capital charges, £1,000 was voted to relief of rates, £2,598 was placed to reserve, leaving a net balance of £10,238, of which the committee recommended that £2,500 be applied in aid of rates, that £7,188. 11s. 4d. be placed to reserve to meet the cost of obsolete and superseded plant, &c., that £280. 9s. 6d. be placed to reserve, that £204. 18s. 8d. be applied in paying a bonus to the employees of the department, the balance (ff64. 3s. 6d.) being carried forward. The total capital expended is £241,098, an increase of £3,226. The units sold amounted to 6,093,825, including 5,859,792 for private lighting and power, and 234,033 to the public lamps, of which there are 117 on 59 brackets and posts. The total maximum supply demanded was 3,754 kw.

Mr. PRIDMORE said that, after paying expense (with interest and sinking fund) there was a net profit of £10,238, the highest amount in the history of the undertaking, and it was proposed to hand over £2,500 to the general district fund, £7,188 to a fund for obsolete plant and purchase of meters, £280 to reserve fund, and £204 as a bonus to employés of the department, the balance being carried forward. He urged that the Corporation should be satisfied with a fair return on the capital employed in the undertaking, and submitted that 1 per cent. was a fair return. Anything over that should go in the reduction of the price of current. As a matter of fact that would before long be established by Parliament, which would prevent other towns from devoting large profits to relief of rates.

Mr. HEWITT said the undertaking had borrowed £10,000 from the rates when it was a losing concern, and he thought that the undertaking should at least pay off that loan.

Mr. BETTMANN held that it was the first duty of the committee to put the undertaking on a sound basis. If manufacturers got a benefit from cheap current it enabled them to compete better with the manufacturers of other towns, and thus benefited the city.

Ald. WEST, a past chairman of the committee, spoke optimistically of the prospects of the undertaking, and called attention to the fact that about 1,500,000 units had been sold for power during the past year, which proved that the trade of the city had been flourishing. That increase had been produced at a cost of £1,412 less than the cost of the output of the previous year, and with the increase of only 179 tons of coal. The engine room stores was a remarkable item, as the cost worked out at only 6½d. per horse-power per annum. There was only one other Corporation in the country that was producing electricity at a lower cost than Coventry, and in that case they had a wonderfully good power load and a good tramway load. He would not be surprised if next year there was a neck-and-neck race between Coventry and Stalybridge for the blue riband of the lowest electricity works cost.

The report and accounts were approved.

Devonport.—For the year ended March 31 the total revenue of the electricity department was £17,819, including £16, 270 from the sale of current.

The cost of generation was £6,624, of distribution £839, public lighting £148, rates and taxes £446, private works £1,016, management expenses were £1,199, and after paying insurances, &c., the surplus was £7,468, out of which capital charges were met, leaving a net profit of £1,011. The outstanding capital expenditure is £112,451. The units sold amounted to 1,651,614, against 1,722,482, the decrease being accounted for by a drop of 124,907 in the units sold for traction. There are 439 consumers, against 397; the equivalent number of 8 c.p. lamps connected is 35,357, against 32,482. Total works costs were 1·337d. per unit, against 1·327d.

Dundee.—The receipts of the electricity department for the year ended April 30 were £39,908, compared with £36,975 in 1909, while the expenditure was £21,479 (against £24,928), which included £11,510. 8s. 7d. for generation of energy, £2,975. 10s. 6d. for distribution, £5,128. 9s. 11d. for rents, rates and taxes, and £1,864.2s.5d. for administration expenses. Gross profit was £18,429. 8s. 11d., against £12,046. 19s. 7d. Interest required £7,577, against £5,951, sinking fund £6,676 (£5,786), while there was set aside as depreciation £2,750, and to claim account £1,250. The balance carried forward was £1,259. 17s. 9d., against £1,256. 6s. 10d. The units sold were 6,144,956.

Lancaster.—The accounts of the electricity and tramways departments for year ended March 31 have been issued.

The total income of the electricity department was £9,625, including £5,438 from sale of current for lighting, £1,029 from power, £786 from public lighting and £1,845 for current for traction. Expenses came to £6,297 and after paying interest (£1,719) and providing for repayment of debt (£1,626) there was a balance of £84 which has been placed to reserve. The total capital expenditure is £63,252. 873,325 units were generated, 383,026 units supplied to private consumers by meter and 36,083 by contract, 260,519 units supplied to the tramways department and 74,826 to the public lamps (41 arcs and 84 incandescents). The equivalent of 75,842 8.c.p. (against 64,029) is connected and the motors aggregate 440 H.P. The total cost per unit sold was 1·48d. and the average revenue was 2·79d.

The income of the tramways department was £5,231 (including £4,993 traffic revenue) and the expenses came to the same figure, but after providing for interest and sinking fund there was a deficit of £2,897, against £3,235 in 1909. The total capital expended is £43,330. 1,335,534 passengers were carried and 166,394 car-miles run, the average receipts per car-mile being 7·2d.

Sunderland.—For the year ended March 31 the total revenue of the tramways department was £58,546.

The total expenditure was £37,216, including £17,298 for traffic expenses, £5,648 general expenses, £3,706 repairs and maintenance, and £10,565 power expenses. Gross profit was £21,330, increased by bank interest to £21,576. Interest on loans absorbed £7,848, and income tax £568, leaving a balance of £13,160. 0s. 4d. The repayment of loans required £10,092, reserve and renewals £2,444. 13s. 3d., Wheat Sheaf offices instalment £400, and Sea-lane shelter £225. The net balance, after taking into account £517. 18s. 4d. dividends from investments was £3,588, of which £2,963 was placed to reserve and renewals fund and £625 to Wheat Sheaf offices account, &c. During the year 14,380,214 passengers were carried (a decrease of about 500,000) and 1,461,592 car miles run (against 1,474,990), but owing to a reduction in price the amount paid for current was £1,867 less.

The average working cost per car-mile (including power) was 6·11d., and excluding power 4·37d. The general manager (Mr. A. R. Dayson) reports that all the cars have now been fitted with meters, and, as a result, there has been a saving in current, the units per car-mile having dropped from 1·19 to 1·15. The decrease in traffic receipts (£1,869) is stated to be due to the continuation of bad trade in the town, to the troubles in the adjacent colliery districts, and to unfavourable weather for seaside traffic to Roker.

The revenue of the electricity supply department was £49,361, and after paying expenses the gross profit was £28,351. Interest absorbed £12,524 and sinking fund £15,518 and £421 was required for renewals and special expenditure, leaving a net deficit of £112. The number of units sold was 7,848,815 (against 6,584,825 in 1909); for power 3,961,302 units were sold, an increase of 1,501,314; to ordinary consumers 1,761,576, a decrease of 127,332; for street lighting 426,179, an increase of 16,189, and for traction 1,690,918, a decrease of 79,483.

The electrical engineer (Mr. A. S. Blackman) states in his report that the outstanding features of the year were a partial recovery from the depression in the shipbuilding and engineering trades, the commencement of supply to consumers at e.h.t., the reduction of the price charged for traction (1¾d. to 1½d. per unit), representing a drop in revenue of £1,321, the introduction of the new Home Office Regulations relating to the generation, transformation, distribution and use of electrical energy, which necessitate alterations to portions of the works and sub-stations; the rapid introduction of the metal filament lamp, the reduction in the sale of electricity for lighting purposes consequent thereon, and the continued drop in the costs of production.

West Bromwich.—The capital expended on the electricity undertaking at March 31 was £75,118, an increase of £1,509 during the past year.

The income from the sale of current was £12,663, a decrease of £409, owing to the reduced demand for traction, which amounted to £1,282. There was an increase of £791 in revenue from private consumers, and of £82 from public lighting. Gross profit amounted to £6,349 against £6,856. After paying interest (£1,730) and redemption of debt charges (£2,862) there was a net profit of £1,756. 3s. 6d., a decrease of £686. 3s. 5d., compared with the previous year.

The net capital expended on the tramways department is £134,786. The full amount of rent chargeable to the Tramways (Lessee) Co., viz., £8,606, has been received less £502 income tax. The net profit on the rental of the tramways for the year is £246.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Electric Lighting committee of HULL Corporation invite tenders for supply and laying of electric mains, &c., required in connection with the extension of the electric lighting mains during the period ending March 31, 1911. Forms of tender and specification from the City treasurer, Mr. T. G. Milner, and tenders, addressed to the chairman of the committee, must be delivered at the Town Hall, Hull, by noon June 20. See also an advertisement.

WEST BROMWICH Electricity committee invite tenders for the supply, delivery and laying of paper-insulated lead-covered feeder and pilot cables. Specifications, forms of tender, &c., from the borough electrical engineer and manager, Mr. W. A. Jackson, Electricity Works, West Bromwich. Tenders to the chairman of the Electricity committee, Town Hall, West Bromwich, by noon June 20. See also an advertisement.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

BARNES Urban District Council invite tenders for supply of 4,000 yds. of 0·25, 0·25, 1·25 sq. in. triple concentric cable, paper insulated, lead sheathed and jute served, suitable for a working pressure of 660 volts, manufactured in strict accordance with the British Engineering Standards committee's specifications. Tenders to the Clerk to the Council, High-street, Mortlake, by noon June 14.

ERITH Council want tenders by noon June 20 for supply of a Lancashire boiler, mechanical stokers, superheater and pipework; a 750 kw. three-phase turbo-alternator, with surface condenser, air and circulating pumps and pipework. Specification from the Electrical Engineer.

DEVONPORT Corporation want tenders by noon June 15 for 12 months' supply of d.c. meters, paper-insulated cables, rubber-covered wires and cut-outs, lubricating oils, &c. Forms of tender, &c., from Borough Electrical Engineer.

The LIVERPOOL Overhead Railway Co. require tenders by 10 a.m. June 7 for 12 months' supply of electrical fittings, insulating tapes, iron and steel, ironmongery, oil and grease, packings, &c. Forms of tender, &c., from 31, James-street, Liverpool.

EALING Corporation require tenders by noon July 4 for supply and erection of surface condensing plant, &c., at the electricity works. Specification, &c., from Town Hall, Ealing.

MANCHESTER Electricity committee want tenders by 10 a.m. June 7 for 12 months' supply of stores, including carbons, dynamos, brushes, iron and steel, asbestos and rubber goods, oils, &c. Forms of tender from the Town Hall.

MANCHESTER Tramways committee want tenders by 10 a.m. June 7 for special (permanent way) track work. Specification from 55, Piccadilly, Manchester.

WEST HAM Education committee require tenders by 6 p.m. June 20 for the electric lighting of three schools. Specifications, &c., from Mr. Wm. Jacques, 2, Fen-court, Fenchurch-street, London, E.C.

BRISTOL Sanitary and Improvement committee want tenders by 10 a.m. June 13 for supply and erection of electrical plant and fittings at the proposed refuse destructor, Eastville, Bristol. Specification, &c., from City Engineer.

Tenders are wanted by noon June 13 for the electric lighting of the new asylum buildings on the Purdysburn estate, BELFAST. Specifications from Messrs. Watt, Tulloch & Fitzimons, 77A, Victoria-street, Belfast.

SOUTH SHIELDS Corporation want tenders by 10 a.m. June 13 for 12 months' supply of stores to the tramway department. Specification, &c., from the Tramways Manager.

WALLASEY Council require tenders by noon June 14 for the supply and erection of a water cooling tower. Specifications from engineer and manager of electricity department, Liscard.

SWANSEA Corporation want tenders by noon June 23 for 12 months' supply of motors and starting switches. Specifications, &c., from the Borough Electrical Engineer.

BIRMINGHAM Tramways committee require tenders by first post June 20 for supply of 2,100 tons of grooved steel girder tram rails with fishplates, &c. Specification, &c., from General Manager.

Tenders are wanted by noon June 6 for the electric lighting of the Stewart Institution, Chapelizod, DUBLIN. Specification, &c., from Mr. T. Tomlinson, 16, Beresford-place, Dublin.

CHORLTON Guardians want tenders by June 7 for the electric lighting of two blocks at West Didsbury Workhouse. Specifications from Messrs. C. Clegg & Sons, 21, Spring-gardens, Manchester.

The Penrikyber Navigation Colliery Co., PENRHIWCEIBER, Glam., require tenders by June 8 for 12 months' stores, including electrical fittings, ironmongery, oils, &c. Forms of tender from Secretary.

PORTSMOUTH Corporation want tenders by 10 a.m. June 22 for one or two years' supply of coal to the electricity department.

WALSALL Corporation want tenders by noon June 7 for erection of a sub-station. Forms from Borough Electrical Engineer.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of 130 miles copper tinned wire and 25,000 insulators. Local representation is necessary. Specifications, &c., from 72, Victoria-street, London, S.W.

Tenders are invited for supply of 1,470 opalescent arc lamp globes to the city of MELBOURNE. Specification, form of tender, &c., from the agents of the City Council (Messrs. McIlwraith, McEacharn & Co. Propty., Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon June 8.

Tenders are also invited for supply of 941,000 arc lamp carbons to the city of MELBOURNE. Tender form, specification, &c., from the agents (Messrs. McIlwraith, McEacharn & Co. Propty., Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by Friday, June 17.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zinc for batteries. Local representation is necessary.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

The Netherlands Colonial Office, THE HAGUE, Holland, will receive tenders on June 7 for supply of 3,000 iron telegraph poles and 500 top tubes (contract La C. 15). Specifications from M. Nyhoff, 18, Nobelstraat, The Hague (price 1s. 8d.).

The ITALIAN State Railways Department want tenders for supply of 19,600 glass shades for electric lamps in railway carriages. Tenders to 16, Via Ludovisi, Rome, by June 14. Only firms on the list kept by the department are usually allowed to tender.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit

Digitized by Google

of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Marylebone (London) Council have accepted the following tenders for annual supplies :—

Rands & Co., ceiling roses, ordinary, 1s. 11d. per dozen; tumbler switches, linked and mounted, 10 and 20 amperes, 32s. per dozen and 5s. 4d. per pair. T. L. Scott & Co., tumbler switches, 5 and 10 amperes, 6s. and 11s. 6d. per dozen; d.p. distribution boards, 5 amperes, 1s. 9d. to 10s. 6d. each; china bridge fuses, 1s. 9d. per dozen; s.p. cutouts, 100 amperes, 22s. 6d. per dozen. Edison & Swan Co., wall plugs and sockets, 10 amperes, 14s. 6d. per dozen; switch plugs, 10 and 5 amperes, 34s. and 22s. per dozen; d.p. distribution boards, 10 amperes, 2s. 6d. to 15s. 6d. each; lamp holders, 2s. 9d. and 3s. per dozen; shades, 10 in. opal, 2s. 9d. per dozen; 10 in. green opal, 7s. 4d. per dozen; enamelled iron, 10 in., 2s. 9d. per dozen. Union Electric Co., 23 in. 10 mm. (metal core) arc lamp carbons (flame) per 250 ft., 28s.; 23 in. 9 mm. do., 19s. 3d.

West Bromwich Corporation received the following tenders for 1,000 kw. direct-current turbo-generator :—

C. A. Parsons & Co. (*accepted*); Richardsons, Westgarth & Co., three tenders (Brown-Boveri, Siemens and Westinghouse generators); James Howden & Co., two (Brown-Boveri and Siemens generators); Willans & Robinson, four (Brown, Boveri, G.E.C., E.C.C. and Siemens generators); Brush Electrical Engineering Co. and British Westinghouse Co.

For a surface condenser the Corporation received tenders from the following :—

C. A. Parsons & Co. (*accepted*), Richardsons, Westgarth & Co., Willans & Robinson, Mirrlees-Watson Co., Brush Co., W. H. Allen, Son & Co., British Westinghouse Co., Midland Engineering Co., Worthington Pump Co., John Thompson and Isaac Storey & Son.

Salford Education committee have accepted the tender of the British Westinghouse Co. for wiring the Wellington-street schools at £146.

Salford Council have accepted the following tenders :—

W. Lucy & Co., house service cut-outs; Liverpool Electric Cable Co., rubber covered cable; W. T. Glover & Co., paper insulated cable; C. Macintosh & Co., twin workshop flexible; British Westinghouse Co., wiring Wellington-street school (£146. 8s. 6d.); Thames Ironworks, &c., Co., combined evaporator and distiller for new battery "make up" water (£59).

The following tenders have been accepted by the Australian Postmaster-General's Department :—

British Insulated & Helsby Cables, multiple magneto switchboard for Canterbury telephone exchange, £2,239. 13s. 11d.; Sydney Electrical Engineering Co., electric lighting of Newcastle (N.S.W.) Post Office.

Kingston Council has accepted the following tenders :—

W. T. Henley's Telegraph Works Co., for ½ mile of 5 ampere cable at £44. 10s., and ½ mile of 35 ampere cable at £87. 10s.; and Siemens Bros. & Co., for ½ mile of 12 ampere cable at £58, and ½ mile of 22 ampere cable at £71.

Grimsby Council have accepted the following tenders :—

J. H. Tucker & Co., fuse boxes, £37. 10s.; Phœnix Dynamo Mfg. Co., three-wire balancer, £38; Chamberlain & Hookham and Ferranti Limited, meters; W. Lucy & Co., 300 c.i. lamp-posts, £326. 5s., and incandescent lamp fittings, £248. 3s. 9d.

Walthamstow Council have provisionally accepted the following tenders :—

General Electric Co. feeder booster set, £468; B. Thomas, switchboard, £242. 10s.; General Iron Foundry Co., constructional ironwork for switchboard gallery extension, £87.

Eccles Council have accepted the following tenders :—

British Insulated & Helsby Cables, h.t. concentric paper-insulated cable (£459. 11s. 3d.), and N. Brookes & Sons, construction of foundations for new steam dynamo, &c.

The order for replating the lighting battery at Derby, consisting of 240 cells, has been placed with the Chloride Electrical Storage Co. at £100, and six annual payments of £93, and maintenance for 12 years at £70 per annum.

The tender of G. F. Endersby has been accepted for supply of a reversible booster, storage battery and switchboard panels to Rochdale Corporation.

Dartford Council have placed orders with Chamberlain & Hookham and Ferranti Limited for 12 months' supply of meters, and with E. E. Beaven for general stores, &c.

The Metropolitan Asylums Board have accepted the tender of W. J. Fryer & Co. (at £51. 17s. 6d.) for wiring the assistant medical officer's quarters, North-Eastern Hospital.

Bishop Auckland Guardians have accepted the tender of E. Thompson & Co. for wiring their new infirmary at £78.

Stretford Council have accepted the tender of the General Electric Co. for a 500 kw. steam dynamo at £2,764 and spare armature at £325.

Derby Council have also accepted the following tenders :—

Electric Construction Co., switchboard extension, £303, and motor generator, £683; W. Rickard (Ltd.), bitumen cable, £1,721. 10s.

Middlesex County Council has accepted the tender of Dick, Kerr & Co. (at £429) for laying a double instead of an interlacing line in High-road, Willesden, widening the road, &c.

Sunderland Corporation have accepted the tender of the United States Metallic Packing Co. for a rail grinding machine.

Morecambe Council have accepted the tender of Edmondson Bros. for erecting a cooling tower at the electricity works.

Water Purifying Plant.—Among orders recently received for Paterson water purifiers are the following :—

H.M. Dockyard, Pembroke, repeat order for generating station; Hull Corporation, repeat order for tramway power station; G.P.O. generating station, Blackfriars (through Messrs. Aiton & Co.); Messrs. J. G. White & Co., repeat orders for Lacroze electric tramways (Buenos Aires) and Para Electric Light & Tramways Co.; and Midland Electric Corporation for Power Distribution, for Ocker Hill generating station.

Plant for Sale.—An 80 kw. Willans steam dynamo is advertised for sale.

Some second-hand electric motors are advertised for sale in another column.

Premises to Let.—Premises suitable for manufacturers are advertised to be let in the east of London.

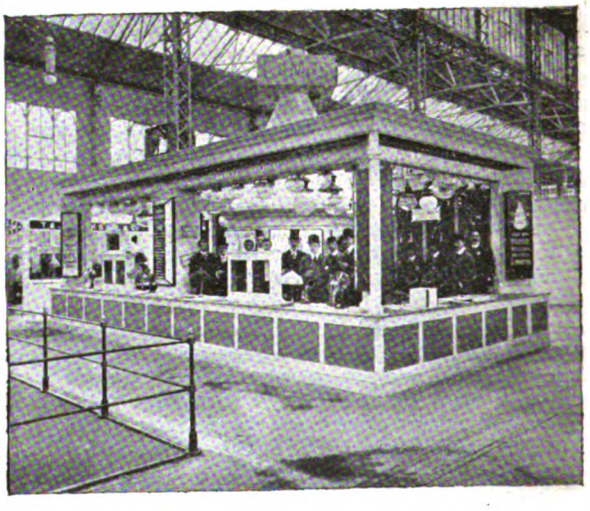
Patents Development.—The proprietors of the following patent desire to enter into arrangements by way of licence and otherwise for exploiting and developing the same in this country :—

No. 12,210/1901, relating to "Electrostatic Separators." Applications to Messrs. Cruikshank & Fairweather, 65 and 66, Chancery-lane, London, W.C.

"The Journal."—Part 201 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. Particulars of contents are given in an advertisement.

"Indespenso Connectors."—A correspondent wishes to know the address of the manufacturers of "Indespenso porcelain connectors for electrical work." Will any reader please supply the information?

Japan-British Exhibition.—The accompanying photograph shows the General Electric Co.'s stand at the Japan-British Exhibition, the various features of which were described in last week's issue. It will be remembered that a great feature made is the utility of Osram



lamps for all purposes, while fans and other small electrical apparatus are shown on the market. The photograph clearly shows the various features of the stand, from the illuminated sign on the top to the artistic counter at the foot. The only thing left out are the interested onlookers, who seem to foregather round the General Electric Co.'s stand from every quarter of the Machinery Hall at all times of the day.

"Rugby" Metal Filament Lamps.—The Rugby Lamp Co., which has a modern factory at Rugby for the production of incandescent lamps, makes a speciality of metal filament and carbon filament lamps for all purposes.

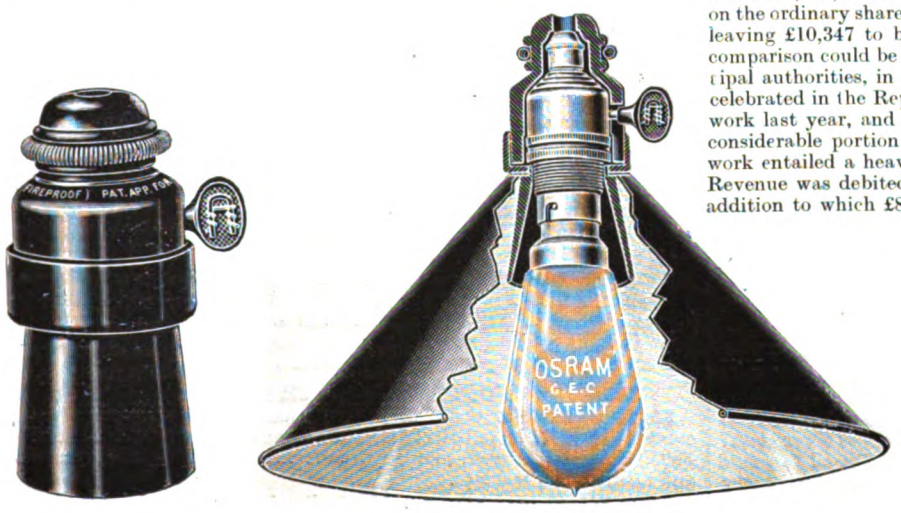
Although the "Rugby" lamps have only been on the market for about two years, important contracts have been obtained from leading railways, tramways and steamship lines at home and abroad. Owing to the success of these lamps an extension of the factory has already become necessary. The selling agents for the "Rugby" lamps are Messrs. J. L. Cateaux & Co., 10, Bush-lane, London, E.C.; Taylor & Hutchinson, 23, Drury Buildings, Liverpool; and J. W. Maw, 40, Angel-street, Sheffield.

Digitized by Google

Tantalum Lamps.—Messrs. Siemens Bros. Dynamo Works, Tyssen-street, Dalston, N. E., have decided to reduce the price of tantalum lamps as from June 1, and copies of the revised list of prices are now available. The discounts, terms for contracts, &c., will remain exactly as hitherto, whilst the quality of the lamps will be, if anything, improved. The list will be supplied promptly in quantities to any contractor or electrical dealer for distribution amongst their clients.

A revised prices of tantalum lamps, showing full trade discounts, terms, &c., is issued by Messrs. Drake & Gorham, 66, Victoria-street, Westminster, London, S.W., and can be obtained on receipt of trade card.

Coates Patent Insulating Shield.—In connection with the Home Office regulations issued February, 1910 (Regs. 13 and 21), the General Electric Co. are placing on the market a new pattern of insulating shield, which is shown in the accompanying illustrations. When in position this shield entirely encloses all metal parts of the lamp-holder, and, at the same time, insulates the shade from the holder. The material employed is of a special nature, and after making tests, Mr. S. G. Castle Russell, M.I.E.E., states that these show that the material covering the holder is entirely satisfactory from a fire risk point of view. A novel and important feature is that the shield can be fitted without unwiring the holder, this operation being



simple and taking only a few seconds of time. The General Electric Co. will have ready in a few days a new price list illustrating and describing these shades.

CATALOGUES, &c.

"Freezor" Fans.—The General Electric Co. are sending out a small folder giving particulars of the special line of "Freezor" fans which they have just placed on the market. The company are willing to supply these folders in quantities to contractors and central station engineers and to print the name free of charge.

Oerlikon Fans and Ventilators.—We have received from the Maschinenfabrik Oerlikon (whose London office is Norfolk-street, Strand, W.C.) a publication dealing with this subject. Special points of the Oerlikon fans are that all parts are interchangeable, running is noiseless and current consumption is exceptionally low.

Ediswan Pendants and Electroliers.—The Edison & Swan United Electric Light Co. send us three fully illustrated leaflets dealing with this subject, and giving sufficient details as to price and design.

Electrical Fixtures.—Messrs. Falk, Stadelmann & Co.'s new catalogues deal fully with electrical fixtures supplied by them.

BANKRUPTCIES, LIQUIDATIONS, &c.

A dividend is to be paid to creditors of Robt. H. Walker, electrical engineer, &c., Elgin-road, and 16, Widemarsh-street, Hereford, and claims are to be sent by June 11 to Mr. M. J. G. Scobie, O.R.'s office, Hereford.

Wm. Hy. Trentham, consulting engineer, 39, Victoria-street, London, S.W., has been adjudicated bankrupt.

Meetings will be held at the office of Mr. A. R. Lancaster, Queen's College, Birmingham, on June 28, to receive accounts of the winding up of the Automobile Electric Lighting Synd. (Ltd.) and the Polkey Automobile Electric Lighting Synd. (Ltd.).

Mr. C. S. Beale, 72, Bishopsgate-street Within, London, E.C., has been appointed liquidator of the Typewriting Telegraph Corpn. (Ltd.)

The liquidator (Mr. H. de V. Brougham, 39, Carey-street, London, W.C.) of the British Power, Traction & Lighting Co. (Ltd.) has been released.

A first and final dividend of 10d. is payable at the O.R.'s, Station-road, Gloucester, to creditors of Walter S. Jenkinson, electrical engineer, Rodborough, near Stroud.

A dividend is to be declared under a deed of assignment executed by Wm. Hy. Alvey (trading as Alvey & Bower), electrical engineer, &c., Chesterfield. Claims by June 24 to Mr. S. E. Short, 17, Glumangate, Chesterfield.

COMPANIES' MEETINGS AND REPORTS.

ANGLO-ARGENTINE TRAMWAYS CO. (LTD.)—At the meeting on Wednesday the chairman (Mr. J. B. Concanon) said that during 1909 they had carried 223,823,792 passengers. The total receipts were £1,938,887 and the expenditure (including £50,000 carried to depreciation renewals fund) totalled £1,207,222, leaving a net profit of £731,665. After providing for fixed charges, dividends on both classes of preference shares, nine months' rent of the Metropolitan tramways, &c., the surplus was £140,972, from which had to be deducted the interim dividend paid on the ordinary shares and the further dividend which they recommended, leaving £10,347 to be carried forward. Owing to the fusion no useful comparison could be made with the previous year's working. The municipal authorities, in anticipation of the centenary which was now being celebrated in the Republic, undertook a large amount of street re-paving work last year, and they took advantage of the opportunity to relay a considerable portion of their lines on a deeper concrete base, and that work entailed a heavy expenditure under the head of permanent work. Revenue was debited under the head of maintenance with £207,486, in addition to which £83,648 was expended upon renewals. The profit in Buenos Ayres from Jan. 1 to April 30 last was £316,433, and they anticipated that the profits for the remainder of the year would be at least in the same proportion, or, say, £950,000 for the whole year. Deducting London expenses, and taking credit for sundry receipts, there would remain a surplus of £940,000. The City company annuity, interest and sinking fund on debentures, dividends and sinking fund on first and second preferences, &c., require £665,000, leaving £275,000 available for renewal funds, appropriation and dividends on ordinary shares. Some of them might feel surprised that, in view of the great success of their present system of surface lines, they should embark upon an enterprise which was somewhat novel and involved such a large expenditure of new capital. The whole of the £8,000,000 new debenture and share capital would not be required for the construction and equipment of the subways. The total cost of the subways and their equipment would not exceed £5,000,000, and the execution of the work would be spread over a considerable number of years. The last section could not be constructed before eight years. The directors came to the conclusion that it was absolutely necessary to provide for further development of the traffic in the suburbs by enabling the public to get quick and efficient access to the business centres, otherwise than by their surface lines, which indeed was becoming a physical impossibility. The municipal authorities met the company in a most enlightened spirit, the result being that the company had obtained the subway concession. From his personal knowledge of the city of Buenos Ayres he had no hesitation in saying that he considered the conditions for working combination services of surface and subway lines in Buenos Ayres were ideal. They anticipated that the working expenses of the subways would be only about 45 per cent. against about 60 per cent. as at present on the surface lines.

The report and accounts were adopted, and resolutions increasing the capital by £8,000,000 were agreed to.

BRUSH ELECTRICAL ENGINEERING CO. (LTD.)—The accounts for 1909 show a gross profit of £22,528. 16s. 9d. After debiting general charges and maintenance, the net profit is £1,811. 12s. 11d. Debenture and other interest charges and bad and doubtful debts written off have absorbed £23,042. 6s. 4d., leaving a loss of £21,230. 13s. 5d. The conditions at the beginning of 1909 were unfavourable, and although the orders secured during the year showed a considerable improvement over the previous 12 months, it was not possible to make up for the shortage of invoicing during the earlier months. The directors' report states that the current year will benefit by the larger volume of unfinished work in hand at Dec. 31 last. Compared with 1908 a reduction of over £16,000 was effected in the general charges for the past year. The directors regret that the depression which has so long affected the engineering industries of the country still continues, and although there has been some improvement of late, the demand for steam and electrical machinery, as well as for rolling stock, is still far below the normal, and the great competition renders the prices obtainable for the most part unsatisfactory. There has, however, been an increased output from the works

Digitized by Google

during the first five months of 1910, and it is hoped that this increase, coupled with the reduced working expenses, will lead to improved results. The directors report with satisfaction that the turbo generators manufactured by the company have gained a high reputation, and good orders are being received for plant of this description to work with live, mixed pressure, and exhaust steam. The company is interested in a variety of promising electrical and engineering developments.

DELAGOA BAY DEVELOPMENT CORPN. (LTD.)—At the meeting last week Mr. H. K. Heyland said the directors had been considering the question of acquiring the property of the Lourenco Marques Electric Light Co., which had declared a dividend of 2½ per cent. for 2 years. Their consulting engineers (Messrs. Mordey & Dawbarn) had reported that a considerable saving would result from the joint working of the two companies. For some time past the Board has felt that two electric power stations in Lourenco Marques was somewhat anomalous, and to bring both under one management must obviously result in a considerable saving in working costs. This economy would amount to £1,560 or £2,000 per annum. There was also a third power station in Lourenco Marques, owned by the Portuguese Government for working their railway shops and some cranes in the wharf. At present the Delagoa Bay Corpn. supplied a certain amount of power to the wharf, and they hoped eventually to be able to come to some agreement with the Government for the supply of all the power they required for their wharf and railway.

IMPERIAL TRAMWAYS CO. (LTD.)—At the meeting on Tuesday Sir. Geo. White said that the Middlesbrough, Stockton and Thornaby electric undertaking had suffered from want of full employment in the engineering and shipbuilding trades, and also from weather conditions. No dividend had been received on their principal investment (44,446 5 per cent. cumulative preference shares of £10 each) in the London United Tramways, and the arrears of dividend amounted to £27,778. For the 16 years during which the directors had had the management of the Imperial Tramways not only had the preference dividend been punctually paid, but the ordinary share dividends had averaged 10 per cent. in cash. From what the chairman of the London United Co. said in his recent speech, it was evident that whatever profit over and above their debenture interest was earned during the present year would be kept for renewals and reserve, and the Imperial Co. was therefore unlikely to be in receipt of sufficient income to pay the preference and ordinary dividend during 1910. The London United undertaking was undoubtedly a valuable property, and even in its present unfavourable position, with competition raging all round, it carried between 50,000,000 and 60,000,000 passengers a year, had a gross income of well above £300,000 and a net revenue of between £90,000 and £100,000 a year.

MIRRLEES, BICKERTON & DAY (LTD.)—We learn that at the recent meeting (at the works, Hazel-grove) the chairman (Mr. A. F. Baird) moved the adoption of the report, which showed profits available for disposal amounting to £5,577. 11s. 1d. The directors recommended that £4,000 be applied in paying a dividend at the rate of 5 per cent., £1,000 be placed to reserve, and the balance (£577. 11s. 1d.) carried forward. Mr. Baird pointed out that the works and equipment were now completed and in good working order, and that experience had proved they could produce, at a profit, Diesel engines which are exceedingly satisfactory. During the year important agencies have been established in foreign countries, and the company had supplied engines to China, Japan, India, Java, Bulgaria, the West Indies and other parts of the world. The discoveries of oil and starting up of new oil companies in many parts of the world would doubtless have a beneficial effect on their business. Under the auspices of the Argentine Government the company had on exhibit one of their engines at the exhibition in Buenos Ayres.

MONTEREY RAILWAY, LIGHT & POWER CO.—At the recent meeting it was reported that the Company now operates about 25½ miles of line, which is fully equipped with modern electrical plant and rolling stock. The company purchased all the capital stock of the Monterey Light and Power Co. in 1908, prior to which the directors had been negotiating with the Government for a concession to enable the company to do an electricity supply and gas business in and about the City of Monterey. During 1909 the negotiations resulted in the company getting a new concession for 99 years, from March 10, 1905, for an electric lighting, power and gas service in the city on satisfactory terms. The intention is to amalgamate the power plants of the Railway Co. and the Light and Power Co.

POTTERIES ELECTRIC TRACTION CO. (LTD.)—Mr. G. F. M. Cornwallis-West stated at the meeting last week that the company's increased balance (£4,830) was entirely due to lessened working expenses. Power, running and parcels expenses had been reduced by £1,023, repairs and maintenance by £2,876 and administration and general expenses by £1,236. The traffic receipts showed a decrease of £400. The parcels business formed quite a useful profit-earning adjunct, and year by year showed healthy growth. They had tried the "fair fare" system, but it had not yet been in operation for a sufficient length of time to test its increased earning capabilities.

SHANGHAI ELECTRIC CONSTRUCTION CO. (LTD.)—The chairman (Sir Alfred Dent, K.C.M.G.) stated at the meeting last week that there had been an increase both in gross and net receipts, but those had been more than absorbed in expenses, and the result was a loss of £949. The loss in exchanges alone accounted for £13,341, besides which they had paid to the council £2,774 as royalty and a substantial sum for the maintenance of the public roads.

TYPEWRITING TELEGRAPH CORPN. (LTD.).—At the meeting on Friday last the chairman (Mr. A. J. Parker) moved an extraordinary resolution that, by reason of its liabilities, the company should be wound up. He said they had a machine which was an exceedingly good one, but the Government had unfortunately refused to take it up. They had now no customers to go to, either in England or abroad, and the bulk of their foreign patents had run out. Although they had tried every source, they were unable to sell their machines. The resolution was carried.

WINNIPEG ELECTRIC RAILWAY CO. (LTD.)—The net earnings for 1909, after providing for operating expenses, Municipal Council's proportion of earnings, &c., amounted to $863,405, out of which the directors declared four quarterly dividends ($600,000), leaving $263,405, which, with amount brought forward, made $861,430. The company's hydraulic works at Pinawa Channel were very satisfactory up to Nov. 23, when one of the penstocks burst, causing the closing down of the whole plant for six days. While the hydraulic plant was closed down a partial service was maintained by the steam plant. During the year nearly 5 miles of track was laid and 30 double-truck closed cars were constructed and put into service. In connection with the electric lighting and power-distribution system 749 new poles were erected and 120,141 lb. of wire, with 129 transformers, put up, in extension of the company's lighting and power-distribution system.

NEW COMPANIES, STATUTORY RETURNS MORTGAGES AND CHARGES.

NEW COMPANY.

TRANSIT CO. (LTD.) (109,799.)—Reg. May 24, capital £2,000 in £1 shares, to construct or acquire any tramways or light railways in United Kingdom, to carry passengers and goods, &c. Private company. Reg. office, Atherton, Lancs.

STATUTORY RETURNS.

ST. JAMES' & PALL MALL ELECTRIC LIGHT CO. (LTD.)—Return to March 1 capital is £300,000 in 40,000 ordinary and 20,000 preference shares of £5 each. All shares taken up. £298,250 paid on 39,650 ordinary and 20,000 preference. £1,750 considered as paid on 350 ordinary. Mortgages and charges, £150,000 3½ per cent. debenture stock and £205,472 4 per cent. guaranteed stock of Central Electric Supply Co.

SIMPLEX CONDUITS (LTD.)—Return to March 24 gives capital as £100,000 in 10,000 preference shares of £5 each and 50,000 ordinary shares of £1 each. 10,000 preference and 40,000 ordinary shares taken up. £50,000 paid on the preference. £40,000 considered as paid on the ordinary. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

BALCHIN, SCHULZ & CO. (LTD.)—Particulars of £1,000 debentures, created May 13, have been filed, the amount of present issue being £500. Property charged, company's undertaking and property, present and future. No trustees.

HOWE ELECTRICAL ENG. CO. (LTD.)—Particulars of £500 debentures, created by resolutions of May 13 and 19, have been filed, whole amount being now issued. Property charged, company's undertaking and property, present and future, including uncalled capital. No trustees.

RECEIVERSHIP.

B. JOHNSON & SON (LTD.)—Notice of the appointment of T. Coombs, King-street, Leeds, as receiver and manager, on May 21, has been filed.

CITY NOTES.

MEMORANDA (June 2).—**Bank rate 3½ per cent.** (since June 2, 1910). **Price of silver,** 24⅝d. per oz. Consols 82⅝—82⅞ for money; 82⅝—82⅞ for account. Consols Pay Day, July 1; Stock and Shares Continuation Days, June 8 and 27; Ticket Days, June 9 and 28; Pay Days, June 10 and 29; Mining Shares Carry Over Day, June 7.

PRICES OF METALS (London).—*Copper*, cash, 56⅞; three months, 57⅜. *Lead*, English, 12¾—13¼; foreign, 12⅜—12⅝. *Spelter*, 22⅜—22½. *Tin*, English, 148—150; foreign cash, 149; three months, 150¾. *Iron*, Cleveland, cash, 49/6½, three months, 50/6.

MACKAY COMPANIES.—The regular quarterly dividend of 1 per cent. on the preferred shares and the regular quarterly dividend of 1¼ per cent. on the common shares in the Mackay Companies will be paid on July 1. The transfer books will not be closed.

ROBERTSON ELECTRIC LAMPS (LIMITED & REDUCED).—A petition has been presented to the High Court for the confirmation of a resolution reducing the capital of this company from £100,000 to £35,000.

SIEMENS BROS. & CO. (LTD.)—The directors announce a dividend of 4 per cent. (4s. per share) for the past year, allocating £23,600 for repairs to c.s. "Faraday," and carrying forward £3,689 to the pension fund.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted a quotation to a further issue of £23,500 5 per cent. mortgages of the *North Metropolitan Electric Power Supply Co.* The committee have been asked to grant quotations to £1,000,000 4½ per cent. first and general mortgage 30-year bonds (issued in Amsterdam) of the *New York Telephone Co.* and a further issue of £28,213 4½ per cent. first mortgage debenture stock of the *Rangoon Electric Tramways & Supply Co. (Ltd.)*

NOTES.

Free Trade or Protection for the Electrical Industry.

THE conclusion of the debate inaugurated by the National Electrical Manufacturers' Association was distinctly more interesting than the opening thereof, and more than ever demonstrated the fact that there is much to be said on both sides. Unfortunately, it demonstrated also the impossibility of proving either case satisfactorily. There is too much that is uncertain and too much about which an argument can be woven in either direction. It is this that has given rise to much of the complexity, and probably holds people back on both sides. Considering that the effect of Protection cannot be absolutely proved, there is a very natural tendency on the part of many people to feel that its introduction might not produce the results hoped for by its advocates; a feeling that at least we know where we are with Free Trade, and that "bad one knows is better than bad one doesn't know."

IN regard to the question of efficiency, so strongly urged by Mr. KINGSBURY, the position of the boot industry is strong evidence of the undesirability of protecting an industry that is in a bad state. We believe that the milling industry is another example of the same kind, in which the highest possible efficiency has been brought about by necessity, and the result in the end has been satisfactory. Another point is the general good of the country. In our recent comments on this subject we seem to have misunderstood Mr. KINGSBURY on this item. It is not a question of the electrical industry on the one side and the general good on the other, but whether, if the general good suffers, the electrical industry will not suffer still more. In discussions of this kind much depends upon definition. People speak in a general way about raw materials "which would not be increased in cost," but they do not define what they mean by raw material. Thus, wire is raw material unless the man who buys it is equally prepared to draw copper. Similarly, prosperity is a term which often requires definition. If the electrical industry could be protected by itself, then we do not suppose there is any question that it would reap a benefit, but the case is not so clear when every other industry is to be protected also, and when those that shout the loudest get the most. There is also little doubt that we cannot hope to retain the same position as we had in the old days before other countries had developed on the manufacturing side.

ON the other hand, it is very difficult for many people to understand why this should be the only country in the world for which Free Trade is good. It would be an ideal thing from the British point of view if there were Free Trade universally. But why have other countries not adopted it when presumably their political economists are as good as ours? Also, why should Germany under Protection export nine millions compared with this country's three and a half millions under Free Trade? Another ideal is to buy in the cheapest market and sell in the dearest, but it is difficult for us to sell in the dearest when we are kept out of it by tariffs. Everyone seems to be agreed that there is too much competition, and the only way of regulating this, as regards the foreigner, is by tariffs. Again, there is the large question of wages. If other countries give lower wages than here, they have a double advantage, and it would seem that wages in this country must fall if we are to compete successfully. Then, again, there is the question of unemployment, which one speaker stated to be much more serious here than in Germany. In conclusion, we congratulate the National Electrical Manufacturers' Association on this interesting discussion. It may not have convinced many people on either side, but it is an advantage for the arguments on both sides to be put forward; and if we might make a suggestion for a future occasion it would be that a similar discussion should be arranged on the question of internal competition, as distinct from competition by foreign trade. This may be described as the other side of the picture, and possibly it is not the least important.

Tramway Comparisons.

AT first sight the car-mile seems to offer a desirable basis for comparing the results achieved on different tramway systems. Like the kilowatt-hour in electricity supply it certainly has the merit of simplicity; but whereas the B.O.T. unit of electrical energy is universally adopted for calculating and comparing the cost of electricity generation and supply, tramway managers are far from satisfied—and rightly so—with the car-mile basis for comparative statements of revenue and working expenses. The kilowatt-hour is the product of two well-defined quantities; on the other hand, the car-mile involves a very indefinite quantity—viz., the car, to say nothing of its occupants. The use of the ton-mile as a unit has been suggested as a way out of this difficulty, but this unit would mainly be useful in ascertaining the relative power consumption in different cases. Again, the seat-mile has been suggested, and a month or two ago, in one of our American contemporaries, a "traffic unit" equal to 1,000 seat-miles was put forward. This unit is for many purposes undoubtedly an improvement on the car-mile. In regard to other units, it will be remembered that Mr. J. H. RIDER last year, in considering the question of energy consumption on tramways, introduced a "figure of merit," obtained by multiplying the units per car-mile by 100, and dividing the product by the average weight of the car in tons and the average speed in miles per hour.

AT the Dublin Congress of the Tramways and Light Railways Association this week, Mr. J. R. SALTER proposed a figure of merit obtained by dividing the number of car-miles per route-mile per annum by 10,000, and multiplying the quotient by the receipts per car-mile. The resultant figure, he claims, enables tramway systems to be compared better from a commercial point of view. The above expression may be written :—

$$\frac{\text{Number of car-miles per annum}}{\text{Length of route in miles} \times 10{,}000} \times \frac{\text{total receipts per annum}}{\text{number of car-miles per annum}},$$

and simplifies to 1/10,000th of the annual revenue per mile of route. It will be seen, therefore, that the figure mainly indicates the density of the traffic served by the tramway in question. Mr. SALTER particularly emphasised the importance of the first part of the above expression, which he terms the "density factor," and which is equal to 1/10,000th of the number of car-miles per route-mile per annum. This might certainly, with advantage, be included in tramway accounts.

IT is customary to express the working expenses per car-mile as a percentage of the receipts. This percentage in municipal tramway undertakings last year varied from 48 per cent. at Portsmouth to 111 per cent. at Lancaster. As Mr. SALTER points out, however, this figure is of little importance as an indication of the financial success of a tramway undertaking, since it can be reduced by curtailing the service, to the detriment of the net profit. In fact, it is evident that the more frequent the service the greater will be the percentage of the working expenses to the receipts to obtain a given result. The author in this connection draws attention to the frequent mistake of endeavouring to obtain high receipts per car-mile. A glance through the tabulated receipts of tramway undertakings will show that in a number of cases average receipts of from 10d. to over 13d. per car-mile are recorded; and as several of these undertakings show only a small profit on the year's operation, it would be interesting to see if improved results could be obtained with a more frequent service.

I.E.E. Council Elections.

WE desire to call attention to a letter appearing in our Correspondence columns from Mr. E. W. COWAN in regard to the method of selecting candidates for the Council of the Institution of Electrical Engineers. Mr. COWAN urges that the present Articles of Association evidently do not meet the case, and that they should be modified on the lines adopted by the American Institute of Electrical Engineers. We think there is a great deal to be said in favour of such a course, although, possibly, the details might be somewhat modified to advantage. The nomination of members after the list has been published by the Council is obviously undesirable, as it gives rise to an idea of antagonism to the Council. A much better course would be that any nominations, properly supported, should be sent in to the Council by a certain date, and that any such nomination *must* be published in the balloting list. At present, suggestions may be made to the Council; but it does not follow at all that they are accepted. If formal nominations were made, the Council might then extend the list if desirable, and the complete list would be issued for ballot. In many ways it would be an advantage to have the names of the proposer and seconder given after the name of each candidate, but this is only a matter of detail. If outside nominations became general it would be almost essential to have more candidates than vacancies, otherwise a ballot would be meaningless. In any case the aim of any such movement should be, as Mr. COWAN points out, to ensure the harmony and vitality upon which the well-being of the Institution so largely depends.

The Electrobus.

IN view of the passing of the horse omnibus, it is to be greatly regretted that the electrically-successful line of omnibuses (the "Electrobus") has, from purely financial reasons it appears, been taken off the London streets. These omnibuses were really a boon to the public. Clean and sweet, free from oil and dust, and running without rattle or noise, they had already become popular, and they might possibly have taken a prominent place in our principal thoroughfares if they had had a fair chance. In the interest of electric traction it would be well if the Electrobus venture could be exploited actively by a body of commercial men who would conscientiously develop this side of the electric vehicle industry. Now that it has been shown that the electrobus is a possible competitor with other vehicles on the streets, it is most desirable that the potentialities of the service should be brought home with emphasis to the public mind. Owing to the peculiar tactics of those who have hitherto handled the problem, the public has come to regard the electric vehicle as out of the running where public service is concerned, and in this way a branch of the electrical industry has been not only nipped in the bud, but somewhat discredited.

Direction of Motion of an Electron.—A Paper on the direction of motion of an electron ejected from an atom by ultra-violet light was read before a recent meeting of the Royal Society by Mr. R. D. Kleman. Experiments were carried out to see whether the cathode radiation from substances exposed to ultra-violet light moved initially in the direction of propagation of the light. The amount of cathode radiation from a platinum film, deposited on a quartz plate in a discharge tube, was measured with the film facing the source of ultra-violet light, and with it facing in the opposite direction. It was found that if the intensity of the pencil of light used was denoted by unity, the intensity of the light after passing through the quartz plate and film was 0·55; and if the intensity of the cathode radiation from the film when it faced the source of light was denoted by unity, the intensity of the radiation when the film faced in the opposite direction was 1·15. Since the intensity of the light decreased as it passed through the quartz plate and platinum film, it followed that the larger leak in the latter case than in the former would not be obtained if the cathode rays were ejected equally in all directions, but might occur if they had a component in the direction of propagation of the light.

Obituary.—L. V. Lewis.—We regret to announce the death, on June 4th, of Mr. L. V. Lewis, who was for many years closely identified with the management of the "Observer" newspaper (London) and for several years its actual manager. He was also on the clerical staff of The Electrician in its earlier years. Mr. Lewis resigned his position on the "Observer" in 1898 and retired, more or less, into private life, continuing only his correspondence with several of the principal Continental journals. He was born at Boulogne-sur-Mer in 1844, was educated chiefly in England, and early in life commenced his connection with the press. He was a skilled writer on many subjects, an extreme Radical in politics, and for many years a well-known member of the National Liberal Club. He leaves a wife and son to mourn his loss.

Catalogue of Scientific Apparatus at the Brussels Exhibition.—The international exhibition which is now being held at Brussels is the first which has been directed by the Exhibitions Branch of the Board of Trade. It is not, therefore, without interest to see how this new department is shaping and what steps it is taking to keep up British prestige. On one part of its work it may certainly be congratulated, even at this early stage. It nominated a Liberal Arts Committee, to a sub-committee of which fell the task of organising the exhibit of philosophical instruments. In connection with this exhibit a very detailed catalogue has been compiled, which it is hoped may be of permanent value from the reference point of view. This catalogue has been edited by the National Physical Laboratory, under the supervision of Mr. E. H. Rayner, and contains well illustrated descriptions. To describe the various exhibits, advantage has been taken of the articles which appear from time to time in the technical and scientific journals, abstracts being made from them for the purposes of this catalogue. We are pleased to see that electricity in its measurement and applications is the branch of science most largely represented, the exhibits of the Cambridge Scientific Instrument Co. and Mr. R. W. Paul being typical of the wide range covered. Prices have not been included, but it was felt that sufficient space could not be spared for complete prices, and that incomplete prices would only be misleading. Information of this kind will be given by Mr. Danmatt, who has the catalogues of the various firms for distribution. Special value attaches to the bibliography accompanying this section, and Mr. Rayner may be heartily congratulated on his share in the work.

An American Telephone Company and the Death of King Edward.—According to the "Electrical World," every person who called up any exchange of the Chicago Telephone Co. on May 6th between 6 p.m. and 10 p.m. was given this message without solicitation by the operator: "King Edward died at 11:45 p.m." The difference in time between London and Chicago accounts, of course, for the difference in the hours named. So many inquiries were received earlier in the day in relation to the dying king that a general order to operators to make the announcement was issued as soon as the king's death became known. In this way the news was carried to thousands of persons.

Paralleling Large Alternating Current Systems.—In a recent issue of the "Electric Journal" Mr. P. M. Lincoln discusses the problem of transmitting energy from one alternating-current system to another. The chief results of the discussion are as follows: Two alternating-current systems should not be connected together by a transformer or synchronous-motor-generator set having a rating smaller than 50 per cent. of the smaller system. If a transformer or synchronous-motor-generator set be used between two alternating-current systems, the only method of regulating the amount of power taken through such a connecting link is to control the power output of the prime movers of one or both systems. With sudden fluctuations in load, accurate or rapid control of the energy interchanged when using such a connecting link is practically impossible. The proper method of exchanging energy between two alternating-current systems is by the use of motor-generator sets, one at least of whose elements is an induction machine. When using an induction motor as one of the links, the alternating-current system that receives power must operate normally at a frequency somewhat lower than the generator end of the connecting link would generate were the set synchronous at both ends. The number of possible pole combinations that may be used in connecting a 60-cycle and 25-cycle system is limited and the choice of combination should depend on the direction in which energy is to be transferred.

Double Catenary Construction in Tunnels.—The "Electrical World" gives an account of a method of supporting double-messenger catenary trolley systems for use in tunnels, under bridges and in other places where the overhead space is limited. This construction provides a means of insulating the trolley conductor from its supporting messenger cables, which are in turn insulated at their points of suspension. The practice has previously been to treat both the messengers and trolley as electrified conductors, but the necessarily close proximity of the charged messenger to the earthed roof of tunnels and covered structures makes this construction unsatisfactory in those places. For continuing double-catenary trolley through tunnels and under bridges the trolley conductor is carried in a clamp which is in turn seated in a roughly-triangular treated-wooden clamping block which grasps the catenary messengers. A short pipe section between the clamping block and trolley car provides an adjustable link which permits allowance to be made for the catenary curve of the messenger. The messenger cables are in turn supported and insulated by structures comprising suspension pipes and a cross-piece carrying a fluted insulating collar which seats the suspension cables firmly in position. The cross-piece is not threaded into, but passes through the T-fittings, being held in place by cotter pins. This construction enables the cross-pipe to be put up or taken down after the supports have been installed, in case repairs become necessary.

Thermit Welding and Motor Repairs.—According to the "Electric Railway Journal," the Virginia Railway & Power Co. has been very successful in repairing motor casings by thermit welding. For the repair of the broken half of a motor case, the Company uses a mixture of 25 lb. to 35 lb. of thermit and 10 lb. of steel shavings. The pre-heating is done with a compressed air-gasoline torch. The cost for repairing a "half" is about £3, whereas a new half costs £18. This repair-cost includes the expense of gasoline and labour, but not the depreciation on appliances, or the compressed air

Digitized by Google

which is available throughout the shop. About three to four gallons of gasoline are used per weld. The labour charge is 12s., and is made up of the day's work of two men at 6s., who carry out the complete process from the making of the moulds to the chipping of the case. The low cost for labour shows conclusively, our contemporary thinks, how little skill is required in this method of welding after the men have had a little experience.

Method of Renewing Carbon Filament Lamps.—A recent issue of the "Engineer" describes a method for renewing carbon filament lamps which has come into being in Germany. The lamp to be treated must have its filaments unbroken. The top of the lamp bulb is opened, and a tube is fused to it at this point. The bulb is then sufficiently heated to burn off the carbon deposit. A small amount of some suitable hydrocarbon is then introduced into the bulb and a vacuum produced. Current is passed through the filament, and carbon is thus deposited in a manner similar to that adopted in the ordinary flashing process. The cost is said to be about 2½d. per lamp.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

In our Marine Issue, which is incorporated with the present number of THE ELECTRICIAN, will be found a large number of articles, including the following: "The Future of Electricity on Ships," by A. P. Chalkley; "Marine Propulsion by Electric Motors," by H. A. Mavor; "A System of Turbo-Electric Propulsion of Ships," by H. C. Leake; "Electrical Marine Propulsion on the Paragon System," by W. P. Durtnall; "Electro-Mechanical Propulsion with Diesel Engines," by Eng.-Lieut. W. P. Sillince; "Electrically-Driven Shipyard Cranes," by H. H. Broughton; "Switchboards on Warships," by A. G. Collis; "The Wiring of Ships," by G. Austin; "Electric Steering Gear," by A. P. Chalkley; "Ship Illumination and Fittings," by G. Austin; "Searchlight Projectors for Marine Purposes," by E. A. Holmes; "Ships' Telephones," by H. S. Thompson; "Wireless Telegraphy for Marine Intercommunication," by W. W. Bradfield; and "The Use of Electrical Power for Auxiliary Purposes on Board Ship," by J. A. Seager.

We give a translation of Count Arco's recent lecture on "Some Experiments with the New Telefunken System," delivered before the Verband Deutscher Elektrotechniker.

The adjourned discussion on the comparative effects of Free Trade and Protection upon the electrical industry was concluded on Monday last. We give an abstract of this.

We also give an account of the discussion on Mr. G. W. Worrall's Paper on "Commutation Phenomena and Magnetic Oscillations Occurring in Direct-Current Machines," read recently before the Birmingham local section of the Institution of Electrical Engineers.

Bethnal Green (London) Council have now decided to enter into an arrangement with Shoreditch Council for a supply of electricity in bulk.

A proposal is under consideration for constructing an electric tramway between Maidstone and Chatham, a distance of about 7 miles.

An inquiry was held on Tuesday into the application of Sheffield Corporation for permission to borrow £78,207 for additional generating plant, &c.

Extensions of the electricity undertaking at Rotherham are projected, at an estimated cost of £27,832.

Northampton Corporation propose to extend their tramways to Far Cotton, at an estimated cost of £14,560.

West Bromwich Corporation are applying for sanction to a loan of £11,386 for extensions of their electricity undertaking.

Frome Council have decided to transfer their electricity undertaking to Edmundson's Electricity Corpn.

An inquiry was held at Coventry on Wednesday into the application of the Corporation for permission to borrow £54,200 for electric lighting extensions.

INSTITUTIONS AND SOCIETIES.

INSTITUTION OF ELECTRICAL ENGINEERS.—The annual Conversazione is to take place on June 28th at the Natural History Museum, South Kensington.

INSTITUTION OF MINING ENGINEERS.—At a recent meeting the list of awards for Papers read before the Institution was announced. Mr. Robert Nelson, H.M. Electrical Inspector of Mines, receives a premium for his Paper on "Electricity in Coal Mines."

THE ROYAL SOCIETY.—In addition to the meetings announced for the current session, an ordinary meeting will be held on Thursday, June 16th. Among the Papers read at the meeting of this society yesterday afternoon were the following: "The Distribution of Velocity in the β-rays from a Radioactive Substance," by Mr. J. A. Gray; "The Decrease of Velocity of the β-particles on Passing through Matter," by Mr. W. Wilson; "Rate of Emission of α-particles from Uranium and its Products," by Mr. J. N. Brown; "The Accumulation of Helium in Geological Time.—IV.," by Prof. the Hon. R. J. Strutt, F.R.S.; "The Effect of Small Traces of Water Vapour on the Velocities of Ions produced by Röntgen Rays," by Mr. R. T. Lattey; "The Effect of Pressure upon Arc Spectra, Part II., No. 4.—Gold," by Dr. W. G. Duffield, and "On Radiation in a Gaseous Explosion," by Prof. B. Hopkinson, F.R.S.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, June 11th.

ROYAL INSTITUTION.

3 p.m. Lecture on "Electric Heating and Pyrometry," by Prof. J. A. Fleming, F.R.S. (The Tyndall Lectures.) (Lecture II.)

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

TUESDAY, June 14th.

10 a.m. Convention opened by the Lord Provost of Glasgow (the Hon. A. McInnes Shaw) in the Rankine Hall of the Institute of Engineers and Shipbuilders in Scotland. Presidential address by Mr. W. W. Lackie (Chief Electrical Engineer, Glasgow Corporation Electricity Department). Papers on "Commercial Progress," by Messrs. A. C. Cramb (Chief Electrical Engineer, Croydon) and H. Collings Bishop (Chief Electrical Engineer, Newport, Mon.).

3 p.m. Visit to the (*a*) Springburn Sub-station of the Electricity Department; (*b*) Pinkston Power House of the Tramways Department; (*c*) Port Dundas Electricity Works of the Electricity Department.

7:30 p.m. Reception and Conversazione at the City Chambers by the Lord Provost, Magistrates and Town Council of the City of Glasgow.

WEDNESDAY, June 15th.

10 a.m. Meeting in the Free Gardeners' Hall, Picardy Place, Edinburgh. Papers on "Exhaust Steam Turbines and Condensing Plant," by Mr. F. A. Newington (Chief Electrical Engineer, Edinburgh), and on "Mixed Pressure Turbines," by Mr. Ashton Bremner (Chief Electrical Engineer, Burslem).

1:15 p.m. Luncheon at the Music Hall, George-street.

2:30 p.m. Visit to the Works of the Electricity Department, Macdonald-road.

THURSDAY, June 16th.

10 a.m. Meeting in the Rankine Hall of the Institute of Engineers and Shipbuilders, Glasgow. Discussion on "Advantages of Continuous Records of Costs and of Steam Consumption," opened by Mr. G. Wilkinson (Chief Electrical Engineer, Harrogate) and Mr. C. E. C. Shawfield (Chief Electrical Engineer, Wolverhampton); and on "Cheapening of the Cost of Mains and Services," opened by Mr. S. E. Fedden (Chief Electrical Engineer, Sheffield) and Mr. S. J. Watson (Chief Electrical Engineer, Bury).

1 p.m. Luncheon at the Grosvenor Hotel.

2 p.m. Visit to (*a*) St. Andrew's Cross Electricity Works of the Electricity Department; (*b*) Coplawhill Works of the Tramways Department; (*c*) Electricity Works of the Govan Electricity Department.

Alternative series of visits.

(*a*) Electricity Works of the Partick Electricity Department;
(*b*) Power Station of the Clyde Valley Electric Power Co. at Yoker;
(*c*) The Shipbuilding Works of Messrs. Beardmore (Ltd.), Dalmuir.

7 p.m. Annual Dinner at the Windsor Hotel.

FRIDAY, June 17th.

10 a.m. Annual General Meeting in the Rankine Hall of the Institute of Engineers and Shipbuilders, Glasgow.

1 p.m. Luncheon, Grosvenor Restaurant.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, June 13th, "A" Company.—Recruits Infantry Drill 6 to 6:45 p.m. Technical Drill 7 to 9:30 p.m.

Tuesday, June 14th, "B" Company.—Recruits Infantry Drill 6 to 6:45 p.m. Technical Drill 7 to 9:30 p.m.

Wednesday, June 15th.—Gymnasium 6 to 9:30 p.m.

Thursday, June 16th, "C" Company.—Recruits Infantry Drill 6 to 6:45 p.m. Technical Drill 7 to 9:30 p.m.

Friday, June 17th, "D" Company.—Technical Drill 6:30 to 9:30 p.m.

ELECTRIFICATION OF FERNDALE COLLIERIES.

The Paper on this subject, read by Mr. W. H. Patchell before the South Wales Institute of Engineers, and of which an abstract appeared in our issues of October 29th and November 5th, 1909, aroused so much interest that the discussion was twice adjourned. We give below an abstract, from the "Proceedings" of the Institute, of the remarks of the various members who contributed to the discussion.

The PRESIDENT, in opening the discussion, asked the reason for taking the water from the lodge rooms right down the pit to the pumps at the bottom and pumping the water up again. In connection with the ventilation a number of years ago he had made experiments on fans and was inclined to think that Mr. Patchell had been misled in taking the velocity at the top of the chimney. It was no easy matter accurately to measure air, but the figures given in the Paper seemed to him to impugn the reliability, at any rate, of the figures taken at the top of the chimney. He also asked Mr. Patchell to explain why the pressure of the motor placed in the return was reduced from 2,200 volts to 440. He thought 440 volts would be just as dangerous if the return air was in an explosive state.

Mr. D. HANNAH, with regard to the latter point of the President, said the electrical rules would not permit of greater voltage in return airways than medium pressure. Then with respect to placing one pump at the pit bottom instead of in the lodge rooms, this method obviated the winding of water from sumps at two pits and also the sinking of men to lodge rooms. It saved boiler power, and the whole of the work was done with one man at the electrical pumps at the bottom with one plant.

The PRESIDENT asked why not put the electrical pump in the lodge room?

Mr. HANNAH, continuing, said with the electrical work they had done away with boilers and with one engineman, and the whole of the water was taken down to one common centre. If the electrical pumps were in the lodge room an everyday inspection would be necessary, and a winding man and stoker would be required.

Mr. A. DAVIES (communicated) thought Mr. Patchell could have bought turbo-generators and condensing plant in which he could have placed as much reliance as in the plant installed; and the complete turbo-generating plant could probably be erected on the same floor space as one of the existing sets. A further point in favour of the turbo-generator was that the turbine and alternator were mounted on a combination bedplate; this was of great importance where the possibility of subsidence was present. As to the switchboard, switchgear could have been obtained which would have occupied about half the space and could be operated with the same degree of safety and certainty of action. The "switch-wagon" type of board was as safe, more easily erected and more economical of space and building work, the inspection of its component parts could be carried out with absolute safety, and the operator had only low-tension gear to handle. The haulage gears appeared to be well designed. The motors were all of the "end shield" bearing type; he preferred motors, for the two larger sizes especially, with low pedestal bearings and feet on the stator frame: this arrangement with a good baseplate for motor and gear lent itself to great stability. The "end shield" type of motor did not allow of any adjustment of the air-gap, and, further, the shields must make it awkward to inspect and test the air-gap. As it was quite good practice to make air-gaps as fine as possible, they necessarily ought to be inspected at least once a week. The controllers appeared to have been designed with a view to durability alone. This desire had evolved an expensive and intricate arrangement. He agreed with the principle, but suggested that the controller and reversing switch should be on one spindle, the movement of the handle being simply backwards and forwards, with a catch for the "off" position. The tramway type and the liquid type regulator, when properly designed, had a field for haulage work; and where the latter could be used it would be found to give a smoother starting effort, and this effort could be made independent of the engineman. He asked for information as to the life of the belts of the pumping plant. Would it not have been possible to have had pumps running at about 1,480 revs. per min., with an extra couple of stages and to use direct-coupled motors, instead of driving by belt? As to the winder, the Ilgner dynamo and the winder motor fields were excited by a motor-generator. This meant that in the event of a failure of the supply the winder would stop almost at once. With the A.E.G. Ilgner winders this did not take place, as the exciter dynamo was mounted on the same shaft as the flywheel motor-generator; and in the event of the supply failing, the winder motor could be run until the flywheel was unloaded, allowing of several winds. He believed the A.E.G. were the only firm who built the exciter dynamo on the motor-generator shaft. Other makers had a separate motor-generator and employed a battery as a stand-by. A slip regulator of the liquid type would probably give better results on account of its smoother action. Altogether about 240 Ilgner winders had been installed all over the world. He thought that Messrs. Siemens, Schuckert and the A.E.G. had made about 100 each, and the Lahmeyer Co. about 40. The direct three-phase winder was, in his opinion, a simpler solution of the problem; and in South Wales, with a public supply company, there should be no question of their adoption. Even if the question of increase of generating plant should crop up, it might be solved by putting the winder on the supply company's mains.

Mr. F. G. MAGUIRE referring to the President's statement that the author's readings of the air flow were incorrect, because the velocities at the centre of the discharge area should have been the highest, as was always the case with water or air flowing through pipes, said that an evase discharge chimney could not be considered to be the same as an ordinary pipe through which air or water was flowing. In some cases, more particularly where the fan was not working on full load, the velocity of flow at the centre of the top of the discharge chimney was considerably lower than at the sides; and in all cases the air had a tendency to follow the inclined side of the chimney. In some extreme cases he had even recorded a return current or down draught in the centre of the chimney. He felt perfectly satisfied that the figures given were as nearly correct as it was possible to get.

Mr. B. J. DAY said he had visited colliery installations in the Belgian coalfield and in Westphalia, and so far as the power station was concerned, he had never seen a better carried out installation, so far as the general design was concerned, than that at Tylorstown. It had been carried out practically on the same lines as many of the largest municipal installations in this country. Whether this was the point of view from which to carry out a colliery installation was another matter. He doubted whether engineers were right in spending so much money as in the installation under notice. The whole idea seemed to have been to instal plant to produce a unit of electricity with the smallest possible coal consumption. Mr. Patchell remarked that a unit of electricity was obtained for 17 lb. of water pumped into the boilers. The fuel used was worth only 5s. 8d. per ton, and therefore he would have been justified in not going for such a high coal economy and in reducing the capital charges. 9,000,000 units per annum, using two sets running and one standing, was equivalent to a load factor of 34 per cent.; the capital charges, therefore, represented 0·272d. per unit. This was equivalent at 10 per cent. per annum to £102,000 and at 15 per cent. to £68,000—a very large expense for any colliery company to incur. Mr. Patchell could have obtained absolutely the same results, so far as efficiency and reliability were concerned, if he had put down a first-class turbo-generating plant, and the cost would have been approximately about one half. Turning to the boiler plant, Mr. Patchell had got an efficiency of 79 per cent.—an extremely high figure. His CO_2 percentage, 13, was very good, but the heat of his gases at the base of the chimney was 478° F., and that of the feed water only 118 deg. If he was going for economy, it would have paid Mr. Patchell to have put in an economiser and brought up the feed-water temperature to 200 deg. or 250 deg., especially with induced draught plant. The necessity of installing a battery of accumulators was not apparent. Mr. Patchell had assumed a power factor of 0·85. Where the bulk of the plant was large slow speed haulage motors a closer figure would be 0·75; this would have the effect of reducing the capacity of the generators from 1,600 kw. to 1,400 kw. Again, it was stated that the operator in the ordinary course of his work only had low-tension gear to handle. This must be an error, as all switchgear was high tension, and was operated from a platform above by means of a rod. There was another point about Mr. Patchell's switchgear which could be improved upon, namely, the disconnecting links operated by means of hooks attached to wooden handles. A better method was to have these disconnecting links operated by a switch-handle as in the case of the oil switch, and these handles should be interlocked with the oil switches, so that the operator could not open his isolating links until he had opened his oil switch. With regard to the transmission line, the most distant point from the power station was only 2½ miles and the bulk of the power was only transmitted 1¼ miles. It was not stated what power was transmitted, but allowing for some transformers as spares, it was about 1,000 kw. A 0·1 sq. in. three-phase line transmitting 100 amperes—*i.e.*, 250 kw. to 300 kw.—would cost about £600 per mile, and at a rough estimate the cost of transformers and sub-stations would be at least £3,000, or more than it would have cost to have put up 2,000-volt lines throughout and a spare line. This would have simplified the whole scheme by keeping to one not excessive pressure—2,000 volts—and the trouble arising from surging, &c., need not have been expected. A 2,000-volt installation was more easily handled than a 6,000-volt installation. As to the return airways, if it was considered quite safe to instal 440-volt motors, why not instal 2,000-volt motors?

Mr. TRUMP, H.M.I., here remarked that it was not permissible to use higher than medium pressure in return airways.

Mr. DAY, continuing, said his point was: Mr. Patchell was on the Commission appointed to draw up these regulations, and if he put a motor there at all, why limit himself to 440 volts? If there was danger in the return airways with electric motors, they should be prohibited altogether, there was as much risk with 400 volts as with 2,000 volts. Referring to the power of the new haulage gear, Mr. Patchell had stated that in the case of a journey having run wild on an incline, the resultant heap at the bottom was not laboriously cleared up by a breakdown gang, but the haulage rope was attached to the top tram and the heap drawn out by an application of two or two and a half times normal torque into something like order, which very considerably shortened the time during which the road was blocked. The speaker considered this was an extraordinary thing to do. He asked what happened to the circuit-breakers or his cut-outs. If these were set high enough to bring a full journey back on to the road as described, they were useless to protect the haulage under working conditions. Such a practice ought to be condemned in the strongest possible manner. It was only encouraging the overloading of ropes and haulage gears. Unsuitable wheels had been a great drawback to electrical haulage underground. Firms were making a speciality of electrical haulage wheels, so that they could run with a motor speed of 360 revs. per min. with only a single reduction. With such wheels, a higher efficiency was obtained not only in the wheels themselves, but also in the motor, as well as a higher power factor. The design of Mr. Patchell's haulage gears was absolutely wrong. The motor was put on

Digitized by Google

a separate bed from the haulage gear, and a flexible coupling had been introduced between the haulage motors and gears. He was bound to do this because the design was wrong, and entailed an enormous width of haulage chamber underground. The cost also was excessive. But apart from these considerations, the haulage motor and the gear should be one combined machine. The width of the 100 H.P. gear was 21 ft., but if designed on the plan he (Mr. Day) suggested, the overall width would be about 11 ft. 6 in. to 12 ft. As to controllers, he did not see that the arrangement was novel or why it was called "Patchell's System." For many years Continental makers had used two-phase rotors for haulage work so as to simplify connections. English makers had been slow to follow suit, but they were at length taking a wrinkle from the Continental practice. Again, he thought the figures for power factor of the haulage motors were manufacturers' figures, and off-hand he should say they were impossible.

Mr. I. V. ROBINSON said that Mr. Patchell had worked out the load factor upon the maximum load, whereas it should be taken upon the total capacity of the plant, as it was upon this capacity the total charges were based. The speaker next worked out the cost per kilowatt of plant installed as £14. 3s. If the plant was installed primarily to secure high economy, he asked why did not Mr. Patchell pay a little more and put in a gas-engine installation, which could be put down at from £16 to £17 per kilowatt? He did not think Mr. Patchell had got a sufficiently great economy to make anyone anxious to put in a similar installation. The weight of the engines was 155 tons each, and generators 107 tons, or 262 tons per set. A turbo for this output would weigh, approximately, 35 tons, and generator about 25 tons; total, 60 tons per set, or a saving of 202 tons of material on each set. This should represent a considerable saving in cost. Then the space occupied was also about double, so that the cost for engine house and foundations would certainly be less than half in the case of the turbo.

Mr. D. HANNAH remarked that he was entirely responsible for turbo-generators not being used, as three or four years ago, when the scheme was under consideration, he thought turbo-generators too risky to put down for colliery work. His opinion now might possibly be modified. The placing of the motors outside the haulages, described by Mr. Day as a clumsy arrangement, was also due to the speaker, but if the work had to be done again he should adopt the same method. He visited several collieries in South Wales, the Midlands and the North of England, and came to the conclusion that single-reduction haulages were the best system to adopt. This necessitated very large motors, and as it was desirable that the engineman should have a clear view of his haulage gear, it was decided that the motors should be placed alongside the haulages instead of in front of the engine In later designs the motor was put on a bedplate attached to the haulage set. He must exonerate Mr. Patchell from any blame with respect to the arrangement, if blame were merited.

Mr. C. W. JORDAN asked if there was any explanation of the comparatively high steam consumption of these engines. He had occasion a few months ago to go into the question of installing engines of about 2,000 H.P. and he was offered plant guaranteed to work at 8½ lb. per indicated. horse-power hour. He had particulars of a test made on a 1,500 H.P. Carels Freres tandem compound engine at the paper mills of Messrs. Edward Lloyd, at Sittingbourne, Kent. The steam consumption on two-thirds load worked out at 9·6 lb. per indicated-horse-power hour, compared with 11·5 lb. at Ferndale—*i.e.*, a saving of about 16·7 per cent. He also asked why did not Mr. Patchell generate at 6,000 volts instead of 2,000. He might add that the Carels Freres engine cost somewhat less than the Sulzer engine.

Mr. H. RICHES JENKINS said in choosing a controller for use at his colliery installation he selected Mr. Patchell's mainly because of its accessibility.

Mr. T. SUGDEN said the 8½ lb. steam consumption mentioned by Mr. Jordan was a very extraordinary figure, and indicated a result not likely to be obtained under normal working conditions. Results of that kind should be verified by an independent expert before being fully accepted.

Mr. C. W. JORDAN replied that he had a quotation from Carels Freres guaranteeing him a steam consumption of 8½ lb. per indicated horse-power hour under a penalty.

Mr. C. B. CHARTRES asked for further particulars of the working conditions. With regard to the figures given concerning the testing of the fans, he considered it doubtful if the outputs calculated from the velocities measured in the Evasé chimney could be relied on. His experience was that much more reliable results were obtainable if measurements of the air were made on the suction side of the fair, as it was possible to work with smaller velocities, and the danger of eddies upsetting the readings was not so great.

Mr. W. O'CONNOR stated that he had taken part in many fan tests and had found in the case of the larger chimneys of the older types of fans, without exception, that the higher velocities were in the centre of the chimney and the lower velocities along the outer divisions. He also suggested, in connection with the example in the Paper, a method of reducing the loss to a much smaller figure. As far as he could ascertain from the Paper, the angle of increase, or "flare," if he might use the term, was about 1 in 6½ along the spiral of the fan, but in the cone—the straight part of the chimney—it was about 1 in 4½. The results seemed to point out that this increase was not sufficiently rapid, or, possibly, a uniform rate of increase was not the best method. He would say that if the area of exit was increased more rapidly, say, to 12 ft. by 10 ft., and the velocity of efflux made fairly uniform, the loss, with 116,087 cubic ft. per minute would be exactly 1 H.P., showing a saving of about 3 per cent., if eddies could be removed from the present chimney, and more as compared with present conditions. Again, the tractive co-efficient was high, and he could only suggest that the weight, nearly two tons, was, perhaps, a little more than was usually carried on a pair of 2 in. axles.

Mr. W. H. PATCHELL, replying to the discussion, said he had made a number of tests on Evasé chimneys, and found, as Mr. MaGuire stated, that there was always a higher velocity on the inclined side of the chimney and a lower velocity in the centre. He quite agreed with Mr. Hannah that turbo-generators were too risky at the time the plant was projected. They had passed through many stages of development, and the machine now available was very different from that four or five years ago. Mr. Davies had leaned to the waggon type of switchboard. The author had not found that the floor space occupied gave any advantage over the type which he had adopted, and, further, he did not consider that the type was safer than the existing type. Some makers, in his opinion, unduly cramped the switchboard arrangements, and it had been his lot to redesign more than one board which was built on lines proved to be perfectly safe in connection with some supplies, but proved to be quite unsafe in connection with other supplies with high power behind them. Both the tramway and liquid type of controller were in his (Mr. Patchell's) opinion, unfitted, as offered, for work on underground conditions. The tramway type had proved most expensive in repairs, and both it and the liquid type required constant attention. It was because he was not satisfied with the available controllers that his controller was developed. He informed the meeting that the owners were thoroughly satisfied with the arrangement, that the repairs and attention required were practically nothing, and that not a single journey had been lost by faults on either the haulage gears or controllers during over four years' work. The advantage of mounting the exciter dynamo on the Ilgner flywheel shaft had had his consideration for some time. It promised to be quite satisfactory for a wind or two, but as the speed of the flywheel fell the speed of the direct-coupled generator was not sufficient to give the proper voltage required for the field circuits, so that although the supply was certainly not cut off suddenly, as in the case of a separate motor generator, it was not possible with the arrangements to get the full value out of the flywheel. The adoption of a three-phase motor for the winder had his very serious consideration. The operation of examples of this system that he had seen were certainly not such as would be permissible on the public supply company's mains in South Wales. The suggestion that the breakdown of the fan might have been avoided if pedestal bearings instead of end shields had been used was unfortunate, as the motor in question was fitted with pedestal bearings, and not with end shields. With regard to working costs, Mr. Davies compared costs given by Mr. Sparks of the Aberaman plant with the costs given of Ferndale. The great difference appeared to be in interest and depreciation on capital. Mr. Sparks stated in the Paper referred to that the plant was started in 1905. He (Mr. Patchell) was informed some time ago that the plant had been shut down and superseded; so that possibly it was put in with a view to a particularly short life; but in any case the figures quoted by Mr. Sparks hardly covered obsolescence in five years. The glazed bricks at Ferndale and some other details which were thought too lavish were adopted after full consideration by the board of directors, who were now good enough to say that they were quite satisfied that the expenditure had been economical and had repaid for itself. In a colliery district subsidence was much more likely to occur than elsewhere, hence good sound work was more than ever necessary. He would again repeat that plenty of light and elbow room round machines made for easier and better maintenance. The reason that he did not put in an economiser was because he considered it would not pay. On the other hand, the small battery of accumulators was extremely useful in the early stages of the development of the station, and was still useful as an insurance against interruption of the field circuits. As regards handling high-tension gear, it was a little difficult to follow Mr. Day's comment. There was all the difference between handling parts which, when metal, were earthed and were far removed from high-tension parts, and the juxtaposition of the switch operator to a high-tension switch and the necessary connection. A scheme for a 2,200-volt transmission was turned down on account of various objections. A total of 3 sq. in. area of copper would have been necessary; the difficulty of supporting it, the space occupied if the circuits were sub-divided into sizes which could be reasonably handled, and the expense, in view of the then high price of copper. With reference to the relative safety of medium pressure and higher pressures, his experience during the last 10 years with pressures up to 10,000 volts led him unhesitatingly to say, as he had often said before, it was easier to control the volts than the amperes. He believed that in due time this would be more generally recognised. Mr. Day suggested that he was considerably overloading the haulages and teaching the attendants bad habits. The details given in the Paper showed that the maximum torque was twice the normal torque. The 2½ times normal torque referred to some special haulages which were built on those lines. There was no question of overloading. The basis of calculating load factor that he had used had long been recognised by engineers as the standard upon which annual tables of costs, &c., were made out. In reply to Mr. Jordan he would state that although he had heard of the test referred to he had not seen particulars. There was no such practical difference in the design of the Carels and the Sulzer engines as would account for the figures mentioned. The essence of the Sulzer efficiency was in the form of valve adopted and the small clearance thereby obtained; this was common to both makers. He felt sure that the difference could only be accounted for by the environment of the engine and the conditions of the test. As regards the generation of the current at Ferndale at 6,600 volts instead of 2,200, and Mr. Jordan's suggestion that it was more economical to step down than to step up, so far as his experience went there was nothing in it, but he quite agreed that it was as safe to generate at higher pressures as at lower.

The Applications of Electrical Engineering to Marine Work.

It has been rightly said that this is an age of explanation. Every man, and woman too for that matter, whose actions obtain some public recognition feels called upon, in season and out of season, to offer excuses or confirmatory details for such and such a course of behaviour, and to point out that a particular muscular effort has been occasioned by a certain grouping of brain cells at a psychological moment. And, therefore, so as to be in the fashion, we feel that we must offer a few words of explanation for the distended appearance of this particular Friday's issue.

In the race which inevitably occurs between the technical journal and the text-book both suffer under disadvantages. The first because its information on a given subject is scattered, the second because its information is out of date. In the MARINE ISSUE of THE ELECTRICIAN we have tried, as we have tried before, to sweep away both these drawbacks; to lay before our readers an account of electrical engineering applied to marine work which shall be both concentrated and up to date and to erect a platform which shall serve as a foundation for building to greater heights.

The subject is of quite natural interest. So much of our country's welfare is bound up with the sea that even the non-technical reader will be able to appreciate the meaning of many of the articles in the following pages. For the technical reader the interest will be enhanced. He will find that while we have still worlds to conquer and progress to make, yet the electric drive has even now an assured position on shipboard, and is doing work which could not be performed so efficiently in any other way. The signed articles will indicate concisely the advances that have been made on the technical side, while in other columns individual manufacturers have an opportunity of showing what they have done in their particular specialities.

In this connection we may be forgiven for pointing out that the MARINE ISSUE of THE ELECTRICIAN appears at a very opportune time. The electric motor is, in practically every modern ship, receiving a wide application for the driving of the auxiliary machinery. For the operation of fans, hoists, capstans and all the other multifarious auxiliary equipment which finds a place on the present-day liner or battleship, the motor has ousted the less efficient steam plant. This is satisfactory, but we wish for more. Much trouble has been expended in the design and perfection of a system of electric drive for the operation of the main engines. The last few years have seen the old marine reciprocating engines replaced by the turbine, and we shall not be thought unduly optimistic, in some circles at least, if we prophesy that the next few years will see the steam turbine in its turn replaced by some system in which electrical machinery will play the chief part. The reasons for this expectation cannot be entered into here, but they are sufficiently discussed in other columns of this issue.

We expect then a great future for marine electrical engineering, but we must not forget that its present is not without merit. Each age has its chronicler, and we hope that in the days to come the MARINE ISSUE of THE ELECTRICIAN will be looked upon as no mean historian of the state of electrical affairs in marine work as they were in 1910.

The Future of Electricity on Ships.

BY A. P. CHALKLEY, B.Sc.

Summary.—It is pointed out that there are two tendencies at the present time in regard to the use of electricity on board ship; namely, either to use it for all purposes, or to apply it to every purpose except that of propulsion. The possibilities of the Diesel engine in this connection should be borne in mind. Producer plant has also been suggested, but the future in this line seems doubtful. On the other hand, the position of the turbine is assured. The standard voltage shows a tendency to rise, and there is much to be said in favour of alternating current in preference to continuous. A marked advance may be expected in electrical steering gear. Generally speaking, it may be said that the outlook for electricity on ships is very promising.

In attempting to foretell the future, one naturally looks to the past, and by deduction a fairly accurate idea of the minimum limit of possible developments is obtained—the minimum, because, particularly in the case of electricity, steady progress seldom diminishes, while, at the same time, important discoveries may at any moment give a hugh and unexpected impetus to its adoption.

The first ship to be equipped with electricity was the "Columbia" nearly 30 years ago, and the installation consisted of just over 100 10 c.p. lamps, and, in comparison with this, it may be stated that the electrical plant of the "Mauretania" comprises four generators with a total output of 1,600 kw. To maintain such a rate of advance in the future will tax the ingenuity of electrical engineers, and, if, as seems possible, the limit in size of ships is being reached, it can scarcely be anticipated that a corresponding increase in actual electric power installed will be more than realised. But it must be remembered that the "Mauretania" was to some extent a freak boat, as much in its way as the "Great Eastern," with the great difference that the one was successful and the other not, and the majority of the world's ships may be expected to adopt electricity on a very much larger scale in the next decade than they have in the last.

There are two tendencies with regard to the future of electricity at sea, one being towards its sole adoption as a motive power on ships, and the other its use for all purposes other than actual propulsion. The question of electromechanical propulsion is fully dealt with elsewhere in this issue, and need not be touched upon in this article except to mention that it is a development of the very near future, since no less than three separate systems will be put into practice within the next year, which serves amply as an illustration of the fact mentioned above that big strides may be made quite apart from the natural process of evolution. Were electric propulsion to become universal—which, however, its most ardent advocates do not anticipate—the progress of electricity on ships would be proportional to their increase in size and speed, but even without this there is a very wide field open for the economical employment of electric power at sea.

The adoption of electric propulsion would have little or no effect on the auxiliary electric machinery on ships. It might be thought at first sight that the main generating plant would be used for supplying electricity for all purposes, but it is probable for many reasons that such would not be the case. In the first place light is required at times when the ship is in port, and several motors are needed for ventilation, &c. Practically all ships at present use direct current, while the most promising aspect of electric propulsion is presented with the employment of alternating-current motors; but this will be discussed later. Moreover, were alternating current used for all purposes, the voltage would be different in the two cases which would necessitate inconvenient transformers or motor-generators.

It may safely be said that more than 90 per cent. of the existing electric generating plants on ships consist of reciprocating steam engines coupled to direct-current dynamos giving about 100 volts, which is equivalent to admitting that practically no advantage has been taken in the direction of cheap power production of which so much has been done on land in the last 10 or 15 years. There have, of course, been fairly substantial reasons for this attitude on the part of shipowners and shipbuilders, the chief being that economy of running has been scarcely considered, since the amount of steam used is small compared with that taken by the main propelling machinery. With the introduction of larger units, consequent upon the extended use of electricity, however, there is a tendency to pay greater attention to what has hitherto been considered a minor auxiliary, and there are signs that the reciprocating steam engine will, to some extent, be ousted from its monopoly. In some of the larger and more recently built battleships, Diesel engines, direct coupled to generators, have been installed, in conjunction, however, with the steam-driven plant of the old high-speed type. These engines have a very great advantage over steam engines on a small scale, as has been conclusively proved on land, though it must be admitted that the economy in working is more apparent than real when it is considered that exhaust steam is always useful for feed heating, and the capital cost of the boilers debitable to the electric generating plant is very small. There is another point of importance, however, namely, the fact that Diesel engines can be started up at very short notice, and may be run during the whole time a vessel is in port, thus obviating the necessity of having to fire boilers, specially for a small amount of electrical power. This is particularly noteworthy in the case of ships which lie up for a considerable portion of the year, or spend, say, a week in port and a week at sea, as many Atlantic liners, and there seems every prospect of a successful future for the mixed installation.

There are at present a good many advocates of producer gas engines for auxiliary drive, and though they would undoubtedly be a means of economy, it is somewhat doubtful if it is sufficient to warrant their adoption, since they cannot be started up so readily as the Diesel engines. They do, however, render the electrical generating plant independent of the boiler, which is a good principle, and it is possible that, under certain conditions of service, they might come into use.

Steam turbines of small size, both of the De Laval and Parsons types, have long been employed on ships—battleships, cross-channel steamers and liners—but they have, in most instances, only been used as auxiliaries to the main generating engines, in the case of battleships or, because of the very small space they occupy, for small boats, where the amount of electricity used is so small that lack of economy is of no importance. Should the size of ships increase largely in the future, and the electrical power needed likewise augment, there is every probability that turbines of moderate size (say up to 500 H.P.) will be used for generating. This has, of course, been done already on one or two ships, notably the "Mauretania" and "Lusitania," where four turbo-generators of 500 H.P. each were installed; and in very high-speed boats, where there is an enormous mass of machinery and so little available space, the turbine is likely to be preferred to the Diesel or other engine. The fact that practically no substantial foundations are required is a strong point in its favour, as is also its ready adaptability in running condensing, non-condensing and against a back pressure, when it is considered that these varying conditions are common at sea.

The question of voltage at sea and the future tendency in this direction is very debatable. Up to the present, or at any rate up to a couple of years ago, voltages of 100 were well nigh universal, and there has perhaps somewhat naturally been a timidity which caused shipowners to refrain from adopting a higher and more economical figure. The chief reason for this is the greater fire and personal risks involved, since it must be remembered that it is more difficult to maintain good insula-

Digitized by Google

tion at sea than on land, owing to the presence of moisture throughout the vessel. While the electrical installation on ships remained small, the saving to be effected in cables by the use of a higher voltage was scarcely sufficient for the question to be raised, but with the advent of very large equipments the matter is somewhat different. At 100 volts the cables become abnormally heavy, and, apart from the cost involved, they are very difficult to fix, and the system now adopted on most of the new British battleships is a three-wire arrangement with about 220 volts across the outers from which the power circuits are taken, and 110 across the inners for the lighting and some special circuits. It is very probable that as confidence is gained, and immunity from breakdown is seen, this will become much more common and even higher voltages will be employed, always provided that the wiring is carried out under most careful supervision—a point which it is impossible to emphasise too strongly.

It is curious that when electricity was introduced on ships nearly 30 years ago alternating current was employed, dropping into disuse almost immediately—particularly when electric power became a feature of the installation—while at the present time there is a very strong feeling in many quarters towards its rehabilitation. There is no use denying the fact, only too well known to marine engineers, that commutators are a nuisance—not to put too fine a point on it. Motors and generators receive practically no attention, and the former are extremely badly used. Starters are at the mercy of all and sundry, owing to the shortsighted policy of shipowners in limiting the electrical staff to the irreducible minimum, with the result that burnt-out armatures are almost the rule and not the exception. All this points to the advisability of the adoption of alternating current, with the consequent absence of commutators, and the employment of fool-proof motors capable of standing almost any treatment at the hands of incapable men. The objection, as regards the low starting torque of induction and synchronous motors, is not of great importance since most of the motors used at sea are employed for purposes where high starting torque is not essential, and in cases where considerable variation of speed is required special controllers can be used. As is the case with practically all questions of this sort, however, there is much to be said on both sides, and if we may predict that in the future alternating current will be extensively employed on ships, it need not imply that direct current will drop into oblivion; each system will have its use, and all will depend on the class of ship and the purposes for which electric power is required.

Mr. Durtnall has evolved a system of auxiliary drive with alternating current which may be mentioned in this connection as a possibility of the future which shows much likelihood of economical running and suitability for all conditions of service. The generator consists of an alternator and four or more rotating transformer generators mounted on the same shaft, driven by the prime mover, all of them being small, so that the length and weight are but little greater than with an ordinary machine of the same power. The number of ship's main circuits corresponds to the number of machines, and the regulators of all the motors on the boat are connected to each of them, so that power may be taken from any at will. If the current be taken direct from the alternator (that is, from its lead and the common return) the periodicity is a certain comparatively low figure; if the supply be taken from the first transformer generator, the periodicity is rather higher, since the current from the alternator has passed through the primary of the transformer generator, so that the direction of the rotation of the flux due to it is the same as the direction of mechanical rotation in the primary. The periodicity of the current taken from the secondary is, therefore, the sum of the two periodicities—that due to the alternator and that due to the transformer generator. This process is repeated through the remainder of the transformer generators, and a great range of periodicity obtained. All the motors can therefore be operated economically, speed and torque being varied by changing the frequency of supply without the introduction of wasteful and bulky resistances.

Most of the auxiliaries on ships have now been electrically driven though there are many in which this is most uncommon. Perhaps almost the only exceptions are the air pumps for the condensers and the boiler feed pumps. There is no reason why the former should not be adapted to electricity, as is common on land, and it is rather remarkable that this has not been carried out. It is notorious that all steam-driven auxiliaries are uneconomical in steam, and it is chiefly lack of confidence which has partially prevented their being operated by electricity. Circulating pumps for the condensing water are eminently adapted for electric drive, and the addition of these two most important auxiliaries to the electrical installation will have the effect of lowering the cost of production of electricity to a very considerable extent. Boiler feed pumps are not likely to be converted to electricity, and even in central stations on land they are almost invariably steam driven, the difficulty being the large range of speed required and the undesirability of the use of rheostats for obtaining the variation.

In England electrically operated steering gear is, except in the case of one or two small yachts, practically unknown, and it is in this field that great advances may be expected in the near future. The present method of steering by large and cumbersome steam steering engines operated by mechanical means is not fully satisfactory and the reverse of economical. An electrical system can so easily be safeguarded against breakdown without large additional primary cost that it would probably work out considerably more cheaply than the steam-driven gear which is frequently in duplicate on large ships. The ease with which ships could be steered from two or three points merely by taking wires to these places is an advantage upon which it would be difficult to lay too much stress.

There are many ways in which an electrical steering gear may be designed. Two methods are already in use on several Russian and American battleships, and there is little doubt that these, or modifications of them, will shortly become common throughout the world generally, both for battleships and for mercantile boats. One of these gears consists of two similar motors coupled together through differential gear between them, by means of which an increase of speed in either will cause the shaft operating the rudder through further gearing to rotate in a direction dependent on which motor is accelerated. Since the differential gear is between the two motors, the armature shaft of one of them is hollow, and the steering shaft working the rudder passes through it and revolves within it, being supported in bearings at each end. The variations of speed of the motors are obtained by simple switchgear, which can be installed at various points. In another system there are two similar rheostats, the contact arms being operated respectively by the steering wheel in the navigating house and the rudder, and are so connected that when the arms are in corresponding positions no current flows through the circuit. The navigating rheostat controls the current supplied from the ship's circuit to the exciter of a motor-driven dynamo, which delivers its power to a motor operating the rudder through gearing. On working the wheel in the navigating house the steering motor starts up and moves the rudder until the contact arm attached to it reaches a stop on its rheostat corresponding to that of the rheostat in the wheel house, when current ceases to flow and the motor stops.

In view of the revolution which the introduction of metal lamps has caused on land, and their great increase in economy, it might be supposed that these lamps would find ready adoption at sea, but this is not the case. In the ordinary way a very large number of lamps are broken on every voyage due to vibration, and it has been found inadvisable up to the present time to employ those of the metal filament type, since they are of course considerably more fragile than carbon lamps. But the construction of the filaments is every day being improved and their reliability becoming very much greater, and there is a distinct possibility that in the near future metal filament lamps may replace the older type, though it must be noted that on modern ships the power required for lighting is quite small compared with that needed for motors, and the consequent actual economy in steam is so small as only to warrant the change if the reliability is in no way impaired.

Electricity has a wide field before it on battleships, though it

Digitized by Google

must be admitted that the British Admiralty has been by no means conservative in the matter. Electric mounting for guns is still far from universal, though there are many undeniable advantages, and it is more than possible that the slight dissatisfaction in some quarters is due to an incomplete acquaintance with the best methods of usage. There is really very little doubt as to the future final adoption of electricity for all guns, and the fact that so many operations are required for each shot fired is a point in which hydraulic power is at a great disadvantage.

There is one question which must not be lost sight of in estimating the future possibilities of electricity at sea, and that is the necessity of educating marine engineers and impressing the fact upon shipowners that a large electrical installation cannot be left to run itself. It has in the past been all too common to have a totally inadequate electrical staff, and when the inevitable failure occurs—due to neglect—the fault is apt to be put down as inherent in electricity, whereas in most cases it is simply the result of imperfect supervision. Nothing could be more economical and reliable than electricity for nearly all the appliances at sea, but it is totally unfair to give it only half as much attention (and that often unskilled) as would be considered necessary if steam or hydraulic power were employed, and if the extension of the use of electricity at sea is to be as rapid in the future as we hope, this fact must be kept prominently to the fore.

The Evolution of Electrical Engineering in the Navy.

Summary.—The progress made in the employment of electrical apparatus in the navy from the earliest days is discussed, stress being laid on the difference in the conditions which exist on board ship compared with those on shore. The general lay out of the electrical equipment and the way in which it is maintained is then described, while the methods employed in lighting the ship and the directions in which the electric motor is employed on board a modern battleship are also considered.

The extent to which electricity and the electric drive are at the present time employed in the Navy has been prominently brought before the public by the recent discussion on the relative merits of electrical and hydraulic machinery for operating the main armament. On shore the average man nowadays looks upon electricity as one of the obvious things of life. The electric tram has ceased to astonish, while wireless telegrams have long ago lost their freshness. It, therefore, seems only natural to him that the same condition of things should exist in the Navy, that electric lighting and motors should be numbered among those things that are taken for granted, and used without any inquiry as to their why and wherefore. This is, however, scarcely the case, and for reasons which rest at bottom on the fundamental differences between a landsman and a sailor. A landsman, unless he be of a more than ordinarily enterprising nature, is willing to use the "benefits of civilisation" without attempting to find out their inner meaning, while, on the other hand, a sailor is the human embodiment of that mind which wants to know how everything works. He will, therefore, examine carefully the details of every piece of machinery which it is intended to use, adapt existing plant to his own requirements and generally strike out a line for himself.

These are, indeed, the reasons why the advantages of the electric drive for barbettes have not yet been recognised by the Navy as a whole, but it must not, therefore, be supposed that electrical engineering in the Navy has made no headway. This is far from being the case; in fact, for the very same reasons as those given above, paradoxical though it may seem, the progress of electric lighting and power in the Navy, especially during the last few years, has been extraordinarily rapid. At first much time was spent in adapting landsmen's plant to sea-going conditions, and to the discovery by experience of what arrangement worked best under gun-fire or in a heavy sea. But when these necessary preliminaries had been accomplished development in every direction was the immediate result.

Electricity was first used in the Navy for searchlight working. Small steam engines driving low-pressure (65-volt) dynamos were employed, each set supplying one light. It was, however, not long before the advantages of this system of illumination for wider purposes were recognised and arrangements made for lighting the cabins and other parts of the ship when the searchlights were not in use. This first step was followed by the introduction of electric lighting in a more extended form, and by degrees every ship was illuminated throughout by this means. The use of electricity for power purposes was not recognised then, or, indeed, till long after, such auxiliary machinery as there was at that time being driven by small and inefficient steam engines supplied through long lengths of piping in which no inconsiderable amount of steam condensed. The end of the first chapter of electrical work in the Navy, therefore, shows us the ship mainly electrically lighted throughout off low-voltage circuits. This stage, in fact, very fairly represents the state of things at the end of last century.

It soon became recognised that owing to the increasing size of the ships, and the consequent longer lengths of cable, the voltage then in use was too low for economical working, and 80 volts was therefore selected as the standard pressure. This pressure question again came up for consideration when the electric motor was first introduced in a small way, for it was naturally found cheaper to raise the voltage than to increase the copper. The voltage was primarily raised to 100, then to 105, while in the latest ships the pressure employed is 220 volts.

We may seem to have rather unnecessarily insisted on the voltage question, but here, again, the difference between land and sea-going conditions must be noted; and as this difference will continually crop up in what we have to say hereafter and is really not a little responsible for the present design of electrical apparatus in the Navy, it may be worth while to digress and to give a short sketch of the way in which electrical plant is operated on board one of his Majesty's ships.

At the present time all the electrical apparatus is in charge of the torpedo lieutenant, who is a commissioned officer. But the line of demarcation is drawn very sharply, and his responsibility begins at the dynamo and ends at the motor, irrespective of what machine is being driven, while he has no jurisdiction over the steam plant. This officer has under him a number of torpedo ratings, including one or more petty officers, who are, in turn, assisted by ordinary seamen, the actual number depending on the size of the ship. The officer and petty officers have all been through a course of instruction in electrical work on H.M.S. Vernon, and are thoroughly well acquainted with the plant employed in the Navy. But their outlook is necessarily narrow, and they view with a natural distrust anything they do not quite understand. In making this remark it must be understood that no reflection on the intelligence of naval electricians as a class is intended. But electrical engineering is a special subject, and even in civil life a man cannot expect to obtain a working knowledge of

every branch and phase of this very varied subject. Moreover, a civil electrical engineer has at least been trained in engineering from his youth up, while a torpedo lieutenant has only been able to take up electrical work as part of multifarious other duties. In the development that has been recently taking place, therefore, these officers and men have been hard put to it to keep up-to-date, and it is, therefore, scarcely surprising that there has been a certain amount of opposition to, or, perhaps it would be better to say "out-of-phaseness" with, the new *régime*. This has been especially so with regard to the question of voltage. In the early days, when electricity in the Navy was still in the experimental stage, and the best type of apparatus to use had not been determined, the equipment became easily damaged and shocks were sometimes obtained in unexpected places. Now, no one who has not experienced the effect can judge the magnitude of the shock that may be received even from an 80-volt circuit, when the recipient is standing on an iron deck that is in contact with the hull of a ship which is in turn immersed in sea water. The effect is literally electrifying. For this reason many naval electricians viewed with distrust the tendency to increase the voltage further. Simple arithmetical calculation will show that if the shock received from a 50-volt circuit be unpleasant, that from a 100-volt circuit is terrifying, while naval language on the subject of 220-volt circuits may be better imagined than expressed. In spite of this, however, it became an absolute necessity that the pressure should be raised, and, as this increase coincided with a better design of apparatus and a greater knowledge of electrical phenomena among the various ratings, the anticipated troubles have not been realised, and no more danger or unpleasantness is experienced with 220 than with 50 volts.

In this connection it may also be pointed out that the work of maintaining the electrical apparatus on board ship is hedged about with difficulties quite different from those met with on shore. In the first place there is the question of the *personnel*. We have said above that a certain number of men are told off to superintend the electric installations, but their number is by no means sufficient to do all the work, and they can at best only act somewhat in the position of charge hands. The labouring work, and even many of the more skilled operations, must be carried out by some of that large floating population which exists on board ship, by the sort of man who is one day painting, another day scouring, and another day replacing fuses—in fact, the original personification of the Jack of all Trades. This method of working obviously requires that all the apparatus should be sturdy and at the same time easy to understand, for to "take a brick and knock it" is the matlot's universal remedy for anything which will not work exactly and at once as it is wanted to. Further, when the motion of the ship is superimposed upon that of the plant, problems arise such as are never met with on shore. The design of a hoisting motor which will work at all angles to the horizontal requires some thinking out, while it must not be forgotten that such a motor may have to work and live in a cramped ammunition passage, where the ventilation is of the slightest. A ship, too, is not always in touch with the shore, so that large repairs cannot be made without difficulty, though each modern warship carries a fitters' shop. It is, moreover, highly essential that every part of the electrical apparatus should be capable of performing its work at a moment's notice, even after it has been standing idle for weeks in by no means ideal surroundings. It may be said that as a result of many years' experience these conditions are now fulfilled, and are reflected in the specifications on which the manufacturers have to tender. The Admiralty will take no electrical gear which, on the face of it, is not of the very best, and will not keep anything which has not shown itself capable of operating successfully both in the Indian Ocean and the Arctic Ocean, in the ammunition passages and on the boat deck. This is certainly as it should be, for the safety of the country depends on the good operation of this electrical apparatus at critical times.

We have seen that the electrical equipment of a modern battleship is made up of apparatus that can easily be looked after by an unskilled, though highly intelligent, *personnel*, that can be worked under a variety of very arduous conditions, and that is safe to handle in places where a low voltage shock is much more dangerous than on land. It may be as well now to come to particulars and to consider in some detail the various uses to which electricity is put in the Navy.

As regards the system of distribution, it was soon recognised that great precautions must be taken against damp, and in the older ships ordinary insulated cable was placed in impregnated wood casing, whose grooves were filled up with red lead. This method had certain obvious disadvantages—it was messy and the cables were not easy to get at. It has now been superseded by lead-covered wire, which is fastened direct to the bulkheads by brass clips. The wiring is not concealed, and, except at places where it is very liable to damage (for example, near bulkhead doors), it is not protected otherwise than by the lead covering. Where it passes through the deck special watertight stuffing boxes, rising some 8 in. from the deck, protect the cable, and in places where damage to the covering is likely to occur protection is afforded by covering the cable with sheet iron. No joints are made, but an ingenious system of sub-division in special distributing boxes is used. At the points where the wires enter the boxes an arrangement of soldered glands is employed to ensure watertightness, which is, of course, a very important point on board ship. The main circuits are metallic throughout, and leaving the main switchboard pass along one side of the ship returning along the other to the switchboard again, thus forming a complete ring. They are broken up on the way by a number of section boxes, from which sub-circuits are taken off to distributing boxes. In these latter boxes the circuit is further sub-divided and the lights supplied through suitable switches. This system, though it may appear unnecessarily complicated,

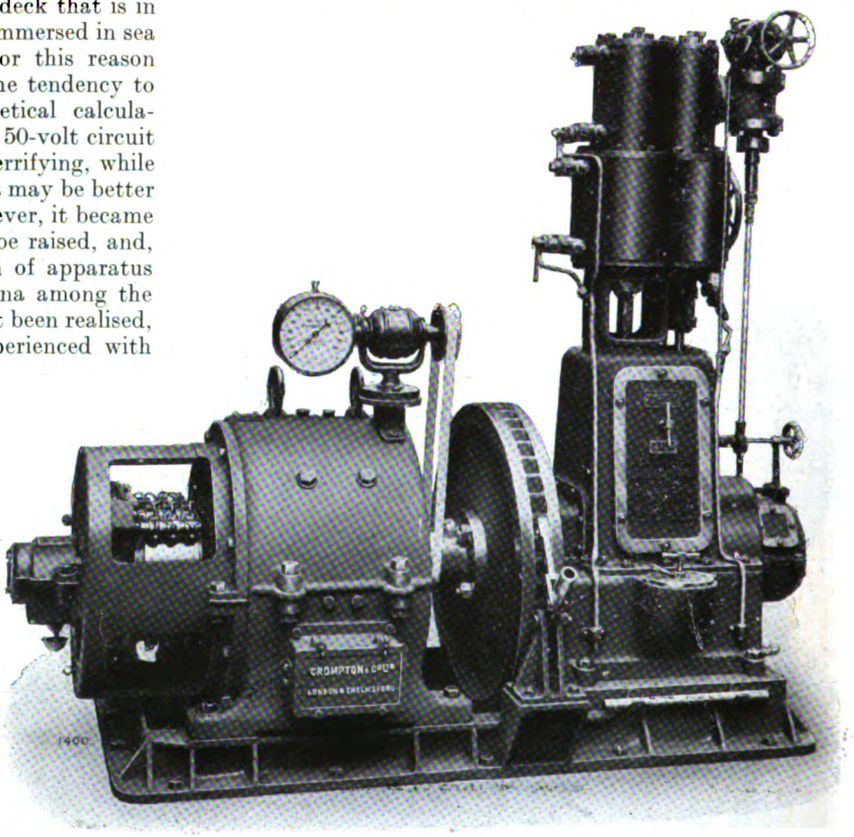

FIG. 1.—BELLISS-CROMPTON LIGHTING SET FOR MARINE WORK.

Digitized by Google

is really best able to fulfil naval conditions. The ring main system allows every lamp to be fed in two ways, and a further advantage is that a faulty circuit can be cut out with a minimum of disturbance to the rest of the installation. Ample fuse protection is provided, while circuit-breakers on the main switchboard and copper links in the section boxes allow the whole of the circuits to be most easily controlled. The arrangement described above applies more particularly to the lighting of the ship, though smaller motors are also grouped on one switchboard circuit and sub-controlled from section boxes. In the case of the larger motors, however, the rule is, one circuit one motor. This arrangement has its advantages, as will be gathered when it is mentioned that the current required by the after-capstan motor is sufficient fully to load one generating set. As regards the switchboards very little can be said; land criteria are followed as far as possible, though questions of space limit the distance at the back of the board and between the switches. Special arrangements are made for taking the arc, and the current-carrying parts are suitably protected to prevent any accidental contact when the ship is rolling.

The lighting of an average battleship is usually carried out on distinctly generous lines. At one time lamps whose filaments terminated in two copper loops were used. The supply leads were brought into a special holder and bent round into hooks on which these loops were hung, the necessary good contact being obtained by a circular spring placed over the base of the lamp. This arrangement was supposed to combat the evils due to vibration, but after much experiment it was found that more casualties resulted from attempting to fit the loops over the hooks than from vibratory causes; and the use of these lamps has, therefore, been abandoned, those with ordinary bayonet caps being now employed. In most parts of the ship the fittings used are remarkable for their simplicity. Bulkhead lamps are protected by a glass watertight shade which is, in turn, covered by wire network, and a similar arrangement is followed with regard to bracket lights. Magazines and other dangerous places are usually lighted from the outside. It may in general be said that whenever any artificial light is required at the present time electricity is used. Incandescent lamps are mostly employed, though a certain number of arc lamps are carried which can be used on special occasions. In this connection it may be mentioned that a number of spare ways are provided in some of the section boxes to which temporary wires can be attached when extra lighting is required for coaling or other special purposes.

Perhaps one of the most important problems which is exercising the minds of naval men at the present time is that of the disposition of searchlights. The subject is a very wide one, and as it is still in the melting pot it is impossible, and would, moreover, be inexpedient, to give any very definite information about what is being done. The problems of searchlight design are intimately bound up with those of protection. The methods taken for preventing our own ships from being seen, while at the same time turning the enemies' ships into as good a target as possible have both to be considered, and on the solution of these depends the strength and disposition of the searchlights used. The latter of these is perhaps the more important, and exhaustive experiments are at present being conducted to discover an arrangement which shall enable the gun-fire to be most efficiently directed.

Electrically, as much progress has been made with searchlights as with other plant used in the Navy. In the early days hand lamps with practically vertical carbons were used, of comparatively low candle-power and requiring a man to be always in attendance. These lamps have now been replaced by others of higher candle-power of the horizontal type and entirely automatic in action. In designing such a horizontal arc lamp cognisance had to be taken of the fact that the horizontal gear would not always be horizontal, due to the rolling of the ship. Special care had, therefore, to be taken to prevent any accidental contact of the parts and to arrange that the jarring of the ship should not cause the lamp to feed prematurely. Like other electrical problems in the Navy, this has been successfully overcome, and a lamp is now in use which, while automatic, is also unaffected by external influences.

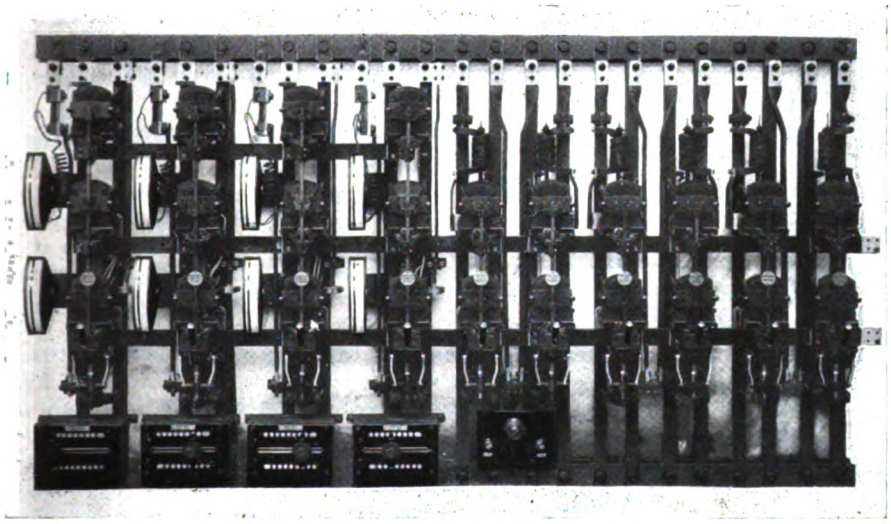

FIG. 2.—MARINE POWER AND LIGHTING SWITCHBOARD (CROMPTON & CO.)

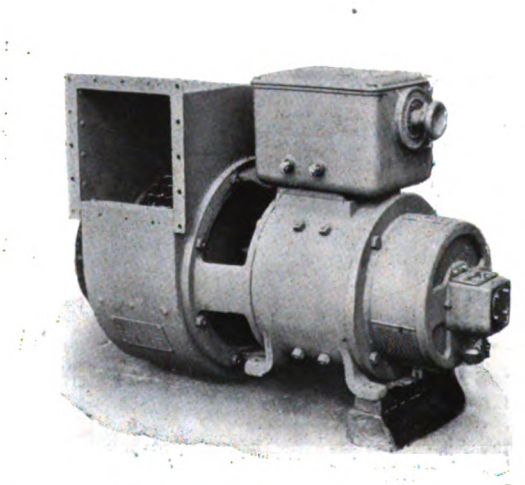

FIG. 3.—ORDNANCE FAN MOTOR (CROMPTON & CO.)

The adoption of the automatic lamp has also been the direct cause of the employment of another piece of electrical apparatus in connection with searchlight working. The movement of these lamps is now controlled from the bridge, small motors fixed in the base of the lamps being used to give the projectors the necessary elevating and traversing motions. Sufficient speed control is obtained by this means. In certain cases two projectors are fixed on a common base, so that the same motion can be imparted to both, while at the same time arrangements are made for moving each lamp independently.

Enough has been said to show that the use of electricity for lighting purposes on board ships of the Royal Navy is quite up-to-date, though the methods employed to attain the necessary end are rather different from those employed on land. The same remark applies equally well to power supply, in which connection the electric motor is finding an increasing application for the driving of the auxiliary machinery.

There can be no doubt that the low voltage employed militated for some time against the use of electric power to any great extent. And then, again, the authorities, following their practice of thoroughly examining a new thing before adopting it, were not at first quite sure of its advantages. The motor was first used in connection with the ventilation equipment, and even on the 80-volt ships, found an extended application

Digitized by Google

for driving fans. The fans employed vary very greatly in size, those used for stokehold ventilation reaching as much as 36 in. in diameter, while those for ordinary ventilation do not much exceed 6 in. There is no doubt that the compactness and unity of the electric motor were always points in its favour. Steam-driven fans could not be placed anywhere, while even under the best conditions the necessary supply piping took up much more room than the cables. It is also hardly necessary to point out that the heating up of the connecting steam pipes and the condensation in them made steam working uneconomical, as the distance on board ship may be fairly great, while the prevalence of steam pipes made an atmosphere which is often none too good absolutely unbearable.

The design of the fan sets used is principally noteworthy for its compactness. The motor is direct coupled to the fan and the controller is usually placed on the top of the motor, two or more speeds being provided according to circumstances. The motors are totally enclosed, and the whole of the sets undergo a searching test before acceptance. The atmosphere of a stokehold is not of the best for an electric motor.

Special arrangements are made in the case of the ventilation of magazines, the air being drawn in over ice made by a refrigerating plant, which is also motor-driven.

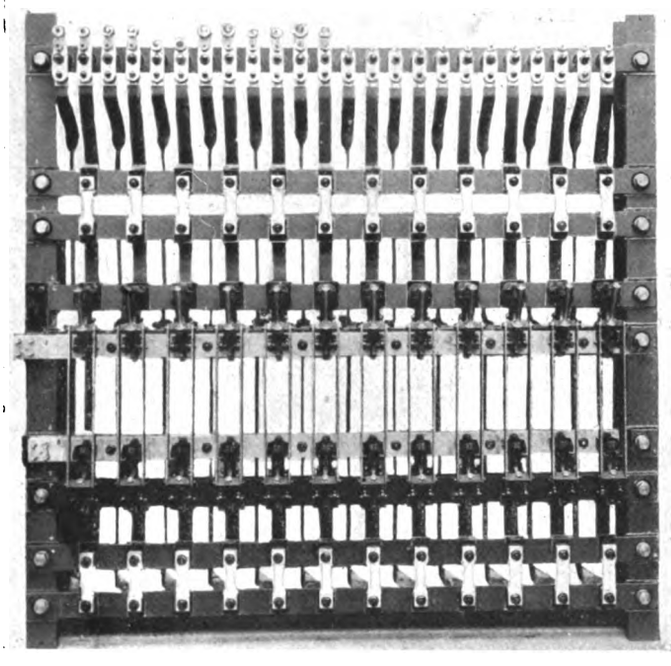

FIG. 4.—SWITCH PANEL (CROMPTON & CO.)

A large application of motors may be classed under the single word hoists. Electrically-driven hoists are, in fact, used in connection with the coaling, ash delivery, the supply of ammunition and the auxiliary boats, while the capstans mentioned above may also be placed under this heading. It would take too much space to go into the details of all this plant and would, moreover, serve no useful purpose, for as improvements are made the design alters and the description of one particular plant is not necessarily representative of a class. The necessity, however, for sturdiness in design mentioned above is exemplified in the following instance, which shows how the motor is applied to boat drill.

Each war vessel is provided with one or more steam-driven picket boats, which weigh five tons, and are used for conveying messages and passengers to the shore when the ship is lying in harbour. These boats are carried on special chocks on the boat deck and are hoisted and lowered by a motor. The movements are carried out in accordance with a drill, an officer on the bridge directing the man at the controller by means of flag signals. The motor's task would not be an easy one on land, for the load is both large and varying, but it is much more complicated at sea. If the sea is at all rough the directions of lift and the motor axis may be at constantly varying angles, while at the same time it is necessary that the motor should be brought to full speed practically at once, so that the boat may not be again touched by the waves after it has once left the surface of the sea. If this is not effected a chance wave may dash the boat against the side of the vessel, and at the same time, by taking the load off the motor, lead to double complications. It is, therefore, evident that the man at the controller must act instantly on the word of command and wholly forget that such operations as swinging the controller over to "full on" in one fell swoop are inherently bad for motors. Designers of boat-hoist motors are well advised when

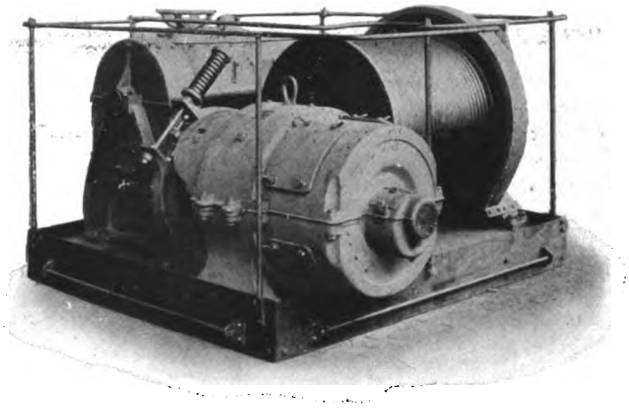

FIG. 5.—MARINE BOAT HOIST (CROMPTON & CO.).

they rate their motors and controllers generously and arrange for easily renewable contacts in the latter.

The motor is also finding an application for purely domestic purposes, for driving baking machinery, table fans and machine-tools. The problems to be met with in such cases are not different from those on shore, bearing in mind the variations mentioned above.

The one direction in which the electric motor has not yet fully established its claims is in the operation of the main armament. This is a matter which can scarcely be discussed here, but it may be said that success in this direction is merely a question of time and that the scare reports which have appeared recently on the unsuitability of the motor for this purpose emanate from circles who do *not* wish the motor to be a success—the wish being father to the thought. The problem is fairly clear; the motor has to move large masses very slowly and with great accuracy; given time and opportunity to experiment, the result can only be satisfactory.

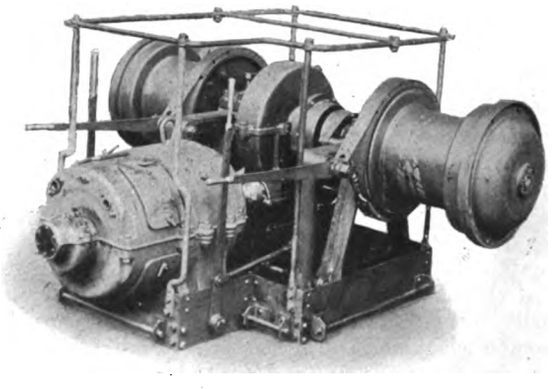

FIG. 6.—1-TON MARINE COAL HOIST (CROMPTON & CO.).

A part of the electrical equipment on board ship which is not the least interesting and certainly one of the most useful is that employed for signalling purposes. Both telephones and bells are largely used, code signals being employed in the former case. An ingenious combination of push and indicator

Digitized by Google

in one fitting allows the return signal to be easily given and received. Loud-speaking telephones are generally used for communicating orders from the bridge to the engine rooms, from the conning tower to the barbettes and from the engine room to the stokeholds. This arrangement allows orders to be clearly heard above the din, while the recipient need not be close to the instrument.

Both the telephone and bell circuits are. in modern ships, worked off dynamos which deliver current at 15 volts, though in the old days batteries were used. These dynamos are driven by small motors supplied from the power circuits. In this way much more reliable working is obtained than with batteries, while, owing to the fact that the circuits are operated from a main switchboard, greater ease of control is possible. The method of wiring and distribution in general follows that described above, though multi-core cable is extensively used, and in this way each interdependent circuit is kept under one lead casing. Separate bell circuits in connection with the officers' cabins and the various ship's offices are also installed.

There are two other applications of electricity on war ships regarding which much has been done just recently, but about which, quite rightly, no information is made available. These are fire-control and wireless telegraphy. The first of these is a well-thought-out system of electrical signalling, whereby orders can be conveyed to the various gun commanders from the conning tower and other control positions. As regards the second the development of wireless telegraphy in the Navy has been exceedingly rapid. Its benefits were much more speedily recognised than those of other electrical apparatus, and a special system has been devised to meet special needs. Details about its operation are necessarily not made public.

In the foregoing paragraphs we have endeavoured to give some idea of the present position of electrical engineering as applied to the Navy, and to make it clear that, in spite of difficulties and differences, the progress has been just as great on sea as on land, and that steady headway is now being made. There still remain, however, one or two problems to be solved. The question of barbette operation is one, and has already been referred to; marine propulsion is another. Practically all the auxiliary machinery on board ship is worked electrically, and assaults are now being made on the main engines as well. The problem is being considered, and the claims of the electric drive in this connection are not thought chimerical by those "in the know." So much is this the case that on every occasion when the subject is discussed steam engineers travel long journeys to point out its disadvantages. A scheme with no backing of reality would not be worth all this trouble.

At the beginning of the article we gave some account of how electrical affairs on board ships of war were administered and endeavoured to show how the native talent of naval officers had been successfully applied to problems not of the everyday type. Under this *regime* on board ship progress was made, but there was little control on land, and it was not until fully qualified civil electrical engineers were appointed that things electrical really began visibly to advance. The Admiralty electrical staff is now controlled by Mr. C. H. Wordingham, who is, of course, well known to our readers, assisted in each dockyard by civil engineers of wider electrical experience than that obtainable in the Navy. This leavening of good with better has had excellent results, and it may be safely said that from a technical point of view the evolution of electrical engineering in the Navy at the present time is nearing the maximum.

Marine Propulsion by Electric Motors.

BY HENRY A. MAVOR
(Of Messrs. Mavor & Coulson).

Summary.—The author here investigates a special case of marine propulsion where the existing method of driving is admittedly efficient and cheap, and shows that while the possibilites of economy are restricted there is still a strong case for electrical methods. The logs of two voyages are used to illustrate the argument that the "load factor" is likely to be an important element in the consideration of economical working at sea as it is on land.

It has only very recently been generally recognised that the problem of propelling ships by electricity may be considered as taking a place in practical politics. The demand for some new method of dealing with the power on war vessels when long runs have to be made at speeds much lower than the maximum has led to special study of the possibilities of economy by electric transmission of power between the main generator and the propeller. On war vessels of the cruiser class it is certain that economy is attainable by the use of means now available for the purpose, and it is only a question of gaining the confidence of naval engineers and authorities by demonstration of these means to justify them in taking up a new line of development in naval work.

The war cruiser of 20,000 H.P. is a heroic stride from the largest existing examples of naval propulsion by electricity, and it is, therefore, well that the electrical engineer should endeavour to bridge the distance by making intermediate applications.

Few cases are available where the possibilities of economy are so conspicuous as in the war cruiser, and in all cases including the cruiser the outsider who attempts to deal with the problems of naval propulsion finds himself at a grave disadvantage. This is natural. The electrical engineer is much younger than the marine engineer. His experience is more diffuse. His ways of thinking are foreign to the ordinary practician in engineering science. His pretension to exactitude of forecasting results is derided. His previsions are unsympathetically assimilated. These prejudices have to be broken down by the Miltonian method: "Add deeds to thy knowledge answerable."

The prevalence in engineering workshops of the long-resisted electric power arrangements has already done much to win a respectful hearing for the electrical engineer who knows his business. He will get all possible help from the scientific marine engineers, but in attacking the problem there are several serious difficulties affronting. Every branch of marine engineering has for many years been the subject of repeated practical experiment and careful observation of results, so that there is a vast mass of empirical knowledge on each special point, and an essential adaptation of means to ends and of ends to means, which render it fundamentally difficult to make any change.

At the same time there is plenty of encouragement to the electrical engineer to proceed in his attack on this region. He soon finds evidence of the presence of conditions which make for the use of his special means of utilising and combating the forces of Nature. The case here to be specially examined is typical of many, where on the surface the appearances are discouraging because of the successful work already accomplished by the marine engineer, but where there is still a good field for

the electrician. The character of the data of results of marine trials render them difficult of utilisation by the methods of the electrical engineer.

An example will make this clear. The records of trial trips are compared by the formula $\frac{\text{I.H.P.}}{D^{\frac{2}{3}}V^3}$, where I.H.P. is the horse-power developed in the engine cylinders, D is the displacement of the ship, and V the speed of the ship. The marine engineer says: "Here is a given ship; for what cost, weight of machinery and at what coal consumption will you give me the same I.H.P. to produce the same speed?" This seems to him a perfectly complete and fair way of stating the case; but to the electrical engineer such a question is absolutely meaningless, and it is not easy to put meaning into it. It is not safe to assume, although in most cases it is approximately true, that the propeller efficiency is the best attainable. It is rarely known what is the actual thrust imparted by the propeller to the ship.

If these two quantities were known, it still remains to be found what is the best attainable efficiency under the conditions of working to which the ship has to be subjected. This involves consideration of results of working the ship—in other words, the accumulation of a new group of data. All this looks very discouraging, but the application of the methods of the electrical engineer may be found to let daylight into the problem and may possibly be of service to the marine engineer.

The general principles upon which the proposal of electric Propulsion is based have been discussed by the present writer in Papers read in February, 1908, before the Institution of Engineers and Shipbuilders in Scotland, and in December, 1909, before the Institution of Civil Engineers. They need, therefore, be only summarily recapitulated here.

It is assumed—

That continuous currents are unsuitable for the purposes proposed because of the large size of the units, generators and motors, and because of the greater difficulty of dealing with large currents.

That, as it is now customary on land to generate all large currents as alternating currents, the same course should be followed at sea, and there does not seem to be any adequate reason for converting to continuous current.

That parallel working and synchronising are to be avoided, but that arrangements must be made for subdivision of the power equipment into convenient generating units, so that the load factor may be good.

Also that all switching arrangements for increasing, reducing or reversing power and speed must be of such a character as to be susceptible of instantaneous operation.

These requirements, it is claimed, have been met by the author's patented arrangements, which have reference to methods of combining the generator and motor elements.

The most important of the combinations are, first, that in which the secondary element of the generator or the primary element of the motor, which normally forms the stationary element, is rotated in a positive or negative direction by a concentrically arranged controlling motor, the connection being entirely magnetic and the currents used alternating. The use of this method gives a choice of periodicity or of speed of rotation, as the case may be, and, in the case of the motors, permits also of the independent application of two sources of power to one motor system, where they are added together without electrical connection.

In the second method, two or more generators are used at full power, each in connection with separate windings in the motor or motors, these windings being so proportioned that whatever may be their relative disposition they exercise no mutually inductive effect. These windings are arranged for successive connection to generators for change of speed.

It is to be noted that this is not simply a pole-changing arrangement. Although the motor is wound for two or more pole groups, these groups are at full power all in operation simultaneously.

For example, full power arrangement, three generators :—

—	Periods.	One motor having poles.	Synchronous speed per sec.
1. 4 pole, 6 revs. per sec....	12	24	1
2. 8 pole, 6 „ „ ...	24	48	1
3. 16 pole, 6 „ „ ...	48	96	1

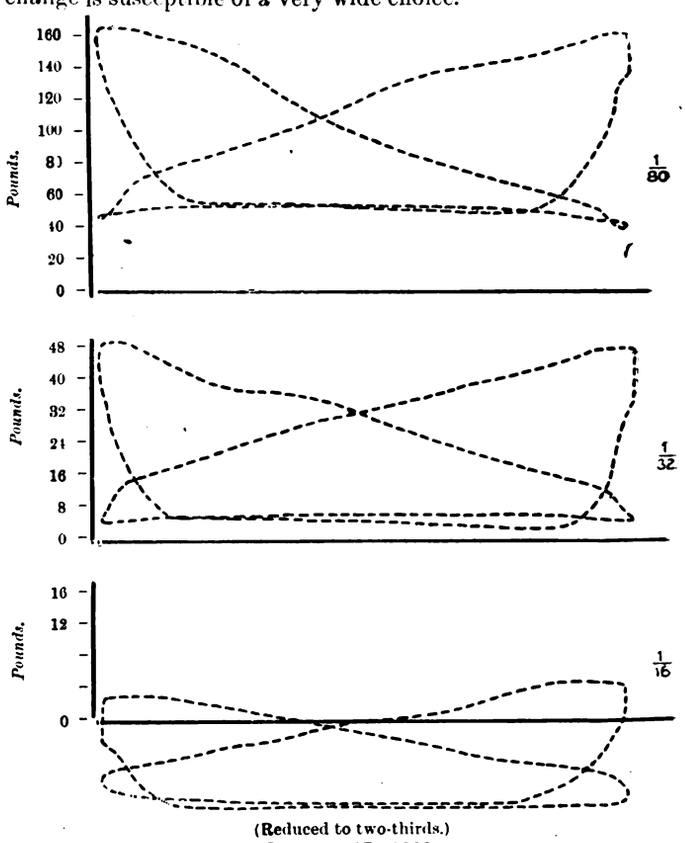
All three windings being laid in the same stator and at full power operating simultaneously on the same squirrel-cage rotor with the same resulting synchronous speed of 1 per second or 60 per minute.

The case supposed is one where the generators are driven by internal combustion engines.

Let now the arrangements be changed to two generators :—

—	Periods.	One motor having poles.	Synchronous speed per sec.
1. 4 pole 6 revs. per sec.....	12	48	0·5
2. 8 pole, 6 „ „	24	96	0·5

The speed is halved, the two generators being adjusted in size to give the required power. It will be seen that the speed change is susceptible of a very wide choice.



(Reduced to two-thirds.)

OCTOBER 13, 1909.

The discussion on the recent Paper at the Institution of Civil Engineers turned principally on the proposed application to cargo vessels, and it may be of special interest to readers of THE ELECTRICIAN to study a type of this class of vessel from the electrical engineer's point of view to ascertain what may be the possibilities of economy.

This example is chosen, not because it is a favourable case for the application of electrical transmission—it is not a conspicuously favourable one; but because, being a well-developed example of the best result of long experience in dealing with the special problems involved, it may be taken as typical of the best accomplishment of the existing methods, and limits the discussion to regions which are beyond that attainment.

In this cargo vessel of the "tramp" type, designed for a given draught and speed in fine weather, the coal economy is as good as can be attained by a combination of turbo-electric generator and motor, but the changes in working condition produced by changes in trim and weather appear to justify the use of the new method so as to get a better *load factor*.

Digitized by Google

The vessel is one of a fleet of many similar vessels carefully adapted to the work they have to do :—

Length between perpendiculars	370 ft.
Moulded breadth	52 ,,
,, depth	28 ,,
Draught loaded	23 ,,
Weight of hull	2,900 tons
,, ,, machinery	490 ,,
,, ,, cargo	7,194 ,,
Total displacement	10,584 ,,

Engine cylinders 25 in., 41 in. and 68 in. diameter × 48 in. stroke.
Boilers (three) 14 ft. × 11 in. natural draught, pressure 180 lb.
Total heating surfaces 5,868 sq. ft.
Total grate surfaces 165 sq. ft.
Bronze 4-blade propeller, 17 ft. 6 in. diameter, 17 ft. 9 in. pitch, surface 95 ft.

Comparison of three trials for which there are sets of indicator cards :—

	Nov. 1, 1907.	Oct. 13, 1909.	Dec. 10, 1909.
Displacement, in tons	5,041	10,000	4,500
Speed, in knots	12·4	9·8	9·8
Weight of coal per hour, estimated	3,450	...	...
,, ,, ,, measured	...	1,940	1,900
Indicated H.P.	2,038	1,265	1,096
Coal per I.H.P. hour	1·7	1·53	1·74
Estimated per shaft H.P. hour	1·9	1·7	1·93
Revolutions	72·5	56	62
Cut off on H.P. cylinder	0·608	0·45	0·47

Consumptions include steam steering, evaporator, and auxiliaries.

The first of the sets of indicator cards was taken on the "trial trip" of the vessel, the other two at sea on regular voyages.

The conditions of this trial are so abnormal that they are shown here simply for the purpose of general comparison. It would evidently be most uneconomical to drive this ship at 12·4 knots, and the engines are clearly not designed for this condition of working. They give a much better economy under the normal working conditions of a fully-loaded ship at a lower speed.

The other two records illustrate in a striking manner the incidence of "load factor" in ship propulsion.

Analysis of trial of October 13, 1909, for comparison with turbo-electric equipment :—

Assume value of coal at 13,000 B.Th.U. per lb.
Coal burned, 1,940 lb. per hour, as measured.
Total heat (assumed), $1,940 \times 13,000 = 25,250,000$ B.Th.U. per hour.

Boiler loss, assuming evaporation of 10 lb. water per lb. of coal from and at 212° — 25,250,000 — 1940 × 9,657	$6,650 \times 10^3$
∴ Boiler efficiency assumed = 0·73.	
Radiation and leakage	800×10^3
Cylinder condensation, &c.	$1,000 \times 10^3$
Driving auxiliaries and heating feed	$1,400 \times 10^3$
Steam in diagram— Cylinder volume $\frac{\pi(2\frac{1}{12})^2}{4} \times 4 = 13·6$ cubic ft. Cut off 0·45 = 6·1 cubic ft. Clearance 0·7 ∴ Total volume per stroke 6·8 cubic ft. at 0·304 lb. per cubic ft. mean weight at cut off × 1,100 B.Th.U. per lb. ; × 112 strokes per minute ; × 60 min.	$15,400 \times 10^3$
	$25,250 \times 10^3$

Heat efficiency of engine and auxiliaries in B.Th.U.
= 2,545 (being the heat equivalent of one horse-power-hour) × 1,265 H.P. ÷ $18,600 \times 10^3$ = 0·173.
Shaft H.P. (assumed) = 0·9 I.H.P.
∴ Heat efficiency of shaft H.P. = 0·155.

A single turbo-electric equipment for the same work would work out as follows :—

1,265 I.H.P. (assumed) = 1138·5 shaft H.P.

$$\frac{1138·5 \times 0·746}{0·93 \text{ motor efficiency}} = 910 \text{ kw.}$$

The guaranteed consumption of this plant would be 18·1 lb. steam per kilowatt-hour, including auxiliaries and all losses.

B.Th.U. per lb. steam = 1,100.

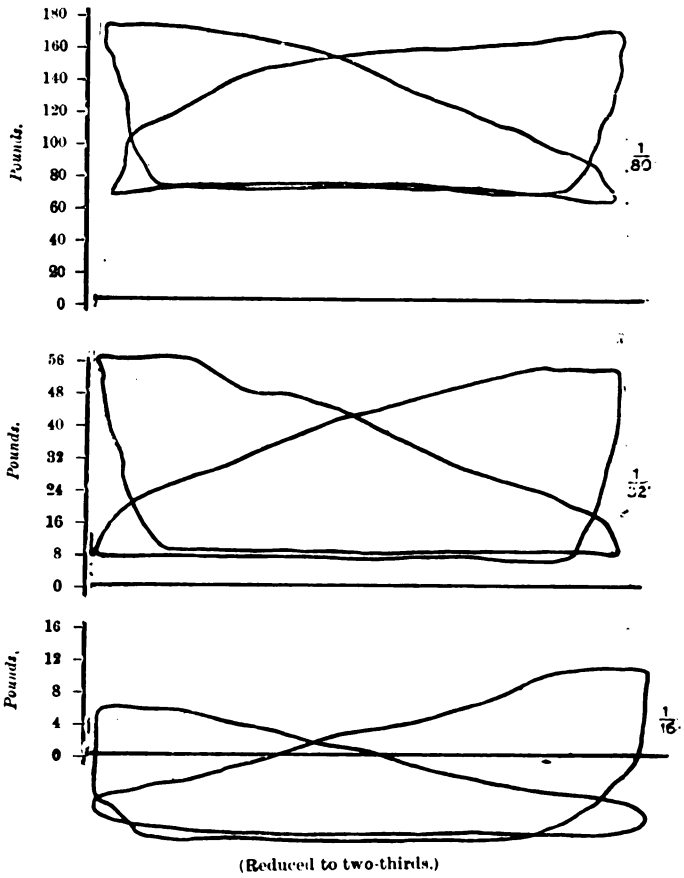
Kw.	Lb. per kw.	B.Th.U. per lb.	Total heat, units.
910	× 18·1	× 1,100	= 18,200,000

The economy of the turbo set would be slightly better than that of the normal equipment under the given conditions—

i.e., $\frac{1,138·5 \times 2,545 \text{ H.P.}}{18,200 \times 10^3} = 0·158$ of the total B.Th.U. delivered to the engine are accounted for by shaft H.P.

Evidently we have here in the existing reciprocating engine a highly efficient plant designed for its normal work, and not for the abnormal conditions of the trial trip in November, 1907, when the ship was run at a speed which would be very uneconomical in service. The cards taken on October 13, 1909, and on December 10, 1909, are typical, the first of the fully-loaded condition and the second of a half-loaded condition at normal speed.

The fully-loaded condition naturally gives the better result in respect of economy, and it has been seen that, making a reasonable assumption of mechanical efficiency, this result is so near to the economy of a turbo-generator motor combination at the same working pressures that no claim could probably be made on this score in favour of the substitution of the new method for the old. The daily log of the whole voyage



(Reduced to two-thirds.)
NOVEMBER 1, 1907.

of 22 days shows that the horse-power and revolutions were nearly constant over the whole period, and that the coal consumption varied little, although the speed of the ship varied from 7·55 to 9·9 knots average on the day's run by variation in resistance due to wind and sea causing a propeller slip varying from 0·007 negative to 0·215 positive.

The turbo-electric generator and motor equipment would be considerably lighter than the existing equipment, but it would cost more.

While accepting the position that on the voyage now in question the existing plant shows as good results in coal economy as a turbo-electric plant would show under the same conditions, we may digress for a moment to suggest that even here there is room for argument.

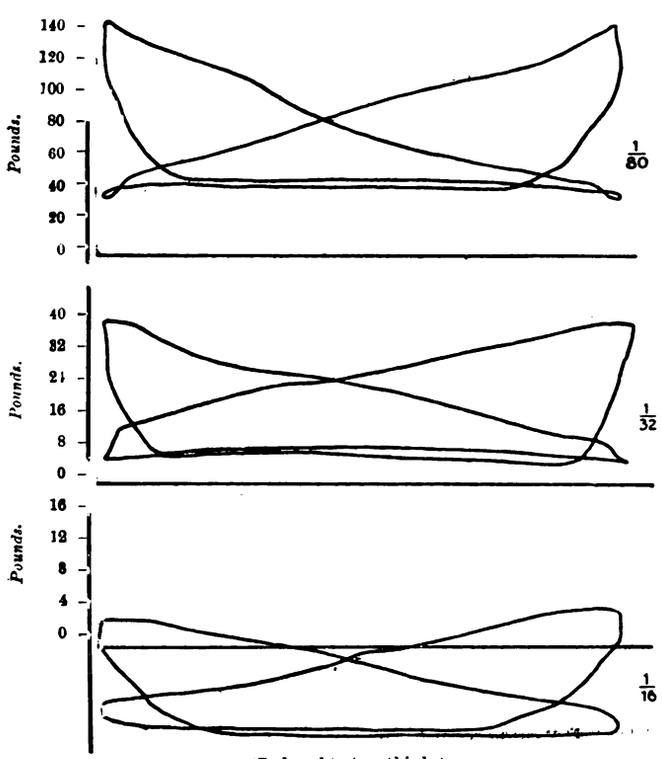
The great variation in resistance which is shown by the slip and speed variation is met by a change in speed of the ship till equilibrium is restored between pressure on propeller and piston. There is a great variation in propeller efficiency. The

Digitized by Google

fine weather efficiency of the propeller is high, as high as could reasonably be expected. To increase the diameter to improve the efficiency in heavy weather is probably impracticable. To use twin or triple screws is possibly out of the question with reciprocating engines on account of space, weight, cost and loss of cargo space by tunnels; but an electric equipment might change all this and provide a more favourable arrangement also for the condition now about to be examined.

Racing and consequent loss of power take place in bad weather, even when the ship is fully loaded. It is argued that the moment to moment changes in load would be more economically dealt with by a turbine running at constant speed than by the reciprocating engine, which must work under disadvantageous conditions with a fluctuating load.

The above diagram, taken on December 10th, is typical of a voyage of 20 days in a half-loaded condition. Here also the vessel was subjected to varying weather conditions, so that



(Reduced to two-thirds.)

DECEMBER 10, 1909, 10-11 A.M.

the speed of the ship varied from 8·2 knots to 10·05 knots average on the day's run. The propeller slip varied from 0·04 to 0·391. The average revolutions per minute on the day's run is constant at 60, with the exception of three days at 50, 58, 59. The average horse-power is again nearly constant, and is 86 per cent. of the horse-power required to run the ship when fully loaded. But this horse-power is developed under much less advantageous circumstances. The cut-off is later, the steam is checked at the throttle, the mean pressure is much lower, the clearance losses are relatively greater, the propeller, being only partly immersed, races badly, wasting steam and losing way. All these losses would be obviated by the use of an electric arrangement in which the power on the ship would be divided into two units of the relative power shown on these two trips—*i.e.*, they should be in the ratio of the two values of the horse-power—viz., 1,096 and 1,265—1,096 = 169. Assumed brake horse-power = 980 and 152.

It is probable that the mechanical efficiency of the engine is much less at the lower power, and that 980 is too high an estimate of the shaft horse-power for 1,096 I.H.P., but this difference may be neglected in the line of argument here adopted; the principle is fully illustrated as it stands.

The motor would have two windings, and the general arrangement would be :—

—	Motor.					Generator.				
	B.H.P.	Poles.	Synchronous Revs. per sec.	Synchronous Revs. per min.	Actual revs. per min.	Kw.	Poles.	Revs. per sec.	Periods.	Revs. per min.
1st winding...	980	104	0·96	58	56	785	2	50	50	3,000
2nd winding.	152	94	0·96	58	56	123	2	45·83	45·83	2,750
1st winding...	152	104	1·06	64	62	123	2	53·6	53·6	3.220
2nd winding.	980	94	1·06	64	62	785	2	50	50	3,000

The two motor windings would be of equal area, and the larger unit would be run at or near its full speed and best economy, and on this voyage only one unit (the larger) would be required. It would run at full load all the time, and its coal consumption would be per hour :

$$\frac{\text{Kw.} \times \text{lb. B.Th.U. per lb.}}{\text{9,657 B.Th.U. per lb. coal}} = \frac{785 \times 18 \times 1{,}100}{9{,}657} = 1{,}620 \text{ lb. coal per hour}$$

as compared with 1,900 lb. used by the existing plant. A very handsome saving. When the whole plant is required at either speed of revolution the coal consumption would be increased by

$$\frac{\text{Kw.} \times 125 \times 22 \times 1{,}100}{9{,}657} = 310 \text{ lb. per hour,}$$

making the total coal, as has been said, about the same as at present.

The question for the owner is to evaluate the debits and credits on account of the electric proposition on the basis of the existing propeller arrangements in the first instance :—

Dr.	*Cr.*
Novelty and breach of conservative policy.	Saving in weight.
Extra cost.	,, space.
	,, coal on light voyages.
	Use of the small plant for cargo working.

In the case which we have discussed the owner has decided that in the meantime the balance is to the debit.

The matter does not rest here, but we may leave the argument for the moment at this stage, with the claim to have shown that the margin in favour of the existing arrangements has already been narrowed down close to the disappearing point, and that there is here a wide field for the electrician.

In the case chosen it is disputed that economy is possible and admitted that it is much to be desired. Probably the internal combustion engine may come to our aid in dealing with comparatively small powers such as here discussed, and enable us to proceed with confidence to the larger sizes, where it is much easier, owing to the higher efficiency of the larger sizes of steam turbo-generators, to show a decided advantage in coal economy.

One very great difficulty with which the electrical engineer has to deal may be emphasised in conclusion.

Marine engineers are accustomed to work on much wider guesses or estimates of the quantities with which they deal than are electrical engineers. They do not know that an electrical engineer's guarantee of efficiency can be checked to a degree of accuracy unapproached in any other branch of engineering, and they make claims of economy which the electrical engineer cannot dispute, but which it is impossible to verify. It is, therefore, necessary to show for the electric proposal a much larger margin of saving than is actually required to justify its adoption.

There are cases in which the margins are sufficient to satisfy the most exacting critic. These are the cases where large powers are used with wide and prolonged variations in the load factor.

In the smaller powers the method has to be demonstrated in more difficult and less remunerative cases, such as have been here discussed.

The discussion at the Institution of Naval Architects' spring meeting has added considerably to the knowledge of

Digitized by Google

this subject by the experiments made by the Hon. C. A. Parsons in transmission by gearing. The present writer agrees with Mr. Parsons and the other speakers in the discussion referred to that the question of electrical propulsion must be compared with the older methods under conditions which are rigorously similar. There must be no mixing up of gains by the use of superheat, the assumption of propeller efficiencies obtainable only under conditions which are precluded by the working limitations of the ship, or other methods which are not at present available at sea. To do so is to obscure the issue and to alienate the sympathies of people who are expert in the business of marine propulsion.

A System of Turbo-Electric Propulsion of Ships

BY H. C. LEAKE.

Summary.—In the system here described ordinary three-phase generators and squirrel-cage motors are used, and speed variation of the propelling motors is obtained by varying the speed of the turbo-generators. To enable the motors to be reversed, braking drums are employed, mounted on the turbine shafts, and which may be described as a species of turbine designed to absorb power instead of to produce it.

General interest is being felt at the present time in the question of methods of improving the efficiency of turbine propulsion of ships. Among the methods that have been proposed the turbo-electric system ranks high on account of the advantages it seems to offer, and it may fairly be anticipated that sooner or later the enterprise of the shipping section of the community, both naval and mercantile, which collectively has so successfully led the way to advances in the past, will result in the carrying out of a trial on an adequate scale to verify the possibilities of utilising electricity for this purpose.

An account of a new system of turbo-electric propulsion covered by patents held by the British Westinghouse Electric & Mfg. Co. (Ltd.) may, therefore, be of interest at the present moment, as this system, the invention of Mr. J. N. Bailey, has not yet been described in any publication.

Before going into details, we may briefly refer to the leading points by which the relative merits or demerits of any electrical system for ship propulsion must be judged, without attempting to recapitulate those well-known advantages which can be claimed in common for all systems of electrical propulsion.

First and foremost is placed economy, and by this is meant economy in the most comprehensive sense, bringing in many points outside the province of the electrical power specialist. Steam per horse-power delivered to the propeller is only one element, as the question of the possible efficiency of propellers at various speeds of revolution also becomes of equal importance. The commercial or other value of any saving or excess of weight and space realised in engine room, boiler room, and coal capacity must necessarily enter into the complete problem. Lastly, the question of probable expenditure on running stores and attendance, maintenance and repair, is one that the marine engineer may be trusted not to lose sight of.

Together with economy, reliability and simplicity of the mechanical and electrical system necessarily take a high place. The chief engineer's share of the responsibility for the safety of a ship, whether naval or mercantile, is so onerous that he cannot be expected to welcome an aggregation of machinery in which, from want of familiarity, he does not feel confident of being able to locate any breakdown that may occur in working. It is, therefore, desirable that an electrical system should be as simple as possible in both mechanical and electrical respects, so that its action may be easily comprehended, which will tend not only to reduce the chances of a breakdown, but also will render it easier to deal with any trouble that does arise. As experience under seagoing conditions grows, the embodiment of complications might be found justifiable if superior advantages could be thereby obtained, as has been the case in the development of other applications of electricity that will occur to the reader; but, in the initial stages at any rate, a simple system is the one most likely to present a practical compromise between conflicting requirements.

Much has been written at various times about propelling ships by electrical transmission, but very little information has been vouchsafed by the advocates of various systems as to how they propose to stop the ship when in full motion. Yet in all matters of land transportation, such as railway trains, tramcars and motor cars, the attainment of high speeds under practical everyday running conditions has been due quite as much to the excellence of the braking devices as to the sufficiency of the propelling agent. Ships with propellers direct-driven by reciprocating engines, or by turbines with astern sections, possess a natural braking power, so that this point has not demanded special consideration; but with electrical transmission the situation is somewhat modified, and when engineers propound ingenious means of applying electricity to impart motion to a ship they should not omit to explain how they arrange to stop the ship quickly as well. In brief, rapidity of stopping and going astern are most important points to be provided for.

With any electrical system full power can be utilised when actually travelling astern.

There must be afforded a certain power of regulation of speed, but the particular requirements in this respect vary with different classes of ships, and each case requires detailed consideration on its merits. In the case of war ships, the exigencies of "station keeping" render it necessary to have a very fine adjustment of speed over a large range, whereas for mercantile ships the conditions in this respect are not so onerous, and it seems likely that with experience it would be found that regulation facilities essentially superior to such as are obtained in the case of electrically-driven trains were not as a rule indispensable. The question of speed regulation is, however, bound up with that of economy at reduced speeds, as to which the necessary requirements vary much in different cases.

An electrically-propelled ship of fair size must naturally in the first instance be considered somewhat an experiment, just as the early turbine-driven ships were experiments in their day. It is, therefore, very desirable that the essential elements of the propelling machinery of such a ship—viz., turbines, generators, cables, and motors—should be in as many respects as possible of standard and well-tried construction which has been well proved by everyday successful operation under the less onerous conditions of land service. In this respect we shall merely be following the precedent set by marine turbine development, as it was not until the genius of Mr. Parsons had perfected the steam turbine for land uses that serious attention was paid to its application to marine propulsion.

In the case of large ships with not less than two turbo-generators and two motors, it is worth considering to what extent any electrical system is well adapted to afford opportunities of minimising the effect of breakdown in any one part by means of temporary expedients, either designedly provided for as a precautionary measure or improvised when the occasion arises. In this way any increased liability to a breakdown due to the multiplication of parts in the chain of transmission of power, as compared with direct-driven propellers, may well be offset by the increased opportunities which electrical methods afford

to make temporary arrangements to cope with such emergencies.

Coming now to describe the British Westinghouse Co.'s system, the motors direct coupled to the propellers would be of the alternating-current three-phase squirrel-cage type. Such motors are, as is well known, the most simple and robust type existing, and require neither commutator, slip-rings, brushes, regulating switches, nor resistances. In Fig. 1, which shows diagrammatically an arrangement for a ship with four propellers, the motors are indicated by A, A, A, A.

There would be two turbo-generators, B, B, each driving two motors, and consisting of a high-speed steam turbine fitted with a special device to be described later, and coupled to an alternating-current three-phase generator. The exciting current would be furnished by separate small generators, which would also supply current for other auxiliary purposes.

Each motor would be supplied with current by an independent line of three-phase cable, C, C, C, C. Each line of cable would pass through a simple reversing and isolating switch, D, D, D, D, which would be enclosed in iron cases located in accessible positions in or near the engine room. The voltage of transmission could be selected at any value desired within reasonable limits, and as the whole of the parts of the machinery which carry current at this voltage are stationary,

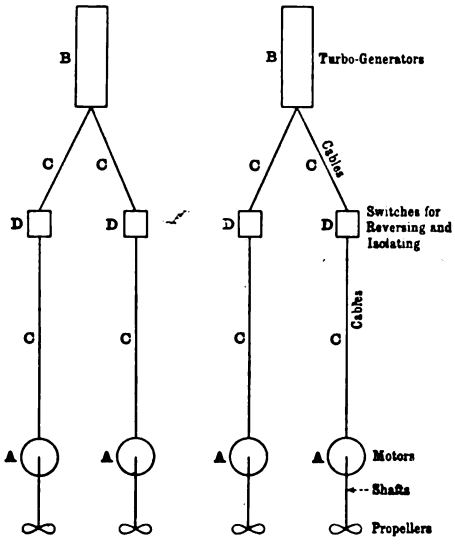

FIG. 1.—GENERAL SCHEME.

enclosed, and inaccessible to those running the machinery, there would be no difficulty in going to very considerably higher voltages than those at present used for power purposes on ships.

Each of the turbines would be fitted with a very powerful brake, one form of which would consist of some rows of stationary and moving blades so shaped and set that on turning steam into this part of the turbine sufficient resistance would be offered to the rotation of the drum to reduce its speed quickly. The amount of steam which could be utilised in the brake would be the same as would be available for driving the turbine in the ordinary way, and as questions of economy would not arise, it would be possible to obtain a very powerful braking effort with very little addition to the size and weight of the ordinary turbine.

With the exception of the exciting arrangements for the alternators, which being simple and of ordinary character have not been indicated, Fig. 1 comprehends the whole of the parts of this system which are vital to its effectiveness in respect to generation and application of the power; and, in view of the nature of the elements described, the claim for simplicity may thus far be well sustained. Any complication in construction or arrangement would be confined to the controlling apparatus, the functions of which will be explained later, but any derangement or breakdown in this controlling apparatus would not incapacitate the ship in any degree from propelling itself.

We may now consider the use of this system. The generators having been excited, in order to start the ship from rest all that is needed is to open the steam valves of the turbines, when the motors will start up with the generators, running almost in synchronism with them until full speed is reached. Any speed of ship may be obtained by suitably regulating the speed of the turbines in the same way as in present turbine ships. If when running at a considerable speed it is desired to stop the propellers and reverse their rotation, this, as is well known, cannot be done by simply throwing over the reversing switches D, D, D, D. To take this course without any supplementary measures would bring about, through electrical action, an excessive strain on both generators and motors.

It may be done if adjustable rotor resistances are provided for the motors, but the great advantages offered by the squirrel-cage motor must then be sacrificed, and, moreover, rotor resistances for such large powers as are likely to be required present considerable practical difficulties which are best avoided on ship-board.

A method that has been proposed in some electrical schemes with the object of enabling the squirrel-cage motor to be retained consists in breaking the generator field circuit in order to make it possible to throw over the reversing switch and then to build up the field again by gradual steps. This cannot be considered a satisfactory method, because, in order to develop any reasonable amount of torque, the current in the generator and motor would be excessive, so that, as the permissible current fixes a limit to the torque that can be exerted, this method is not adapted for stopping and starting a ship with the degree of promptness that is desirable.

By the British Westinghouse Company's system in the form described above the difficulty is overcome in the following way: Assuming that it is desired to change from "full speed ahead" to "full speed astern," steam is shut off from the working portion of the turbine and admitted into the steam brake. The motion of the ship in the ahead direction operating through the propellers drives the motors as generators, transmitting power back to the generator, and thereby driving the turbine. This power is absorbed in the steam brake, where any amount of surplus energy can be dissipated in a form which offers no difficulty in its disposal. The speed of the ship is thereby effectively and rapidly checked, until finally the speed of the generator and motors has fallen to a point at which the frequency is sufficiently low to enable the reversing switch to be operated without causing excessive current. Steam is then immediately shut off from the brake and simultaneously admitted into the working portion of the turbine. At the reducad frequency which the voltage applied to the reversed motors now has the motors are able to develop full load torque with normal current without the need of rotor resistances, and consequently a powerful effort can be exerted to check completely the motion of the ship and start it in the reverse direction. The turbine gradually runs up to full speed, when ultimately the ship travels astern with the same full power available as for propulsion ahead.

In order to illustrate the general nature of these operations, a diagram is given in Fig. 2, which shows graphically the general manner in which the various speeds, torques, &c., vary during the process of carrying out the order "full ahead" to "full astern." These curves are intended to be typical only, and are not to scale.

The various operations described—namely, shut off main steam, open brake steam, throw reversing switch, shut off brake steam, open main steam—are brought about automatically in the correct sequence and period by an electrically-operated controlling mechanism which is brought into action by any movement of the regulating hand wheel on the starting platform or elsewhere. It would unduly extend this article to describe the details of this controlling mechanism by which the steam valves and reversing switch are automatically operated, which mechanism may take various forms; but it is important to notice that the control of the ship, though impaired, would not be destroyed by breakdown in any part of this automatic controller, since the various operations which it brings about could

in case of necessity be effected entirely by hand equally well, though not so expeditiously. The controlling mechanism is the only part of the equipment in which there is any degree of intricacy, but the ship would in no way be disabled even by some derangement of this part.

A similar cycle of operations, except for reversing, would be followed when reducing from any speed to a lower one, the object then being to cause the speed of the ship to respond to the control hand wheel in the shortest possible time; but, of course, this cycle would not be brought into action when increasing speed.

The system lends itself excellently to direct control from the bridge in the event of this being required.

From the particulars that have been given it will be seen that thus far the British Westinghouse Company's system embodies the desirable points, that great economy can be attained at full speed, that full power can be utilised for checking the speed of the ship and for travelling astern, and that any speed from zero to full speed can be obtained; but in respect to relative steam economy at reduced speeds, compared with that at full speed, there cannot be much advantage over direct-coupled turbine ships, as in each case reduced speed of ship entails a reduced speed of turbine, though the absolute economy in the former system may perhaps sometimes be superior.

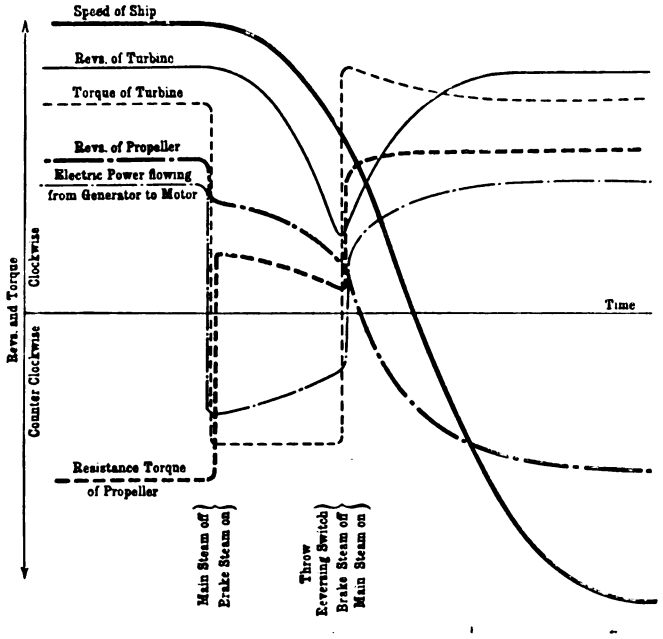

FIG. 2.—FULL AHEAD TO FULL ASTERN. (TYPICAL CURVES.)

Propeller assumed left-handed. Going ahead requires clockwise rotation of propeller (looking aft), and resistance torque is counter clockwise.

It depends very much on the special circumstances of the individual case whether the attainment at reduced speeds of better economy than this system gives is of importance; but, if necessary, such as is the case with warships, there are various ways of arranging for this. Any method which is now applied to improve the economy of direct-coupled turbines at reduced speeds is also applicable to the electrically-driven ship, and, in addition, there is a gain in that the whole of the propellers may be grouped on one turbine where more than one is fitted, and the other turbines be shut down entirely. Or by varying the number of poles of the motors by means of pole-changing switches, the speed of the turbine may be kept up to the full at a reduced speed of the ship.

In some cases it may be found justifiable to instal a single small turbo-generator to drive all the propellers when cruising at reduced speed for a considerable period, this machine being arranged so that its full speed frequency corresponds to the reduced speed of the motors. It is easy to embody change-over switches (which are only operated when there is no voltage) with the other switches in the switch boxes D, D, D, D. As the power required for propulsion varies roughly as the cube of the speed of a ship, the relative weight and space of such an auxiliary cruising turbo-generator in conjunction with its superior steam economy may not represent an excessive increase, and it affords substantial additional advantages in the way of stand-by resources, thus reducing still further the chance of complete disablement of the ship due to a breakdown.

As regards the question of the actual steam consumption for propulsion at full speed, it is not proposed to take up this point on the present occasion, as figures published from several sources have shown sufficiently encouraging possibilities for turbo-electric systems in general. In respect to the influence which the propeller has on the question, there seems to be at present no general consensus of opinion among naval architects and marine engineers. It is sufficient to note that, as the Westinghouse electrical transmission system utilises the most simple type of generator and the most simple type of motor, the losses are likely to be certainly no greater than those in any other electrical system.

Already electrical machines of the ordinary form have been built in sufficiently large powers to suit almost any ship yet constructed. The arrangements described render it possible to adopt an electrical system of propulsion in which machines of standard construction such as are in everyday successful operation for land service can be employed in the most simple manner possible. The predominating feature of this system from a practical point of view thus lies in its mechanical and electrical simplicity, which is in a high degree conducive to maximum reliability of operation, so important in the case of propulsion of ships.

In conclusion, the combination of advantages special to the British Westinghouse Company's system may be summarised as follows:—

(*a*) The electrical generators and motors are in every respect similar to machines of standard and well-tried construction, and the turbines are also standard, except for the addition of the steam brake, which offers no mechanical difficulties.

(*b*) Slip-rings, starting switches and resistances in connection with the motors are completely eliminated.

(*c*) Means are provided for rapidly checking the speed, which should materially assist the handling and manœuvring, of the ship.

(*b*) During starting, stopping, and reversing, practically full torque may be exerted on the propeller shaft without exceeding normal current in generator and motors.

Acknowledgments are due to Mr. J. S. Peck and Mr. J. N. Bailey for advice and assistance in the preparation of this account.

Motors for Marine Work.

On sea as on land the motors of the Lancashire Dynamo & Motor Co. are well known for their excellent qualities. They are now being daily employed on R.M.S. "Mauretania" in connection with the ventilation of the enigne rooms and cabins. Eight fans are in use, each being driven by a 25 H.P. motor. The same company have lately supplied a number of motors to various battleships, where they are engaged on the following duties: Workshop driving, turbine turning and lifting, refrigerating and pumping. On one of the recent ships, too, the necessary electrical energy is generated by dynamos of the Lancashire Dynamo & Motor Co.'s make. These machines are of the open type with a commutator end-bearing only. They are coupled direct on a combination bed to the flywheel of a vertical four-cylinder oil engine. The capacity of each set is 450 amperes, and they deliver current at 210 to 240 volts when running at 400 revs. per min.

The Lancashire Dynamo & Motor Co.'s machines are found to be quite reliable when stowed away in the ammunition passages or on one of those cramped landings which are come across on the descent to the stokehold. The stoker, in spite of the atmosphere in which he works, is able to come up now and then for a breath of fresh air; but even this boon is denied the motor, which must always welter in the heat.

Electrical Marine Propulsion on the "Paragon" System.

BY WILLIAM P. DURTNALL.

Summary.—After a brief reference to the conditions to be observed in marine propulsion, the author considers two cases in detail in which the effect is estimated of replacing the usual steam drive by the "Paragon" electric system. The first is the ss. "Lusitania," in which, although the saving in weight of plant is not material, the saving in coal and wages is shown to be considerable. The second case is that of a "tramp" steamer of 500 H.P., in process of conversion.

The great commercial success of electrical power transmission on shore is now well established, and many thousands of electric motors are to-day employed in innumerable ways in many and various industries. While, however, these applications have made progress, electrical marine propulsion has also been receiving attention, and has more or less quietly asserted itself as an art and a very promising industry. Thanks to the great modern improvements in steam turbines and internal combustion engines, the time has now arrived when electrical propulsion for vessels of large power and size may be discussed as a commercial subject.

In the author's opinion, owing to the vast power to be handled, the electrical propulsion of large ships will only be possible by the adoption of a polyphase current system.

The great advance made quite recently in the design and construction of turbo-alternators and induction motors of large output has made the successful application of electricity in this large and important field appear commercially feasible, and several schemes are now in hand for the propulsion of large passenger and cargo steamers; in fact, the present year may witness some remarkable advances in marine electrical engineering.

All designers of steamships are at the present time striving to obtain the highest efficiency—that is to say, the greatest amount of thrust from the propeller—for every horse-power delivered to the propeller shaft, and at the same time to reduce the steam or fuel consumption per horse-power-hour so delivered. Every little increase in efficiency in this direction means that the steaming radius for a given amount of fuel is increased.

It has been proved beyond doubt that the propeller that gives the most efficient results is one which runs at a low speed and with blades of large area, and is the result of many years' practical experience on thousands of vessels both at home and abroad.

As regards prime movers, the advent of the steam turbine has overcome many of the disadvantages of the reciprocating engine. The best efficiency of a steam turbine is generally obtained when the linear velocity of the rotating blades is equal to one-half that of the steam velocity impinging on these blades, and as this figure is very high, in order to apply the steam turbine to marine propulsion, it has been necessary to raise the speed of the propeller at the expense of propulsive efficiency, so as to reduce the possible steam consumption per shaft horse-power developed; but the result is not comparable as regards steam and fuel economy per horse-power developed with that of the high-speed land turbine under equal steam and other conditions. In order still further to raise the turbine to more efficient operation it has been suggested by the author and others that mechanical gearing should be used.

If by some means the steam turbine can be run at a high speed, not only is the weight and cost of the turbine per horse-power reduced considerably, but the amount of steam used per horse-power-hour delivered is also considerably reduced. If the first cost and running costs are sufficiently reduced, although there may be some losses in transmitting the power produced by the high-speed turbine to a slow-speed propeller, on the whole there will be a net gain. Further, there may be a great reduction in weight and cost of decreased boiler, steam-pipe, condenser and coal bunker capacity required when using the higher speed turbine.

It will not be out of place here to refer as briefly as possible to some of the conditions that have to be met with when designing the propelling machinery for steam vessels of all kinds. It must be remembered that as far as we engineers are concerned we must "save coal." It is obvious then that the turbine must be run at its one and most efficient speed, and that a high speed, in which the use of superheated steam is possible. But it is important that provision should be made for running a ship economically at the lower speeds which are often required. This applies particularly to "tramp steamers." It is also very important to provide a quick and powerful reverse, so that the vessel is under complete control. Further, it should be borne in mind, that although the power falls rapidly with the vessel speed, the torque required on reversing is higher than that when running at top speed, so that suitable provision must be made. For this it is essential to reduce the weight of the working parts as much as possible. Means must also be provided that in the event of the propeller leaving the water, as is often the case in rough weather when the vessel is pitching or rolling, racing of the propellers cannot be excessive.

The importance of a suitably low propeller speed is shown by the opinion of Dr. Robert Caird, who is one of the most eminent authorities on naval architecture and marine engineering, that had the "Lusitania" been fitted with propellers suitably designed to give the same vessel speed, and if they were driven at 80 revs. per min. instead of 188 revs. per min., as at present, the propulsive efficiency would have been raised to 60 per cent., instead of the 48·4 per cent. as now at about 25 knots. Consequently, instead of the 65,500 shaft horse-power now required, only 52,830 shaft horse-power would have been necessary.

Electrical engineers labour under a very great difficulty in making extremely accurate estimates in connection with electrical propulsion, but certain published data are available on which estimates may be based. Certain engineers in this country have in the past stated that there is no room for electrical power in the propulsion of vessels of such large size as the "Lusitania." From this view the author would respectfully differ, and he will endeavour to make out a case for an electrically-driven boat of similar lines and speed, in which the "Paragon" system can be employed if necessary. We will first consider what the existing boat is doing, and to do so we cannot do better than take the points that are given by Mr. Thomas Bell, the engineer of the firm who built the vessel, in a most interesting Paper that he read before the Institution of Naval Architects a short time ago, and which dealt with the steam trials of that important and record breaking Atlantic liner. From these it appears that the total steam consumption for all purposes with a horse-power of 68,850 was 14·94 lb. per shaft horse-power-hour. The corresponding coal consumption was 1·46 lb., the speed being 25·4 knots, and the estimated total coal consumption for a voyage of 3,100 nautical miles at this speed is 5,490 tons. The actual coal consumption was very close to this figure.

Digitized by Google

The steam consumption works out as follows :—

Main turbines	851,500 lb.	= 13·1 lb.	per S.H.P.-hour.
Auxiliary machinery	114,000 lb.	= 1·75 lb.	„ „
Evaporating plant and heating, &c.	32,500 lb.	= 0·5 lb.	„ „
Total	998,000 lb.	= 15·35 lb.	„ „

The average amount of coal burnt per hour for all purposes was 43½ tons, and the water evaporated per lb. of coal burnt was 10·2 lb., the feed temperature being 196°F. It will thus be seen that under service conditions the total average power of the four propeller shafts of the "Lusitania" was found to be approximately 65,000 H.P., and the propulsive efficiency being 48 per cent., shows that the effective horse-power was 31,200.

Turning now to the electrical scheme, we will first consider the power required on the propellers for the same vessel speed, using four propellers as at present. The author, after careful investigation, has come to the conclusion that if induction motors are to be of such a diameter that they shall go into the narrow after-lines of this boat, a speed of 140 revs. per min. for the top vessel speed would have to be adopted. Thus, the saving in power by reason of the extra propeller efficiency, due to the adoption of lower propeller speeds, would not apply to a very great extent, but would apply as between the efficiency at 188 revs. per min. and that which can be obtained at 140 revs. per min. The ascertained propulsive efficiency being increased from 48 to 52 per cent., we shall therefore require for a thrust equal to 31,200 H.P., 60,000 shaft horse-power at 140 revs. per min.

To provide the above power at 140 revs. per min., we can assume two 7,500 B.H.P. induction motors, mounted on each of the four shafts. Each motor will have, say, 42 poles, and an efficiency of about 97 per cent., so that, leaving out of account the small losses that would, of course, take place between the generators and the motors in conductors and control gear, we shall require a total of, say, 47,000 kw. of electrical power for propulsion purposes. Motors of this power and speed can be designed with the above efficiency and a weight not exceeding 50 lb. per B.H.P., so that each motor will weigh, say, 167·4 tons, and the eight motors would have a total weight of say, 1,340 tons.

To supply them with the necessary current at full speed and load, as given above, the installation of six 11,000 B.H.P. steam turbines will meet the case. Fig. 1 shows the layout proposed, with four of the above turbines (B, C, D, E) running at 600 revs. per min., and the other two (A, F) running at 1,050 revs. per min. G and J are six-pole non-synchronous three-phase generators, H and I are four-pole transformer-generators, K and L are four-pole synchronous generators, and mounted on the same shaft are M and N two-pole transformer-generators; and O and P are the small series wound exciters, which, owing to the arrangement, act for the whole combination, by exciting the revolving magnets of K and L, through slip-rings Q and R. The output from K can be put into the revolving primary member of M, by means of the slip-rings S, and the output from L can be put into the like member of N through the slip-rings V.

The estimated efficiencies of K and L can be put at 96 per cent., also 96 per cent. for H and I, and for the higher speed short-circuited generators G and J 97 per cent., and for M and N 94 per cent., which are reasonable figures for the estimated steam consumption required for the various powers. Working at 180 lb. pressure above atmosphere, and with the steam superheated to a total temperature of 600°F., and with a vacuum of 28·5 in. (easily obtained in the Atlantic), it can be safely stated that at full load the above turbines, if constructed on the mixed principle, will require a total not exceeding 9 lb. of steam per brake horse-power-hour; so when the above plant is working at full speed and load (as at top vessel speed) the boiler capacity need only be sufficient to supply 594,000 lb. of superheated steam per hour.

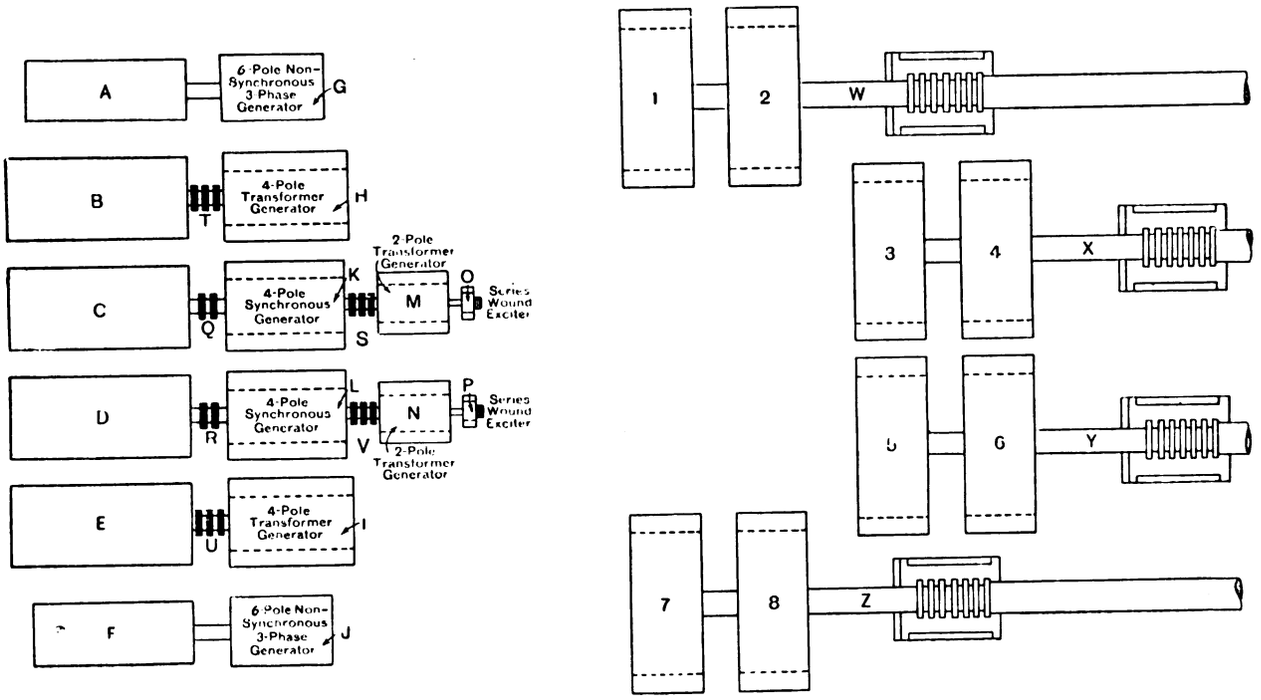

FIG. 1.—PROPOSED LAYOUT FOR VESSEL OF 60,000 SHAFT-HORSE-POWER AT 139 R.P.M.

The weight of the turbines, generators, transformer-generators, non-synchronous generators, exciters, steam and exhaust piping and condensers is estimated at 90 lb. per kilowatt of output, so that for the 47,000 kw. required for propulsion the total weight of the engine-room equipment will be 1,880 tons.

The remote control system would be adopted with motor operated switchgear, and all connections would be arranged to be made or broken under no-voltage conditions, and in such manner that either port or starboard motors may be changed in speed or direction of rotation. The weight of the whole of this control gear can be put at 25 tons.

So far we have dealt with the generation and transmission of the electrical power from the steam valves of the high-speed turbines to the half couplings of the motors driving the propellers. As regards the weight of the boiler installation, a very good estimate can be made from the report of the committee on naval boilers, in which the Cunard liner "Saxonia" was taken, and the details show that the weight of the boiler-room equipment was 1,000 tons, and that the total output from

Digitized by Google

the cylindrical boilers installed was equal to 132,600 lb. of saturated steam per hour, or 132·6 lb. of steam per hour per total ton weight of the boiler-room installation. This weight included the following items: Water in boilers at working level, Howden forced draught fittings and funnelage, auxiliary machinery in boiler room, including evaporators, &c., and steam pipes, platforms, &c. A figure of 180 lb. per ton weight per hour may be safely taken for modern cylindrical boilers.

Thus the total weight of the boiler-room equipment for the electrically-driven boat for propulsion only will be, for the 594,000 lb. of steam required, 3,300 tons, to which must be added, say, 75 tons for superheaters, bringing the weight of the boiler-room plant up to 3,375 tons. We have then the total weight of the boilers, and the propelling machinery for the electrically-driven boat as follows :—

Boilers, &c.	3,375	tons.
Turbines, generators, &c.	1,880	,,
Controllers, &c	25	,,
Conductors, say	10	,,
Motors	1,340	,,
Total weight of propulsion machinery	6,630	,,

As laid out in Fig. 1 the working would be as follows for five speeds of the propellers in either the "ahead" or the "astern" direction.

First Speed.—Start up either turbine set C or D, say, C. This will run at 600 revs. per min. By means of the control gear send current from the small exciter O, through the slip-rings Q, to the windings of the revolving four-pole magnet of the synchronous generator K. The three-phase current from the stationary armature of this machine passes to the slip-rings S of the primary member of the transformer generator M, the direction of the current being such that the magnetic flux revolves in the opposite direction to that in which the generator is being driven by the turbine C. The three-phase current for the motors will then have a frequency of 600 cycles per minute, and the motors having 42 poles will run at a synchronous speed of 28·6 revs. per min.

Second Speed.—The second speed is obtained as follows :—First short-circuit the field of the small exciter by means of the control gear; then couple the motors direct to the armature of the generator K, the transformer generator meanwhile running idle. The current will then have a frequency of 1,200 cycles per minute, with the result that the motors will run at a synchronous speed of 57·2 revs. per min.

Third Speed.—It should be here noted that the power for the two lowest speeds of such a vessel would easily be provided by one turbine. To obtain the third speed, turbine D is now started up and runs at 600 revs. per min., together with the synchronous generator L, transformer generator N, and exciter P. Motors 1, 2, 3 and 4 are then supplied by turbo set C, and motors 5, 6, 7 and 8 by the set D. By opening the links across the fields of the exciters O and P, the exciting current flows through the slip-rings Q and R to the revolving magnet windings of K and L. The output of the armatures of the last-mentioned machines passes to the primary windings of M and N, the direction of the current being such that in both cases the magnetic flux revolves in the same direction as the turbines C and D. It will be seen that the frequency of the current supplied to the motors will then be 1,800 cycles per minute, and the motors will run at a synchronous speed of 84·8 revs. per min.

Fourth Speed.—Under no-voltage conditions, as mentioned above, the connections are changed as follows, and more power being required, turbines B and E are started up (running at 600 revs. per min.) The current from the armatures of K and L, instead of going to the slip-rings S and V, is in this case sent to the slip-rings T and U, which are connected to the windings of the primary members of H and I, the direction of the current being such that the flux revolves in the same direction as the turbines B and E. The frequency of the current obtained from the stator secondary members of H and I will be 2,400 cycles per minute, and the motors will run at a synchronous speed of 114·2 revs. per min. It may be mentioned that the power required for propulsion will at this speed be easily met by the four turbines B, C, D and E, and also that in each case the voltage goes up with the frequency so as to meet the extra demand for power.

Fifth Speed.—This (in the present layout of the "Paragon" system) the highest speed is obtained in the following manner. The current, instead of flowing from the armature of the generators K and L to the slip-rings T and U, as in the previous speed, passes again into the slip-rings S and V; and the current from the secondary members of M and N is then taken to the slip-rings T and U, so that the magnetic flux in the mechanically driven members of H and I revolves in the same direction as the turbines B and E. The frequency of the current thereby obtained is raised to 3,000 cycles per minute, so that the motors will run at a synchronous speed of 143 revs. per min. (with, say, 3 per cent. slip, giving actually 139 revs. per min.). At this speed more power will be required for propulsion, and this extra power can be obtained by starting up turbines A and F. These latter drive short-circuited squirrel-cage rotor generators, wound for six poles. By coupling the stator windings to the mains by means of a simple chopper type switch, the 3,000-cycle current revolves in the same direction as that in which the rotor is being driven, say, 1,050 revs. per min., by turbines A and F. The power is thus boosted up (as it may be termed) to meet the 60,000 B.H.P., say, that is required from the motors at top speed.

Under the above working conditions, and when the ship has a clear run for a long distance, the necessary adjustment can be made on either of the turbines C or D; and when a synchronous speed is obtained, the port and starboard sets of generator H and I can be paralleled.

With a vessel such as the "Lusitania" rolling 10 deg., say, the propellers are very unequally immersed. Ordinarily the speed varies between the port and the starboard side, with the result that with heavy rolling there is a great waste of fuel by reason of the unequal torque on the two sets of engines or turbines. It will be obvious, however, that in the electrically-driven boat, when running with the generators in parallel, the power will fluctuate between the port and starboard motors, and that the generating plant will run at a constant load whatever the difference in immersion of the two propellers. Also that when a propeller is lightly immersed its motor (owing to the frequency being fixed by the generators) will not race, and the motor driving the more deeply immersed propeller will, for like reasons, not slow down (at least not more than, say, 2 per cent.). Further, owing to the extra pressure per square inch of blade surface, better grip will be obtained on the water by the more deeply immersed propeller and more thrust will consequently be given, especially if calculated per ton of coal used per vessel mile under such conditions. This result could not be so effectually obtained in practice by any other means than electric propulsion and squirrel cage motors, the running characteristics of the latter being almost identical with those of the screw propeller.

I hope to be in a position in the near future to publish some interesting figures as to the actual performances of vessels so fitted.

It will also be interesting to make a comparison of the relative weights and steam consumptions. Here, again, we shall deal with the matter up to the half-coupling of the existing turbines, which run at 186 revs. per min. at top vessel speed. As regards the engine room weight of the "Lusitania," the weights of the six rotors are given as follow :—

	Weight in tons.	No.
High-pressure rotor, each	80	2
Low ,, ,, ,,	120	2
Reversing turbine rotor ,,	60	2

It is reasonable to suppose that the weight of the bed and case of the above turbines will be at least twice that of their rotors in each instance; that being so, we have the following weights :—

Low-speed marine turbines,	at least 1,570	tons.
Condensers (two)	,, 300	,,
Circulating water	,, 100	,,
Steam pipe connections, including exhaust, with the necessary change-over valves, &c.	200	,,
Total estimated weight of engine room equipment	2,170	,,

Now, as regards the weight of the existing boiler room plant so far as that portion required for propulsion only is concerned, it is stated that under service conditions the total steam used by the main turbines is 851,500 lb. per hour. Assuming that 180 lb. of saturated steam can be produced per total ton of boiler room equipment weight, the weight of the existing boilers will be 4,730 tons, which includes the weight of all mountings and steam pipes to the stop valves of the turbines and the funnelage and necessary auxiliary machinery, feed pumps, &c. Thus we have the estimated weight of the propulsion machinery and apparatus for the existing boat as follows :—

Engine room machinery	2,360 tons
Boiler room plant	4,730 ,,
Total estimated weight of plant for propulsion	7,090 ,,

Compared with the electrically-driven boat the weights are as follows :—

Direct drive at propeller speed of 186 r.p.m.	7,090 tons
"Paragon" electric drive at propeller speed of 140 r.p.m.	6,630 ,,
Saving in total weight by electrical equipment	*460 ,,

Although this is the saving in dead weight of the plant, it is not to be assumed that it nearly represents the total saving in weight, since difference in fuel has still to be taken into account. The evaporation on the "Lusitania" being at the rate of approximately 10 lb. of water per pound of coal, it follows that the existing boat requires at top speed no less than 38 tons of coal per hour, or 882 tons per day. Assuming five days' steaming, this becomes 4,410 tons of coal for the run from, say, Liverpool to New York.

In the electrically-driven boat the steam consumption per hour is only 594,000 lb., so that, taking the same evaporative efficiency for the boilers, we have a coal consumption of only, say, 26·5 tons per hour, or 636 tons per day. For the five days' steaming, therefore, the boat will only require 3,180 tons for propulsion, which is a reduction in fuel for the same vessel speed of 28 per cent. This means a saving in weight to be carried of 1,230 tons. Quite apart from the weight so saved there is a liberation of space to the extent of 54,120 cubic. ft., which is no longer required in coal bunkers and is available for other purposes. Similarly, there is a saving of 50 furnaces on the 192 now used, and only three funnels instead of four would be necessary. Again, there would be a saving of, say, 50 stokers and 31 trimmers. It is obvious that for every man saved in the stokehold there is corresponding keep, and accommodation is set free for a larger number of steerage passengers.

As to first cost in types of vessels that the author has recently investigated, it has been found that with the "Paragon" system the cost is approximately the same as for reciprocating triple-expansion engines running at 80 revs. per min. of the equivalent power, and that the weight of the plant is about the same; but in larger powers the first cost of the propelling machinery and steam plant for a given effective horse-power is less than with either direct-coupled turbines or reciprocating engines.

Assuming five days' steaming and 30 trips per year, the cash saving is therefore as follows :—

Coal, 1,230 tons per trip, or 36,900 tons per year at 13s. per ton	£23,935	0	0
50 stokers at 28s. per week	3,640	0	0
31 trimmers at 22s. per week	1,773	4	0
Net saving per boat per annum	£29,398	4	0

Apart from the above commercial saving in cash in operation, it must not be forgotten that valuable time is saved in not having to bunker the coal saved.

So much for the largest type of vessel afloat. We will now investigate electrical driving for the smaller class of vessel, such as the usual "tramp," as these boats are in the great majority and a very large business will be done in the near future in their conversion, as well as the equipment of new vessels.

Fig. 2 shows a side view of a vessel of the above description that the author has now in hand for equipment on this system, and which he anticipates will be the forerunner of a large number of similar vessels, owing to the great reduction in fuel that will be demonstrated and to the extra steaming radius that will be shown.

Fig. 3 shows a side view and plan of the turbine and generating plant proposed for this vessel. This is as follows :— A is the steam inlet for the supply to the high-pressure turbine of De Laval type shown at B, C the connection between the high-pressure and the low-pressure De Laval type turbine D.

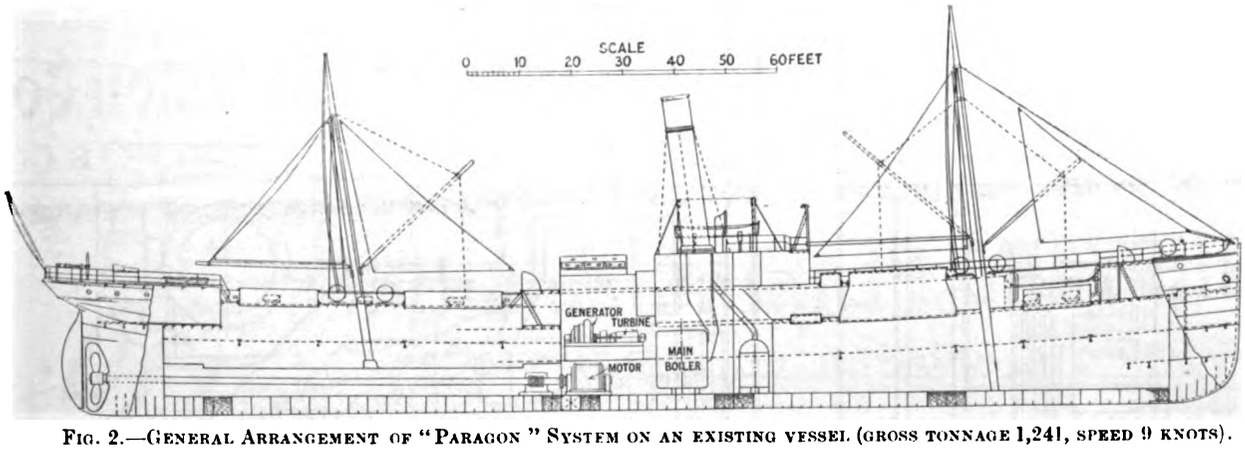

FIG. 2.—GENERAL ARRANGEMENT OF "PARAGON" SYSTEM ON AN EXISTING VESSEL (GROSS TONNAGE 1,241, SPEED 9 KNOTS).

The exhaust is shown at E; this is coupled to the condenser, which will be directly under the turbines; F is the speed regulator; G G are two pinions that reduce the turbine speed from 2,400 to 500 revs. per min., H the main driving gear wheel which, by means of the coupling O, drives the revolving magnet I of the four-pole three-phase alternator. On the same shaft, and also driven mechanically by the turbine H, is the primary member of the transformer-generator K. This is a two-pole machine, with its secondary member L stationary. The exciting current, which will be taken from the electric lighting installation on board at 80 volts pressure, will be led to the slip-rings M; and for the lowest and the highest of the three speeds provided in this instance for the motor and the propeller (a single-screw vessel is in question) the output from the alternator will pass into the slip-rings N, and the operation will be as follows :—

First Speed.—The turbine will be started up and run at 2,400 revs. per min. For both the high and low-pressure turbines the revolving magnet and the primary members therefore run at 500 revs. per min., say, in a clock-wise direction. The motor that is to be used will be wound for 34 poles, and will be of the simple squirrel-cage type. For the first speed the terminals of the alternator will be coupled to the slip-rings N, and the current sent in such a direction that the magnetic flux revolves in the opposite direction to that in which the revolving member is being driven. Three-phase

* 6·4 per cent.

Digitized by Google

current at a frequency of 500 cycles per minute will therefore be drawn from the secondary member L, and being supplied to the 34-pole motor, the latter will have a synchronous speed of 29·4 revs. per min.

Second Speed.—This speed is obtained by taking the current from the armature of the alternator J direct to the motor. This will then run at a speed of 58·8 revs. per min., the transformer-generator running idle.

Third Speed.—This speed will be obtained by again sending the output from the alternator to the slip-rings N, but the current will flow in such a direction that the magnetic flux revolves in the same direction as the mechanical rotation. The transformer also acts as a generator, raising the frequency to 1,500 cycles per minute, and the motor will run at a synchronous speed of 88·2 revs. per min.

The actual speeds for the propeller will, of course, be slightly less by reason of the slip at the motor when under work, and they will probably be 29, 57·5 and 86 revs. per min. respectively.

The existing engines are triple expansion, running at 78 revs. per min. and indicating about 500 H.P. With the same amount of steam the turbine will give, with saturated steam at 150 lb. pressure and with 28 in. vacuum, 630 B.H.P. at the main wheel; the over-all electrical power transmission efficiency will be, at top speed and load, 82·5 per cent., so that the motor will give to the propeller shaft 520 brake or shaft H.P. at, say, 86 revs. per min., the increase in shaft speed giving a higher vessel speed. The present reciprocating engines have an efficiency of about 83 per cent., so that they give only about 415 shaft H.P. to the propeller; the extra power required for the higher propeller speed, when the vessel is on top speed, will be easily met by the extra 105 shaft H.P. given by the electric motor at 86 revs. per min. with the same boiler power.

The weight of the engines and the condensers that are to be replaced by the electrical installation is about 37 tons, and the weight of the turbines, generator-transformer, condenser and motor is about 36 tons; but with the extra girders that will be put in to carry the turbines it can be safely said that the weight of the machinery will be approximately the same as the reciprocating engines.

Before being dismantled the vessel will be docked and cleaned, the engines and boilers put in condition, and then the vessel will undergo a thorough trial under various draught conditions and speeds, in which the towing resistance, I.H.P., steam and coal consumption, and the actual cost of carrying a certain freight per vessel-mile will be observed. Exactly the same test will be made when the electrical plant is on board, and the results will be recorded in these columns at a later date.

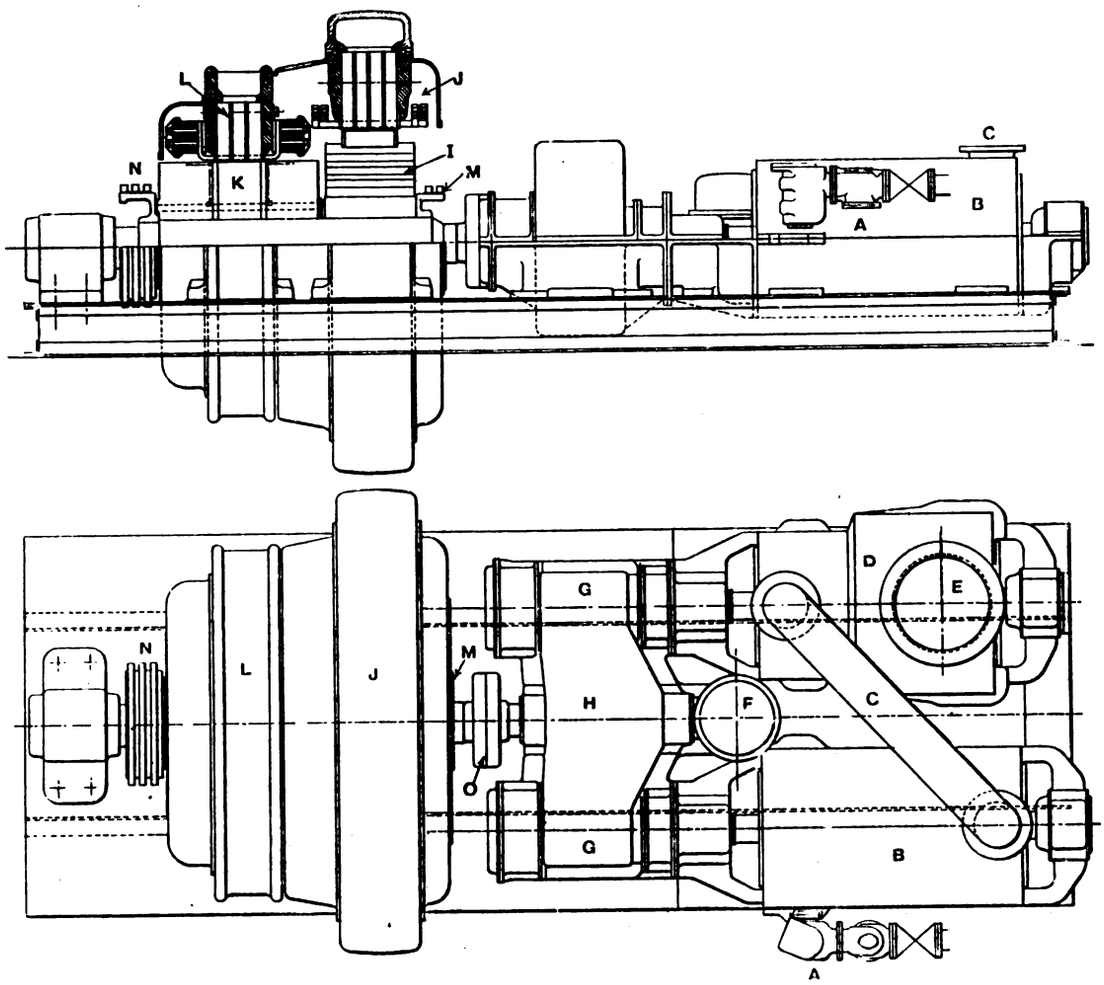

FIG. 3.—"PARAGON" GENERATING PLANT FOR VESSEL ILLUSTRATED IN FIG. 2. (Scale 1:40.)

The author hopes that the above remarks will awaken some further interest in what he believes to be the future field for the progressive electrical engineer with the co-operation of his marine colleague.

The author's thanks are due to those friends who have already considered the possibilities of this system of electrical power generation and transmission for marine propulsion, and also to Messrs. Willans & Robinson and other important turbine makers who have so kindly given the writer the particulars for the turbine section of this article and drawings. Signs are not wanting that the shipping industry is about to undergo a great change in view of the lively foreign competition that is now taking place; and based on the information that is available to the author in various directions, his views are that immediately the electrically-driven vessel is put to a real test the shipowner will be driven to adopt electric driving on the lines here laid down.

Electro-Mechanical Propulsion with Diesel Engines.

BY ENGR.-LIEUT. W. P. SILLINCE, R.N.

Summary.—After giving figures as to the economy of the Diesel oil engine and features of construction, the author describes its use at the present time in boats, and finally outlines the Mirrlees system of electro-mechanical propulsion. In this system, generators direct coupled to Mirrlees-Diesel engines are used. For speeds between full speed and half speed a combined friction and positive clutch couples together the engine and propeller shafts. For speeds below half speed the shafts are disconnected and motors are used.

The Diesel oil engine is well known and is firmly established in land installations; it has also been frequently applied to marine purposes, both for generating electricity in ships and also for the propulsion of surface and submarine boats and of cargo-carrying vessels.

In the British Navy alone every battleship and armoured cruiser commissioned since the time of the "Dreadnought" has been fitted with at least one, and most of them with two, Diesel oil engines, whose duty has been to generate electricity for auxiliary purposes. These engines were manufactured by Mirrlees, Bickerton & Day (Ltd.), of Hazel Grove, near Stockport.

The installation of these engines has resulted in great economies in fuel and attendance. For example, one of these Diesel oil engines was found to use ½ ton of residual fuel oil (the same as used for boiler firing) per day of 24 hours, whilst to do the same work with a steam plant of exactly the same capacity 7 tons of Welsh coal were required—that is, 14 times the weight of fuel. Assuming coal to cost £1 per ton and fuel oil £2. 5s. per ton, the Diesel engine thus effected a saving of £5. 17s. 6d. per day, or about 84 per cent of the fuel bill. The guaranteed fuel consumption given by the makers of these engines is 0·55 lb. per brake horse-power per hour at full load, 0·57 lb. at three-quarter and 0·65 lb. at half load, and the actual results on service are usually 10 per cent. less than these figures.

Further, to attend to the steam plant, each watch consists of four men—two to trim coal, stoke and tend the boiler, one to tend the engine-room auxiliaries (such as condensing plant and feed pumps) and one for the steam dynamo—and, as there are four watches per day, 16 men are required. When the Diesel oil engine is in use 12 of these men are available for other duties, since the Diesel oil engine requires only one attendant. It might here be mentioned that when two Diesel oil engines are installed in the same dynamo room one attendant looks after both.

As touching on the question of continuous running and reliability, these engines have on several occasions run for 30 days and nights without a stop.

The engines are vertical and direct acting, each having four cylinders and capable of developing 160 B.H.P. (200 I.H.P.) continuously, when running at 400 revs. per min. They are direct coupled to 105 kw. generators, and run in parallel with either

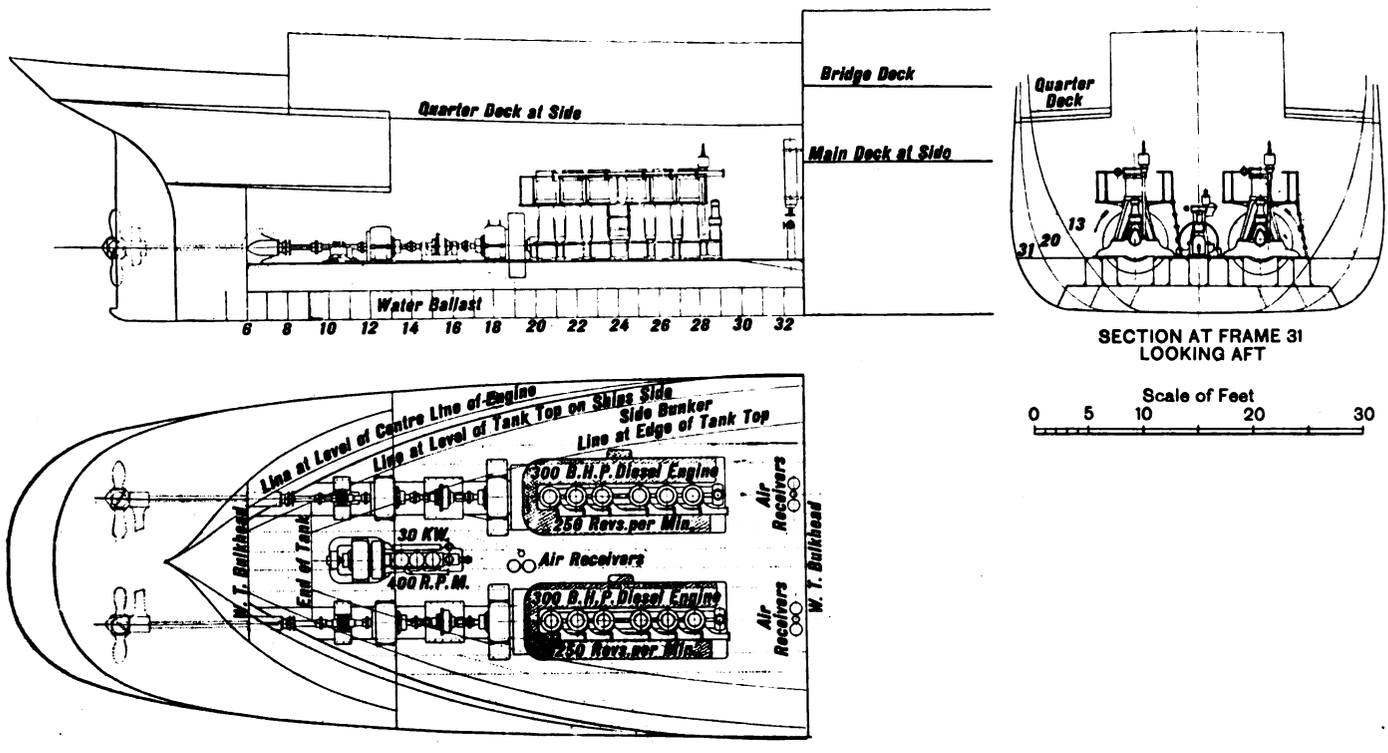

FIG. 1.—GENERAL ARRANGEMENT OF "MIRRLEES' DIESEL" OIL ENGINE FOR AUXILIARY PURPOSES AND PROPULSION OF AN OIL-CARRYING VESSEL OF 1,800 TONS.

Digitized by Google

Diesel or steam engines in any combination. They are further capable of an overload of 10 per cent. for two hours.

The engines are totally enclosed and fitted with an efficient system of forced lubrication, which lessens the attendance necessary and reduces wear and tear to a minimum. Engines have run for periods of two years without any bearings having been adjusted, and on examination at the termination of this period the wear was found to be inappreciable and the bearings were put back to their original adjustments.

One special feature of this engine is its accessibility. All valves are provided with separate removable seats. This enables specially hard and durable metal to be used for the seats and reduces the stopping periods. Since there is a spare valve and seat provided for each working valve and seat, the periodical overhaul of valves can be carried out without a prolonged stoppage of the engine, as the working valve and its seat can be removed and replaced at once by the corresponding spare, the engine started, and the valve last removed attended

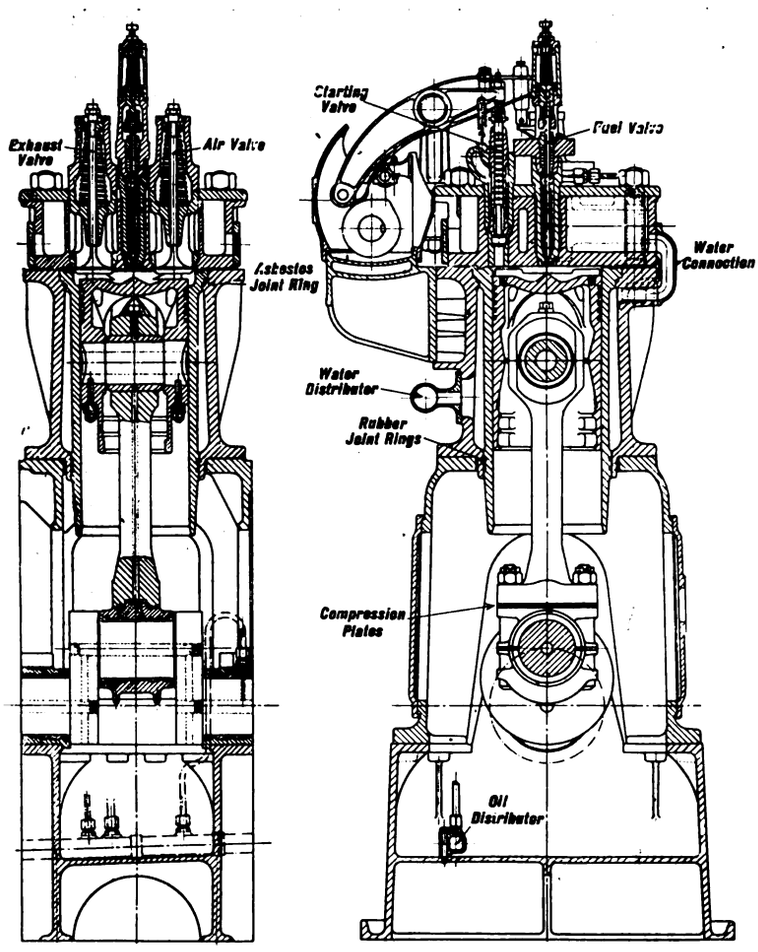

FIG. 2.—SECTIONAL VIEWS SHOWING ARRANGEMENT OF CYLINDER, COLUMN AND VALVES OF A 160 B.H.P. "MIRRLEES-DIESEL" OIL ENGINE Scale, 1:20.

to at leisure. To facilitate the removal of the exhaust and fuel valves (which require to be examined about once in two or three weeks), the levers operating these valves are divided so that, by removing a single bolt, that part of the lever which is above the valve can be swung back clear, enabling the valve to be removed without disturbing the remainder of the valve gear.

Another special feature is the air compressor. This is a two-stage compressor, delivering air at between 600 lb. and 950 lb. per square inch, the air being used for atomising and injecting the fuel into the cylinder. The compressor has a large margin in capacity, and is capable (in addition to supplying the air for fuel injection) of replenishing the starting reservoirs. The whole of the parts of this compressor are metallic, no fibre or vulcanite packings being used. The valves only need to be withdrawn for cleaning about once a month, an operation performed in a few minutes

The third special feature is the governing. When all the load is sudd nly removed the momentary variation in speed does not exceed about 7 per cent. and the permanent variation about 3 per cent.

There are many other special features in the constructional details of the engine which are of particular interest, but for which space is not at present available. The keynote of the whole design has been reliability and accessibility combined with extreme fuel economy.

Fig. 1 shows the general arrangement of one of these engines, and also a vertical section through one of the cylinders.

"Mirrlees-Diesel" engines have also been applied to the propulsion of boats, three of which have been supplied to the Navy, two being for Vedette boats (of 120 B.H.P. or 160 I.H.P. each) and one for a 60 ft. harbour service launch of 100 B.H.P. (130 I.H.P.). Fig. 2 is an illustration of the latter.

In engines of the above sizes, and even considerably beyond them, the necessary reversibility is easily and satisfactorily obtained by the use of either reversible-bladed propellers or of mechanical reversing gears. The boats above mentioned are fitted with the latter.

When the powers demanded exceed the limits imposed by such mechanical devices, the "Mirrlees" system of electrical propulsion is adopted, and this system is considered to offer special features of advantage.

The scheme is shown in the illustration attached and is described as follows: The propelling machinery, as shown on the drawing, consists of two six-cylinder "Mirrlees-Diesel" oil engines, capable of developing 300 B.H.P. each, when running at 250 revs. per min. When proceeding ahead at any speed between full speed and half speed, the engine and propeller shafts are coupled together by means of a combined friction and positive clutch, the speed being varied between these limits by a controlling apparatus fitted on the engines. On each shaft is secured a dynamo capable of developing about 60 B.H.P. at 125 revs. per min. (that is, about 20 per cent. of the full power of the engine at one-half of the engine revolutions). On each propeller shaft is secured a reversible variable speed motor, capable of absorbing the full power of the dynamo. When manœuvring ahead and astern with the propellers, or proceeding ahead at less than half speed, the engine and propeller shafts are disconnected. The dynamos on the engine shafts operate the motors on the propeller shafts, the engines and dynamos running at a constant speed of 125 revs. per min., the speed and direction of rotation of the motors and propellers being controlled electrically by varying the intensity and direction of the current in the fields. In emergency, such as to avoid collision, &c., when running electrically, it is possible to increase the speed of the engine up to its maximum, whereby the dynamos and motors are capable of an increased output for a reasonable period. The electrical arrangements can be so disposed that each dynamo operates either or both motors, thus providing for a breakdown of either the other dynamo or engine. This device has been protected by patents, and its special features of advantage are:—

1. Losses in transmission, as compared with a purely electrical transmission, are avoided at all speeds above half speed ahead.

2. The size, weight and price of the electrical equipment are much less than in a purely electrical transmission.

3. It is anticipated that the handling of the vessel will be quite as satisfactory as that of the latest turbine vessels, in which the maximum power when going astern rarely exceeds 40 per cent. of the maximum power when going ahead.

4. In connection with the electrical apparatus nothing that has not been thoroughly tried on shore is proposed for use afloat.

In conclusion, the scheme above outlined enables full advantage to be taken of the superior economy, as regards fuel, of the Diesel oil engine, whilst avoiding complications of mechanism necessitated by a reversible engine, and it also enables fine gradations to be obtained in the speed control of the vessel on moderate weights and at moderate cost.

Electrical Plant for Marine Installations.

Especial interest attaches to Messrs. Allen's work in the production of electrical plant for marine installations, as those who can call to mind the early days of electricity on board ship will remember what an important part this firm took in pioneering in this field. As might be expected, the results of a long experience are to be found embodied in their newer designs, and the fact that their machinery still continues to command an ever-extending field of application in marine work is ample evidence of the thoroughness with which the various essentials of such a plant have been considered in the design.

Chief of Messrs. Allen's productions in this connection is still the generating plant, and that it is exclusively in use on by far the majority of the ships of the British Navy, and is also to be found in most of the navies of the world, is considered by Messrs. Allen, not without reason, to justify the statement that it has few equals. The steam engine is usually of the compound totally enclosed type, and is fitted throughout with forced lubrication, having generally two cylinders, though occasionally in the more powerful sets the second expansion stage is divided between a pair of low-pressure cylinders, the engine then having three cranks, an arrangement which gives a better balance and more uniform turning effort. The type of engine is well known and need not here be described in detail; suffice it to say that in the two-cylinder types the cylinders and valve chests are all arranged in one casting, the centres being placed as near together as possible, thus making a very compact and well-balanced arrangement. In the three-cylinder types, each cylinder with its valve chest is cast complete, the cylinders being mounted independently of each other on top of the trunk which encloses the working parts, thus avoiding distortional strains in the framing due to unequal expansion of the metal, which would produce faulty alignment of the working parts and consequent excessive wear. The governor is of the crank-shaft type, and provided with hand regulation, permitting of adjustment of the running speed through a considerable range on either side of the normal while the engine is working. When desired, Messrs. Allen also fit a special emergency stop-valve closing gear, which automatically shuts down the steam supply when the speed exceeds a predetermined limit. The materials employed throughout are of the very finest, and a rigid system of inspection and testing obviates entirely the possibility of any faulty material finding its way into any part of the machinery.

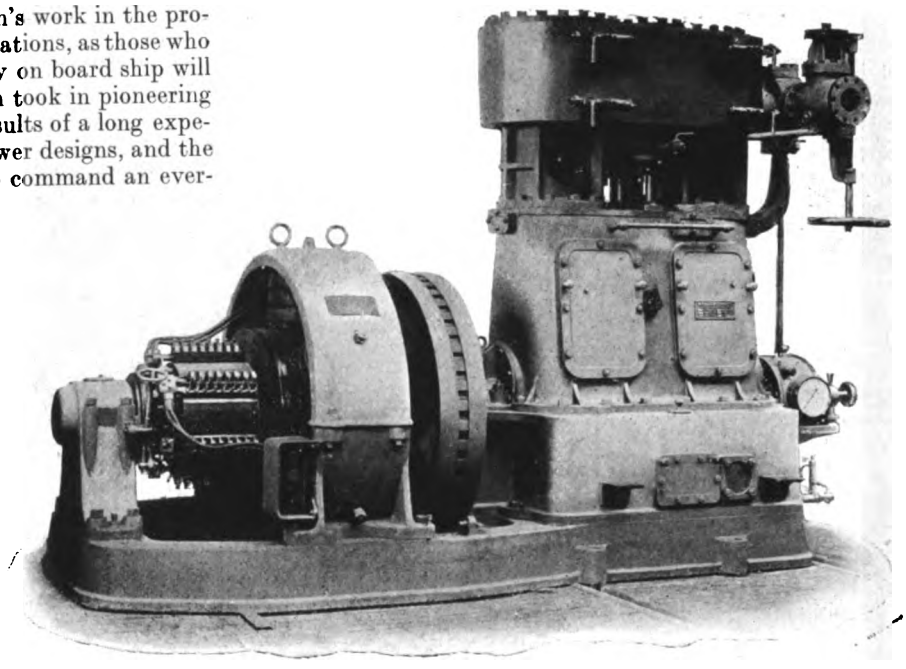

FIG. 2.—ALLEN'S 200 KW. MARINE SET.

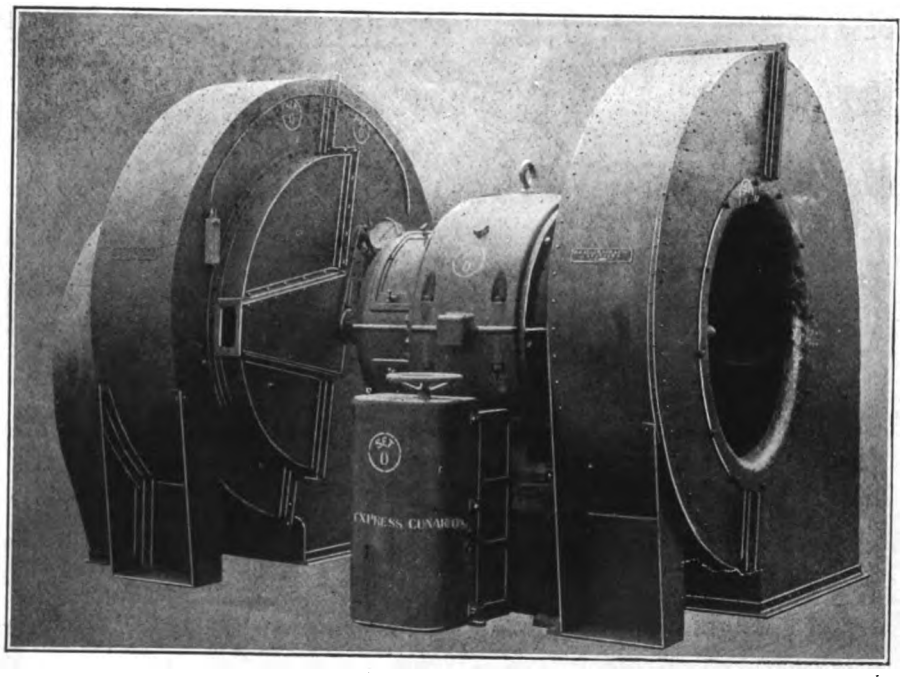

FIG. 1.—ALLEN MOTOR-DRIVEN FAN AS USED ON THE SS. "MAURETANIA."

The dynamo is usually of the continuous-current multi-polar type. The magnet yoke and pole pieces are of cast steel of high permeability, the latter being securely bolted to the inside of the yoke, and the field exciting coils are wound on formers. The armature is of the ordinary slotted type drum-wound, built up of soft annealed plates, and is provided with the usual ventilating ducts. The commutator is of hard drawn copper sections insulated with mica and micanite, and secured together on a cast-iron sleeve; it can be removed entire by simply unsoldering the connections to the armature winding. The commutator bars are of sufficient depth to permit of being turned down a considerable amount without requiring renewal of any parts. The brush gear consists of carbon brushes, carried in a substantial brass guide, and each brush is held against the commutator by a separate spring, so arranged as to admit of the pressure being adjusted and the brushes withdrawn separately for inspection. A neat hand worm-gear is also fitted for adjusting the "lead" of the brushes. The brush rocker and hand-adjusting gear are carried by the outer bearing. The dynamo shaft is flanged to form a coupling for bolting to the end of the engine shaft. A light and rigid under base plate extends completely under both engine and dynamo, and this, by preserving the alignment of the bearings, &c., adds greatly to the life and conduces not a little to the smooth running of the whole plant.

It is only within recent years that the electric motor has begun to supersede the steam engine on board ship for the

Digitized by Google

purpose of driving fans for forcing the draught in the boilers and for ventilating purposes. This appears at first sight a little surprising, in view of the great facility with which such plant can be regulated. On closer investigation, however, it will be seen that there are several practical difficulties attending the adoption of electrical power for this purpose. It usually happens that the fans have to be placed in a part of the stoke-hold where the temperature is exceedingly high, and hence, if electric motors are employed, either special means must be provided for cooling the motors, or the motors themselves must be so constructed as to be able to withstand successfully very high temperatures. Messrs. Allen have carried out a large number of installations on both systems, the latter, however, being a somewhat costly arrangement as the insulating materials employed are naturally of a much more expensive nature, and are such as otherwise greatly to increase the cost of manufacture.

We shall here describe briefly a couple of large installations carried out on the former plan, being those of the ss. "Mauretania" and "Lusitania." Each installation consists of 32 fans arranged in pairs, one electric motor providing the necessary power for two fans. The fan impellers are of the single-inlet type, being 66 in. in diameter, and each capable of delivering a maximum of 33,000 cubic ft. of air per minute against a water pressure of $3\frac{1}{4}$ in. when running at 450 revs. per min. The motors are of the four-pole continuous-current type, completely enclosed, and each capable of developing 50 B.H.P. at a speed of 450 revs. per min. and at a pressure of 110 volts. Owing to the high temperature of the compartment in which these motors have to work, situated as it is above the boilers, a special arrangement for cooling has been adopted. This consists in passing through each motor casing a current of cool air which enters it below the commutator and leaves it at the upper side of the further end of the casing. The air for this purpose is supplied by an auxiliary fan arranged alongside one of the main fan casings, one such fan being provided for each pair of main fans and driven direct from the motor spindle. Each of the main fans is fitted with a water gauge to indicate the draught pressure, and also with a tachometer.

The controllers for these motors are also of Messrs. Allen's manufacture, and by them the speed can be regulated by equal steps from 225 to 450 revs. per min. No-voltage and overload automatic releases are also fitted, giving complete protection to the motors under all conditions. When running at the lowest speed the approximate output of air from each fan is 17,000 cubic ft. per minute at a gauge pressure of 1 in.

The ventilation of the fan room on the "Mauretania" is effected by eight of Messrs. Allen's single-inlet motor-driven fans. The motors are of the totally-enclosed type, and each set is capable of delivering 1,000 cubic ft. of air per minute at a pressure of 1 in. water gauge and at a speed of 900 revs. per min. They are of the four-pole series-wound type, and develop 5 B.H.P. at 900 revs. per min. and 110 volts. Each motor has a separate controlling panel, consisting of one double-pole quick-break switch, tubular fuses and starting and regulating resistances.

The accompanying illustrations show examples of the plant Messrs. Allen have designed for marine work.

De Laval Steam Turbines.

The value and importance of the steam turbine for ship propulsion have come to be recognised mainly as the outcome of experience with this class of prime mover in connection with ship-lighting plants. The De Laval turbine was instrumental in initiating the high-speed turbo-generator into ship work, demonstrating by its light weight and running economies the possibilities of a compact equipment from which electrical energy could be obtained for lighting, and

power purposes. Varied experience both in the Navy and mercantile marine has confirmed the high opinions of steam-turbine pioneers of its ability to run constantly under every conceivable condition without breakdown and with a minimum of attention and cost for repair.

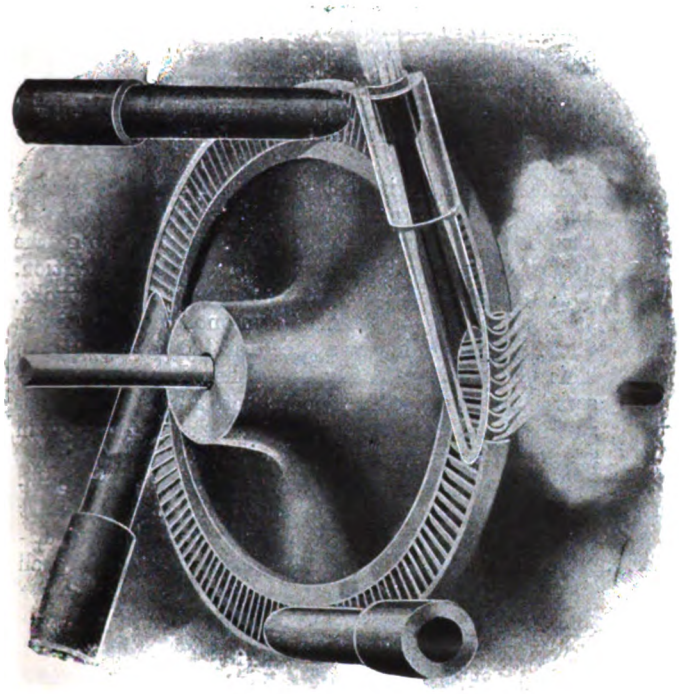

FIG. 2.—EXPANDING NOZZLES AND BUCKET WHEEL OF DE LAVAL STEAM TURBINE.

The De Laval turbines are of the single expansion type arranged with one turbine wheel only, the wheel running at a high speed, which is reduced by gearing so as to suit the dynamo. The steam is expanded in a row of nozzles, and the arrangement of these and the working of the steam is shown in Fig. 2. The general arrangement of the smaller sizes of the De Laval turbine-dynamo sets is shown in Fig. 5, which illustrates a machine seen from above with the cover of the gears removed. The turbine wheel, with its nozzles, is enclosed within the casing to the extreme right of the figure; the pinion and the shaft of the turbine wheel is supported by bearings *m* and *n* and the gear wheels by bearings *h* and *j*. The gear wheel is connected to the armature of the dynamo by a flexible coupling.

The larger sizes of turbines—above 30 B.H.P. or 20 kw.—are constructed similarly to the smaller units except for the arrangement of the gearing. Fig. 3 shows a large turbine-dynamo set seen from above with cover of gears removed. The pinion of the gearing is arranged in two parts and the turbine shaft supported by *three* bearings *m*, m_1 and *n*; the gear wheel is also constructed in two wheels (on the same shaft) separated by the bearing *i*. These larger machines are provided with forced lubrication for the high-speed bearings, an oil pump being

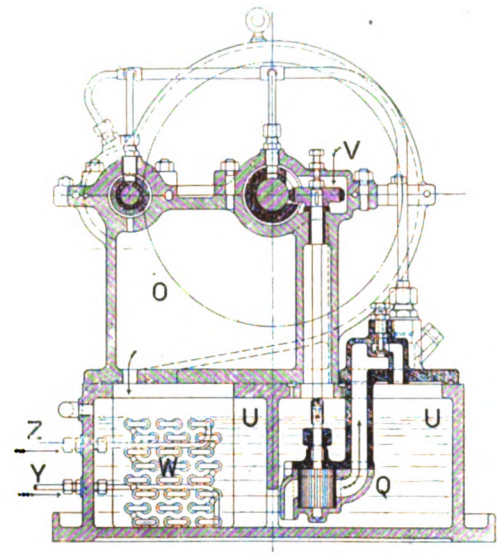

FIG. 4.—GEAR OIL PUMP AS USED ON DE LAVAL TURBINES.

arranged as shown in Fig. 4, this pump being driven by worm gearing from the gear-wheel shaft. The slow-speed bearings are provided with ring lubrication.

The speeds of the electric generators coupled to the turbines are not excessive, the number of revolutions of the smallest unit—3 B.H.P. or 1·625 kw.—being 3,000 revolutions, and that of the larger machines 750 revs. per min. The dynamos are of the ordinary construction, open self-ventilating with carbon brushes and commutating poles. The smaller sizes are two-pole, the larger four-pole.

The turbines are regulated by a centrifugal governor, com-

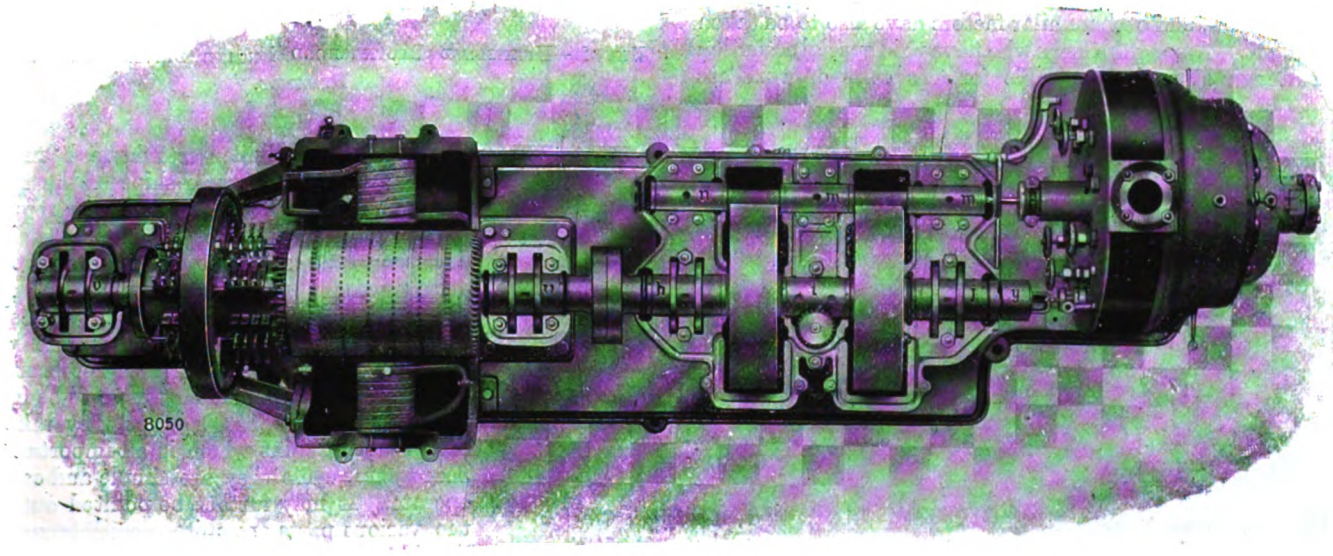

FIG. 3.—LARGE TYPE DE LAVAL TURBINE, SHOWING DOUBLE GEARS.

bined with a double-beat governor valve and also with a throttle valve on the exhaust. The regulation is very accurate.

The turbines for ship work are arranged with steam nozzles both for exhausting to the main condenser of the vessel and

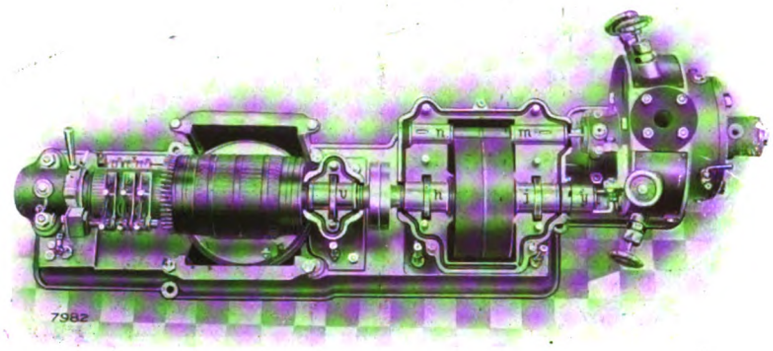

FIG. 5.—SMALLER PATTERN DE LAVAL STEAM TURBINE, SHOWING GEAR CASING REMOVED.

with nozzles for working exhausting either to the atmosphere or to the auxiliary condenser without or with slight vacuum. In addition to this, these turbines are sometimes provided with nozzles to work off the donkey-boiler. Fig. 1 illustrates a ship lighting turbounit with switchboard complete, erected in corner of the main engine-room.

Brotherhood Engines for Marine Work.

The design of engines suitable for driving electric generators on board ship requires that rather different problems should be solved from those met with on land. The atmosphere is none too good for the operation of such machines, the deck to which the set is fixed often moves about in an exceedingly complicated fashion, and other similar factors have also to be taken into account. Among the firms who have paid special attention to the design of engines suitable for this class of work are Messrs. Peter Brotherhood, some examples of whose plant we illustrate in this article.

Fig. 2 shows a standard high-speed enclosed engine fitted with forced lubrication and direct-coupled to two 20 kw. dynamos. The plant illustrated generates current at either 110 or 220 volts, but similar sets could also be used for supplying a small three-wire system, as each generator is so arranged that the pressure from it can be regulated in accordance with the requirements of the load. The engine shown develops 35 H.P. when running at 450 revs. per min., but it may be run at 600 revolutions, and then its output increases to 45 H.P.

Another interesting set consists of an engine direct-coupled to a dynamo which has been designed to be used on either ship or land. This engine is also of the enclosed type, and is fitted with forced lubrication. It has a cylinder 7½ in. in diameter and a 5 in. stroke. It is coupled to a Siemens dynamo, which delivers 7 kw. when running at a speed of 400 revs. per min. This plant, as can easily be gathered from the description, is exceedingly compact, and we are not surprised to learn that many of them are now in successful operation.

Fig. 1 represents a standard 200 kw. set made up of a Brotherhood engine and generator. The engine runs at 400 revs. per min., its cylinders being 14¼ in. and 24 in. in diameter, and 8 in. stroke. Forced lubrication is fitted to all

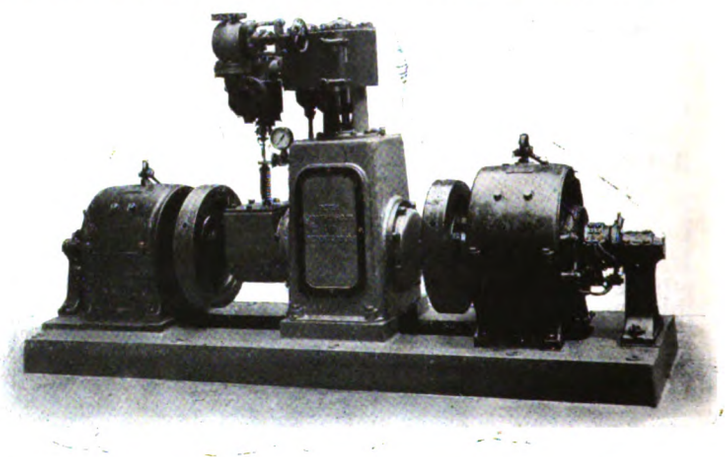

FIG. 2.—HIGH-SPEED BROTHERHOOD ENGINE DRIVING TWO 20 KW. DYNAMOS.

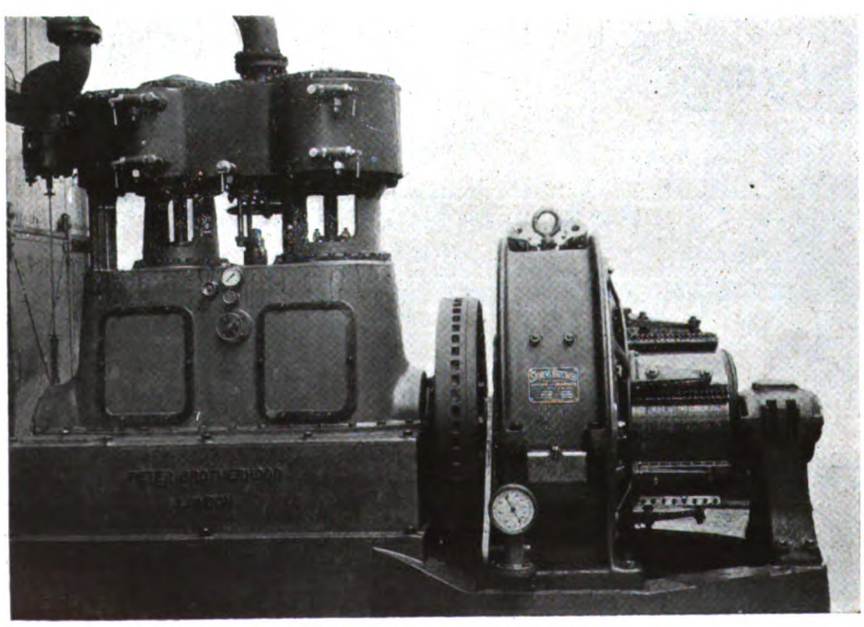

FIG. 1.—STANDARD 200 KW. BROTHERHOOD ENGINE AND GENERATOR.

the bearings. Similar sets have been supplied in large numbers to ships of the Royal Navy for lighting purposes, and are required to develop the full output against a back pressure of 25 lb. per square inch above the atmosphere.

A study of these photographs will show that in designing engines for marine work Messrs. Peter Brotherhood have not been unmindful of the problems that have to be faced. The sets are compact, so that they take up little space, a point which is all-important on board ship, while they are simple and easy to operate. It may further be pointed out that the various parts are quite accessible, so that should any repairs be necessary the damaged portion can be got at with a minimum of trouble. This advantage can only be appreciated in its proper fulness by those whose fortune (or misfortune) it has been to carry out repair work in the circumscribed space usually allotted to electrical plant on board ship. In short, Brotherhood engines are essentially suitable for marine work.

Electrically-driven Shipyard Cranes.

BY H. H. BROUGHTON.

Summary.—Certain detail work which affects the performance of all types of electric cranes is briefly considered in the first part of the article. In the second part descriptions are given of several cranes and crane systems which are in use in a number of the principal shipyards. Yard cranes, building slip equipments and fitting-out basin cranes are dealt with.

Probably in no branch of engineering is it more necessary to expedite the handling of material than in the building of ships. At the present time the shipbuilding industry is characterised not only by work of enormous magnitude but also by rapidity and economy of construction, and the remarkable achievements of recent years are due in large measure to the development of appliances well suited to the duties which they have to perform. Foremost amongst these appliances are electric cranes.

In any industry, more particularly in the shipbuilding industry, in order to promote rapid and economical construction it is necessary to reduce to a minimum the cost of unskilled labour, or, in other words, the cost of unproductive labour. When it is remembered that it is economical to instal a machine costing £500 to take the place of a labourer at £1 per week it will be seen that huge outlays of capital can profitably be incurred in cases where much material has to be handled. As an example a type of fixed crane may be quoted much used in the fitting out of vessels. Such a crane may be, and often is required to lift loads up to 150 tons in weight anywhere in an area defined by two concentric circles having radii of 30 ft. and 100 ft., the maximum load being lifted at 5 ft. per minute. Moreover, loads up to 30 tons in weight may be dealt with at a radius of 140 ft. The average cost of such a crane is £35,000. Another example is the crane equipment installed over the building slips in a yard turning out the largest vessels. The cost of a slip equipment (including the gantry) runs well into five figures.

It is unnecessary in this article to set forth the many advantages of electrically-driven cranes over all other types. Notwithstanding the united efforts of pessimistic mechanical and hydraulic engineers to oppose the introduction of electric driving, the electric crane has during the last 10 or 15 years ousted practically every other type of crane, and new works, docks and harbours are, almost without exception, provided with electrically-driven cranes.

When an installation is being planned it is advisable carefully to consider the question of providing a battery-booster plant for equalising the load on the main generators. If the load fluctuations follow one another rapidly, and if the generating plant is of sufficient size to withstand the overloads, the conditions may be met by over-compounding the generators. If, however, the motors connected deal intermittently with comparatively heavy overloads, the installation of a battery and booster would result in a considerable saving in the first cost of the generating plant and feeders, and would admit of the constant operation of the plant at a steady load. The saving which is effected by the proper application of a battery may exceed 25 per cent. per annum on the capital expenditure.

In a series of articles contributed to THE ELECTRICIAN the writer described the electrical and mechanical arrangements common to all types of electric cranes, so that an extended treatment on these lines is unnecessary. There are, however, a number of important points which the crane user would do well to bear in mind in drawing up specifications for new cranes, and it is these which will be discussed before noteworthy examples of modern shipyard cranes are described.

STRUCTURAL DETAILS.

Every care must be taken to ensure that the brakes on the several motions are of suitable design. Generally speaking, at least two independent brakes are provided on the lifting mechanism to check the descent and to hold the load. In some cases as many as four independent sets of brake-gear are provided. On account of the high speeds at which modern cranes are worked efficient brakes are usually fitted on the slewing, traversing and travelling mechanisms.

The four types of brakes most used are : (*a*) Electric or rheostatic, (*b*) electro-mechanical, (*c*) mechanical and (*d*) hydraulic. Of these, perhaps, the best known are the electric and electro-mechanical types.

Electric brakes give complete control over the speed with light or heavy loads, and are cheaper than mechanical brakes. If properly operated excessive strains on the gearing are avoided. They depend for their action upon the fact that under certain conditions if a motor be driven mechanically, and at the same time short-circuited by a variable resistance, current will be generated ; the current generated, and hence the braking effort, depending upon the resistance and the speed. Since current is generated only as long as the armature is in motion it follows that an electric brake cannot be used for retaining the load. For this purpose a holding brake must be provided. An objection to the electric brake when applied to a busy crane is that little time is allowed for the motor to cool,

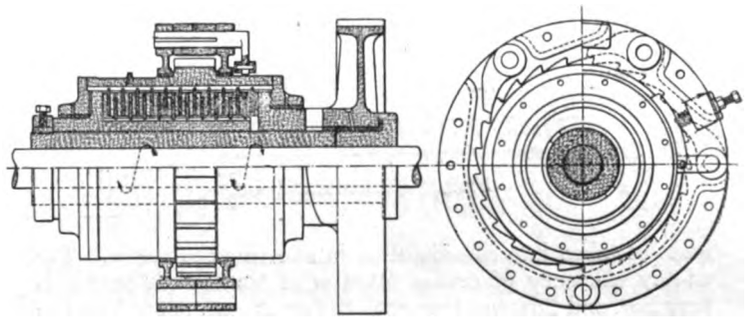

FIG. 1.—WESTON TYPE MECHANICAL LOAD RETAINING BRAKE.

as current is passing during hoisting and lowering, and to avoid overheating the question of rating must be carefully considered. A further objection is that since the braking torque acts direct on the motor armature any breakage of the gear wheels or intermediate mechanism would leave the load free to descend.

Electro-mechanical brakes (wrongly called electric brakes) are in reality mechanical brakes of the band, shoe or disc type provided with an electro-magnetic release. The arrangements are such that the brake comes into action if the current supply be interrupted, intentionally or otherwise. To minimise the cost it is usual to apply the electro-mechanical brake to either the motor spindle or to the second motion shaft, and as in the electric brake, fracture of the wheel teeth or of any of the shafts leaves the load free. It should here be stated that when polyphase alternating-current motors are used to operate cranes, brake motors should be used in preference to polyphase electro-magnets.

In nearly all heavy cranes mechanical load-retaining brakes of the "Weston" type are fitted on the winding-drum shaft, or on the shaft next to it, and when properly designed they will work for years without attention. For satisfactory performance the sliding velocity must not exceed 30 ft. per second, and the "brake work" (per square inch) must not be greater than 24 ft. lb. per second. A typical brake of this kind is shown in Fig. 1, and the structural details will readily be inferred from the drawing. When the load is being lifted the brake is locked

Digitized by Google

and revolves with the spindle, but when lowering the casing is prevented from turning by means of a ratchet wheel and pawls, the friction between the revolving and fixed parts constituting the brake. Current is required to lower the load, and this fact

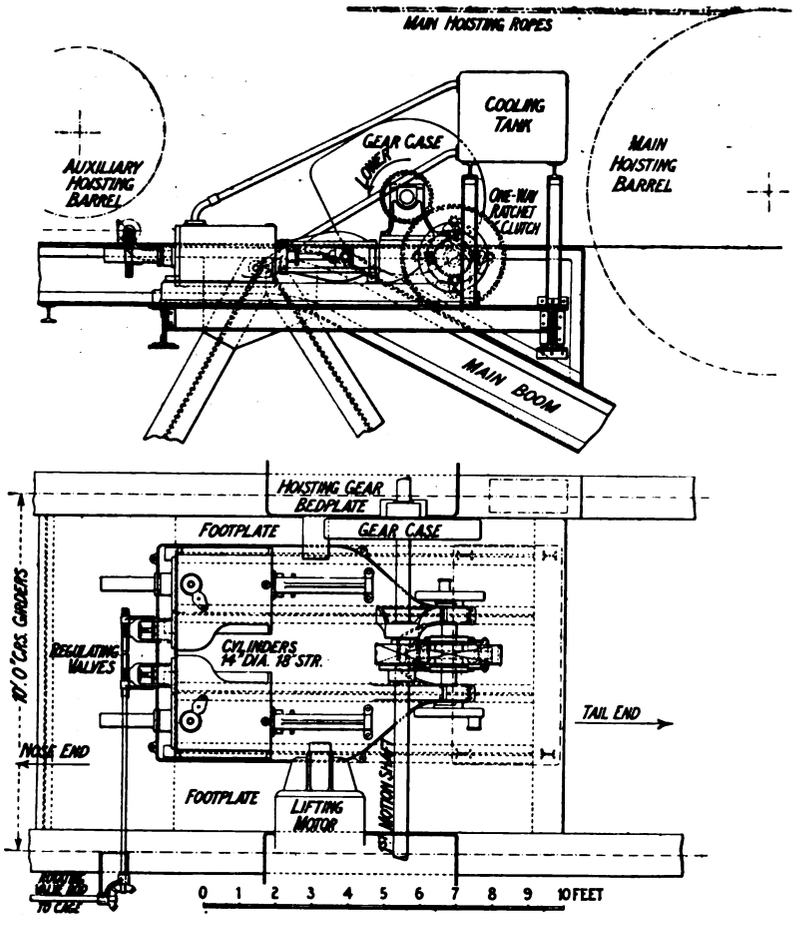

FIG. 2.—HYDRAULIC BRAKE.

must be taken into consideration in selecting the motor. The all-day efficiency of cranes fitted with mechanical brakes is very low, and this, together with the great cost, neutralises the advantages to some extent.

The hydraulic brake shown in Fig. 2 has been used on many of the heavy giant and titan cranes constructed by Messrs. Stothert & Pitt, and has proved entirely satisfactory under the most exacting conditions of service. The brake consists of two hydraulic cylinders fitted with pistons, guides and cross-heads. To prevent overheating, the cylinders are water-jacketed. By-passes connect the ends of the cylinders, and throttle valves are provided for opening or closing the ports. The pistons are actuated from crank-discs which are driven by the main lifting gear of the crane when the load is being lowered. A ratchet free-wheel clutch is fitted in order that the hydraulic pistons may remain at rest when the load is being lifted, so that no resistance is opposed to hoisting.

Where several brakes are provided, each should be thoroughly tested with the proof load before the crane is accepted. Electro-mechanical and mechanical brakes should, independently, be of sufficient size satisfactorily to sustain and to lower the load. During the test on the mechanical brake the electro-mechanical brake should be disconnected and vice versa. Moreover, tests should be made which approximate to normal operation, so as to determine the temperature rise of the brakes. Electrical engineers have long recognised that the output of a dynamo electric machine is limited by rise of temperature, and it is to be regretted that many mechanical engineers forget that some machine parts must have not only sufficient strength to resist the forces acting but also cooling surface of such an area and disposed in such a manner as to get rid of the heat which is generated in overcoming frictional resistances.

Another matter which receives insufficient attention is the provision of appliances which make it impossible either suddenly to start or to stop the several motions of a crane. It is desirable to accelerate and retard quickly, and the gears, shafts and structural work must be proportioned to withstand the forces due to the inertia of the moving parts. The travelling and slewing motors, and in some cases all the motors on high-speed cranes should be provided with some kind of elastic connection or slipping drive which can be set positively to slip when the torque exceeds a certain amount. Such devices are inexpensive; they ensure smooth running and enable unskilled operators confidently to work the cranes at their utmost speeds and capacities.

In the main all the gearing should be of steel, the pinions being made from well-hammered high carbon or nickel steel billets, and the wheels of superior quality mild steel practically free from blow holes and shrinkage cracks. With the exception of the slewing curb, and in some cases the barrel wheel and mating pinion of the lifting mechanism, the gears should be machine cut. Involute teeth are now generally used on account of their advantages over the cycloidal form. Overhung wheels and pinions should always be viewed with suspicion. There is a tendency on the part of crane builders to use overhung pinions on the motor spindles, and the practice is bad, for quite apart from mere noise such wheels give trouble in many ways. All high-speed gears should be enclosed in dust-proof cases.

Worm-reducing gears, although widely used on the Continent, are fitted on comparatively few cranes in this country. When properly designed and constructed they are as reliable and have as high an efficiency as cut spur gears giving the same speed reduction. Here again we desire to emphasise the fact that the output is generally limited by the rise of temperature and not by the mechanical strength of the teeth. As long as the question of temperature rise is neglected, worm gears will not give satisfaction. Worm gears are generally constructed by specialist firms, and we would suggest that such gears be subjected to a crane rating test of, say, one hour's duration, or to an intermittent run of six hours' duration under a specified load factor, the temperature rise not to exceed 150°F.

The lifting and traversing ropes should be of extra special flexible plough steel quality with a factor of safety of seven,

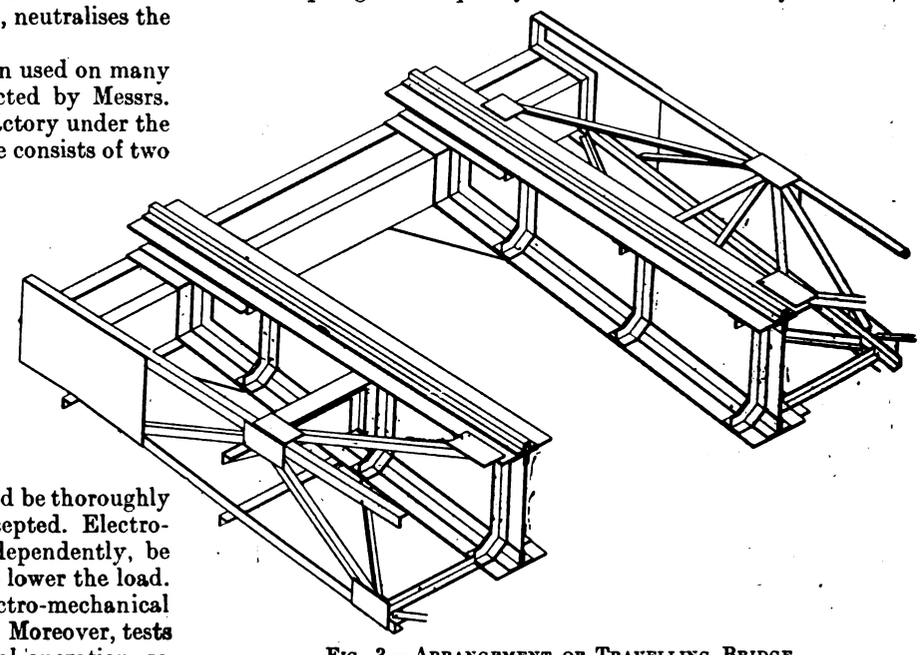

FIG. 3.—ARRANGEMENT OF TRAVELLING BRIDGE.

and the diameter of the winding drums should not be less than 24 times the diameter of the rope.

For ordinary overhead travelling cranes of medium span the best form of cross girder construction to use is shown in

diagrammatic form in Fig. 3. From the drawing it will be perceived that girders of the single web type are braced to light outrigger lattice girders, which give great stiffness without excess of material, and the open nature of the construction admits of thorough inspection at all times. The structural work of shipyard cranes is liable to corrode on account of the exposed positions in which the cranes have to work and of their proximity to the sea. It follows, therefore, that all parts must be accessible for inspection and painting, and so arranged as to allow a free circulation of air through them. No plates or sections less than $\frac{3}{8}$ in. in thickness should be used except for detail work, platforms and so forth.

In adopting electric driving engineers should endeavour to arrange the machines in such a way that a comparatively small number of different sizes of motors are required. By so doing few spares have to be stocked, and switchgear and accessories may be standardised. The writer has shown that the same principle can be applied to cranes of widely varying capacities and speeds.*

Generally speaking, all the motors and brake-releasing electromagnets should have a one hour rating with a rise of temperature not greater than 75°F., or, better still, the rating should be based on the load factor to which the motors are subjected. Controllers, switchgear, and resistances should be of robust mechanical construction, and all live parts protected in an efficient manner. Care must be taken to ensure that the whole of the wiring work is carried out in a thoroughly satisfactory manner. No cables other than "Association" quality, taped, braided and compounded, of not less than 600 megohms grade should be used, and the wiring should be run in galvanised steel barrel (free from burrs), with screwed joints, and inspection boxes at the bends, outlets being bushed to avoid abrasion. The entire electric equipment and each motor circuit on a crane should be protected against overloads and short-circuits by circuit-breakers or enclosed fuses. As a safeguard against mechanical injury, limit switches are generally provided which interrupt the supply in the event of the motion being carried too far. Hammer cranes and jib cranes are usually provided with an indicator which records the working radius and the safe load at that radius.

Apart from overhead cranes and ordinary jib cranes which resemble those used in all engineering works, shipyards are provided with special cranes in the plate and stock yards, over the building slips and at the fitting-out basin. The remainder of this article will be devoted to the description of a number of these special cranes, and for convenience they are taken in the order named above.

YARD CRANES.

Double cantilever and gantry cranes are generally used in the plate and stock yards. They are characterised by their great size, and by the high speeds of the several motions. Thus the capacity and dimensions of the yard cranes installed at the works of Messrs. Vickers, Sons & Maxim, Barrow, by the Brown Hoisting Company, are as follows* :—

Trolley travel 159 ft. 1½ in. each way from the centre of the crane, or a total of 318 ft. 3 in. centre to centre of the extreme positions of the hoist block. The maximum load is 5 tons, which can be lifted and travelled through the entire length of the travel of the trolley on the runway. An open trestle structure supports the cantilever, and pieces of 60 ft. in length can be carried through the pier without turning. The double tracks on which the cranes run are gauged 30 ft. 6 in. centre to centre. A motor of 85 B.H.P. output drives the several motions, and under full load the lifting speed is 200 ft. per minute, the travelling speed of the whole crane is about 300 ft. per minute, and the trolley may be traversed at any speed up to 750 ft. per minute.

A 5-ton double cantilever crane constructed by the Appleby Crane & Transporter Co. (Ltd.), and installed at Messrs. Beardmore's Shipyard, Dalmuir, is shown in Fig. 4. The total range of traverse is 240 ft., and the total height of lift above rail level is 22 ft. From the photograph it will be seen that the cantilever is of very light construction, so as to minimise the effect of wind pressure. An under-carriage of double portal form supports the cantilever. It is mounted upon eight pairs of wheels, arranged two pairs under each leg, and compensating trucks are used in order to ensure that all the wheels bear evenly on the rails. The double tracks are pitched at 25 ft. centres apart, and the wheel-base of the crane is 52 ft. 3 in.

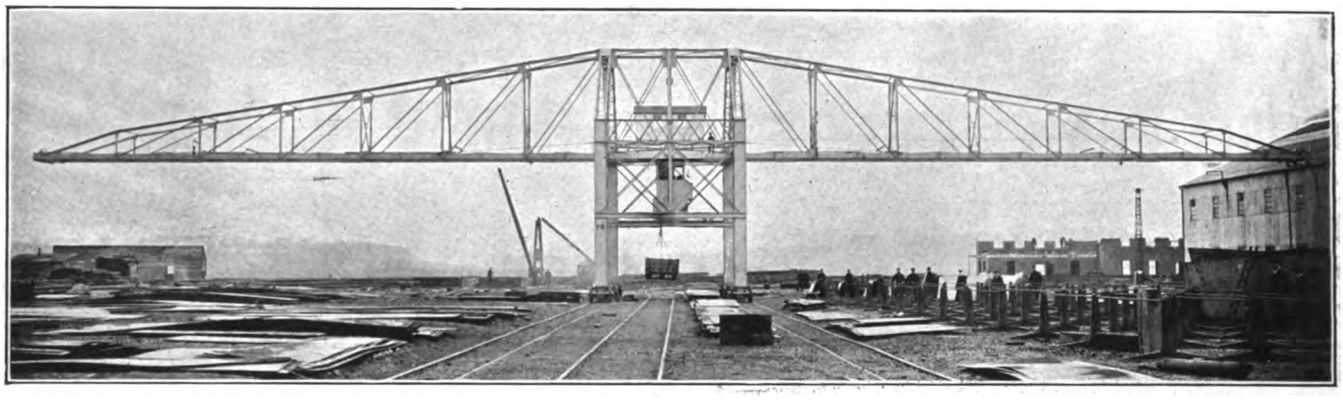

FIG. 4.—5-TON DOUBLE CANTILEVER CRANE, BY APPLEBY'S LTD.

With full load, lifting is at the rate of 100 ft. per minute, traversing and travelling at 400 ft. per minute and 300 ft. per minute respectively. Loads of less than 5 tons in weight are lifted at proportionately higher speeds, and by means of the controllers the speeds can be reduced to any desired extent. The motors, of which there are two, are of 50 B.H.P. at 500 revs. per min. Lifting and traversing motions are effected by the same motor, and the mechanism is arranged in such a way as to admit of each motion being performed singly, but not simultaneously.

The lifting and traversing mechanisms are fixed in a weather-proof house on the centre line of the crane immediately above the trolley track, and the whole of the controlling gear is fixed in a cabin placed in such a position as to enable the operator to have an uninterrupted view of the hook and of the working field of the crane.

Gantry, or bridge cranes, as they are called, of considerable size and capacity are used in a number of yards on the Continent and in America. If so desired they may be made with single or double cantilever extensions. When the span is large it is customary to fix the bridge at one end to a stiff portal frame having a large wheel-base, and hinge the other end to a △-shaped trestle. To give the necessary lateral stiffness to the structure, lattice frames are fitted which extend diagonally on both sides from the centre of the bridge to the portal.

In the gantry cranes made by the Brown Hoisting Company,

* THE ELECTRICIAN, October 25, 1907.

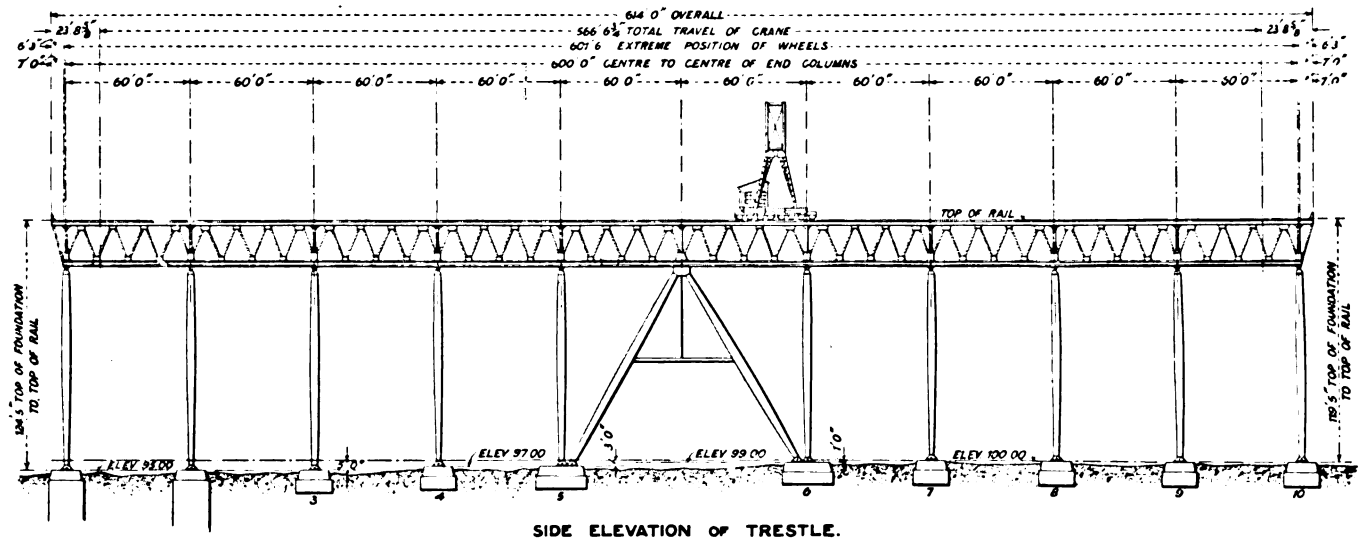
Digitized by Google

the girders are hung to the movable piers in such a way that if the tracks upon which they run get out of parallel or out of level, as frequently happens, or if by reason of slippery rails or other causes, one end of the crane gets behind or ahead of the other, the crane can yet be operated safely and satisfactorily within reasonable limits. No attempt is made to connect the bridge to the legs rigidly. At one end it is pivoted to a double truck pier, and at the other end it is suspended from a single shear or pier by means of a universal connection.

The girders or bridge trusses are designed to give maximum strength with the smallest dead-weight and area of material, with the members of such shapes and so arranged in the trusses as to expose the least possible surface to wind pressure.

BUILDING SLIP EQUIPMENTS.

There are half a dozen or more modern systems of building slip crane equipment, and it is impossible without careful consideration to say which of them is best suited to a certain class of work or arrangement of yard. An equipment involves a large outlay of capital, and in every case full care must be taken to select the best. The best system is the one which enables material to be placed in position at minimum cost. It is generally admitted that the crane system is superior to the side derrick system. The first cantilever crane installed at Cramp's Shipyard, Philadelphia, is said to have placed in position a sternpost weighing 18 tons in about 20 minutes, taking it from trucks at the front end of the yard with but a few men,



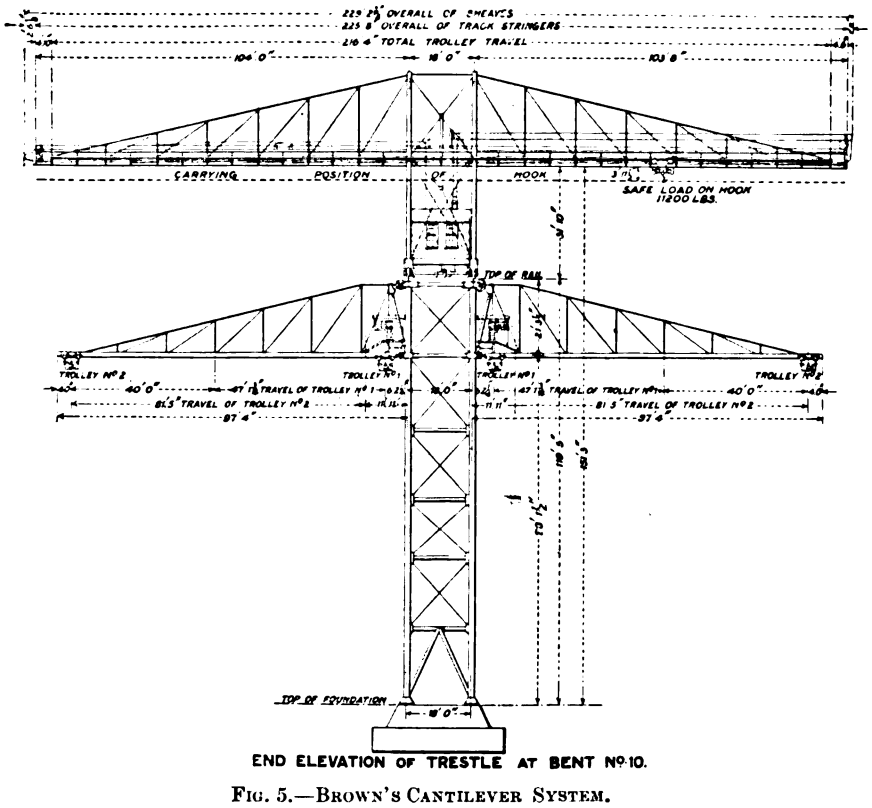


FIG. 5.—BROWN'S CANTILEVER SYSTEM.

A single motor, driving through friction clutches, is used to operate all the motions of the Brown gantry crane. The speeds of these cranes of 5 to 10 tons capacity and of 200 ft. to 250 ft. span are as follows: Lifting full load, 100 ft. to 300 ft. per minute; travelling with full load, 300 ft. to 900 ft. per minute; traversing with full load, 500 ft. to 1,200 ft. per minute. Such speeds can only be attained by cranes possessing a proper amount of flexibility and little inertia.

an operation never before accomplished in less than two or three days and with many men.* After the launch of the ship the same crane cleared the ways in four hours.

The essentials of a building-slip crane equipment are: (i.) Efficient service over the whole berth, (ii.) many cranes of reasonably large capacity and high speeds, (iii.) provision for working the cranes in concert, (iv.) minimum interference with operations along the sides of the ship, (v.) minimum obstruction of daylight, (vi.) adequate means of supporting and manipulating the riveting appliances (vii.) railway service to each crane.

We shall here describe several equipments that have been installed in various shipyards during the last six or eight years, and which conform more or less closely to the requirements stated above. For more detailed particulars of a number of important overhead crane equipments the reader is referred to an article in THE ELECTRICIAN (August 27, 1909).

A typical example of the "Cantilever" system, installed at Messrs. Harland & Wolff's Shipyard by the Brown Hoisting Company, is shown in Fig. 5. From the illustrations it will be perceived that the equipment consists of a gantry or trestle 614 ft. long and 18 ft. in width, placed between two berths, on the top of which a balanced double cantilever crane travels. There are also two side cantilever cranes for taking the hydraulic riveting machines. The gantry is of sufficient height to bring the underside of the crane girder 151 ft. above the ground.

The double cantilever crane extends 104 ft. on each side of

the gantry, and can thus serve any part of either of the ships which are being built on the two slips. Loads up to 5 tons in weight can be handled by the crane, and the rate of travel is 400 ft. to 600 ft. per minute (depending on the load and wind pressure). Cross-travel is at the rate of 400 ft. to 800 ft. per minute. The speed of hoisting is 200 ft. to 250 ft. per minute with maximum load. A single motor of 80 B.H.P. output is used for driving the crane.

Cross-travel of the trolley is accomplished by two drums winding wire rope connected to the trolley. These drums are mounted on a shaft which is never reversed. When one drum is thrown into gear with the driving shaft the other is disconnected and remains idle, so that as one winds the other pays out. The drums are kept in the same relative position by means of a return loop, or small wire rope, which is wound in an opposite direction to the main ropes.

Lifting is accomplished by a single drum, and the load is lowered by gravity, a powerful brake being provided to check the descent. The resultant force of the crane under load is kept within the proper limits by a counterweight which can be moved along a track on the cantilever arms above the load trolley. Wire ropes connect the counterweight to the trolley in such a way that the former automatically takes up a position on one arm of the crane corresponding to the position assumed by the load on the opposite arm. When unusually heavy loads have to be dealt with an additional weight can be added to the counterweight, and if so desired the "arm" of the balance weight can readily be altered.

minute, and the travelling speed along the gantry is 50 ft. per minute. The lengths of travel of the bridges on each crane are about 47 ft. and 81 ft. Motors of 6, 1¼, 1¼, and 50 B.H.P. are used for lifting, trolley cross-traverse, bridge travel and crane travel respectively. The controllers, the main travelling motor and the two bridge travelling motors are located in the operator's cabin. On each bridge are two motors, one for cross-traverse and one for hoisting, and these can be controlled from the riveting position in the ship.

The "Overhead Crane" system is used in a number of yards engaged on the largest vessels. In an equipment of this kind a gantry is erected over the berth which supports a number of travelling bridges, and walking jib cranes are provided on each side of the berth immediately underneath the bridges. Swing jibs are sometimes fitted to the trolleys of the overhead cranes. In the new Harland & Wolff equipment, however, each bridge supports two complete travelling cranes with lifting, traversing and travelling motions.

This equipment was described at some length in a recent issue of THE ELECTRICIAN,* but a further note must be given, as no article on shipyard cranes would be complete without a reference to the largest slip equipment in this or in any other country. The photograph (Fig. 6) gives but a poor idea of its magnitude. On the right will be noticed a gantry which in its day, and that not very long ago, was probably of record size, and this serves to give some idea of the progress made during the last 10 or 15 years.

The gantry, 840 ft. long by 270 ft. wide, covers two berths, and consists of three parallel rows of steel towers rigidly connected together at the top, both longitudinally and transversely, by means of lattice girders. The towers, approximately 170 ft. high, are pitched at 80 ft. centres apart, and the distance between the rows is 121 ft.

A revolving cantilever crane (seen end on in Fig. 6) of 135 ft. radius runs on a track placed directly above the centre row of towers. This crane is of the four motor type, with lifting, racking, slewing and travelling motions. The cantilever arm is 181 ft. above the ground, and loads up to 3 tons in weight, can be dealt with at the maximum radius, and 5 tons at a radius of 65 ft. The speeds are as follows: Lifting, 5 tons at 125 ft. per minute and 3 tons at 205 ft. per minute; racking, 5 tons at 150 ft. per minute; slewing, 5 tons at 400 ft. per minute at jib head; and travelling, 5 tons at 200 ft. per minute. The lifting and travelling motors are each of 70 B.H.P. output, and the slewing and racking motors are of 15 B.H.P. The crane is controlled from a cabin mounted in the jib.

Some distance below the track for the cantilever crane, runways for the travelling bridges and for the walking jib cranes are fixed on the inside of the outer towers and on both sides of the inner towers. There are six travelling bridges and ten jib cranes, three of the former and five of the latter per berth.

Each travelling bridge consists of two open type girders rigidly tied together by stiff lattice frames. Rails are fixed to the bottom flanges of these girders for the purpose of carrying two 10-ton travelling cranes. To place in position heavy stern frames and propeller brackets tackle for handling 40-ton loads can be suspended from eye bolts fitted to the two bridges nearest the water. The travelling cranes may be controlled from a cabin on the bridge or from below at the riveting position. The constants are set forth below:—

Bridge—Span 113 ft. 4½ in., travelling speed 100 ft. per min., motor 40 B.H.P.

Travelling cranes—Load 10 tons, span 43 ft. 3¼ in., height of lift 126 ft., travel of hook 33 ft. 10¼ in.

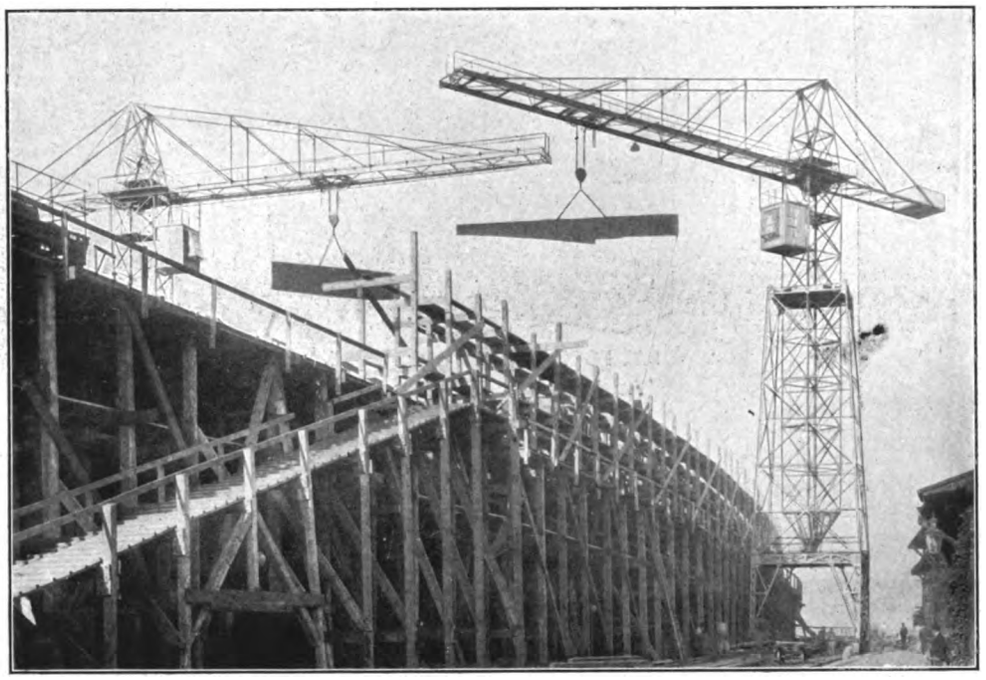

FIG. 8.—BUILDING SLIP EQUIPMENT, BY THE M.A.N. CO.

Speeds—Lifting 10 tons 15 ft. per min., traversing 15 ft. per min., travelling 30 ft. per min.

Motors—Lifting 25 B.H.P., traversing 5 B.H.P., travelling, 5 B.H.P.

The walking jib cranes have a height of lift of 123 ft., and are arranged two on each side of the centre row of towers and three on the inside of each of the outer rows. They run on single rails below the travelling bridges, and are designed to lift 5 tons at a radius of 54 ft. The lifting speed is 100 ft. per minute, the travelling speed 100 ft. per minute, and slewing is at the rate of 250 ft. per minute at the jib head. 50 B.H.P. motors are used for lifting, and for travelling and slewing motors, of 20 B.H.P. and 5 B.H.P. respectively are used. All the control gear for each crane is placed in a cabin fixed near to the junction of the jib and the vertical post.

Access to the cranes and to the working parts of the cranes is afforded by means of protected staircases, platforms and ladders.

"Henderson's" system, shown diagrammatically in Fig. 7, consists of a number of wire-rope cableways (suspended lengthwise over the building berth) carried at both ends on cross-

* August 27, 1909.

Digitized by Google

girders, placed transversely, and supported by lattice-work columns. Each cross-girder is constructed in two parts with a clear space between to admit of the passage of the cables for transverse movement, and rails are provided on which travel the end carriages to which the cables are attached. On each end carriage is mounted a motor-driven traversing mechanism, and the two sets of gear are controlled simultaneously by the operator from the load trolley.

The load carriage or trolley is constructed of steel sections, and is provided with a suitable cage for accommodating the operator and the controlling gear. A single motor drives both the travelling and lifting mechanisms. The trolley is moved along the rope by connecting the motor through friction and spur gearing to a shaft on the ends of which two rope drums are keyed. Two wire ropes are stretched from end to end of the cableway, and each rope is coiled on its drum a sufficient number of times to prevent slip in the opposite direction to that in which the trolley is travelling. The load is lifted on four parts of rope, reeved double, the two parts coiling on the barrel, and the loop passing round a compensating pulley fixed to the trolley. Mechanical friction brakes are fitted to both travelling and lowering motions, with operating levers arranged within easy reach of the driver.

Two equipments have been installed over the building slips at Palmer's Shipyard, Jarrow. The first, with three load handling units, serves a berth 500 ft. long by 100 ft. wide, and the second, with four load handling units, serves two berths each measuring 700 ft. by 75 ft. The speeds are: Of longitudinal travel, about 500 ft. per minute; hoisting, 3 tons 100 ft. per minute; cross traverse, about 25 ft. per minute. Three-phase current at 440 volts 30 ~ is used. The arrangement of the current collectors is as ingenious as any part of the equipment. The five trolley wires are arranged in a horizontal plane, with steel supporting cables at each side held apart by distance pieces pitched at 85 ft. centres. Into the distance pieces are fixed the insulator bolts for carrying the ears which hold the trolley wires. The wheel type collectors are mounted upon a light four-wheeled bogie which rests on the upper surface of the supporting cables. Flexible conductors are brought down to the cab, and the pull on the bogie is taken up by steel cable connections between it and the trolley. The trolley wires are supplied with current by three-core flexible conductors from a distribution board fixed on one of the cross-girders. Each cableway is protected by an overload circuit-breaker mounted upon the distribution board, and the board is itself energised by a three-core cable which passes up one of the inclined columns at the end of the berth.

Revolving tower cranes, either fixed or movable, are used in a number of shipyards on the Continent for serving the building slips, and for yards turning out small vessels they appear to have advantages over other types of cranes. In a Paper on Cranes for Shipbuilding Berths,* Signor Piaggio suggested that an equipment for three berths for ships of, say, 460 ft. long might be installed as follows: The three berths should be placed at a distance of 100 ft. between centre lines, and the centre of each crane respectively 44 ft. from the lateral berth's centre lines. The fixed revolving tower cranes should be eight in number, each of 2½ tons lifting capacity, in two rows, four in each. The height of the horizontal jib from the ground should be about 100 ft. for the four forward, 82 ft. for the two aft and 90 ft. for the central ones. All the cranes should have a working radius of 82 ft., and three independent motors, one for lifting, one for traversing the trolley and one for slewing. The speeds should be as follows: Lifting speed 80 ft. per minute, traversing speed 95 ft. per minute, slewing speed at the extremity of the jib 400 ft. per minute.

Many portable cranes of this type have been installed at the Bremer Vulcan Shipyard, Vegesack, and at the Actien-Gesellschaft Weser in Bremer. For particulars of these the reader is referred to a Paper by Mr. Alexander Murray on the Introduction of Cranes in Shipyards.† Two such cranes, designed and constructed by the Maschinenfabrik Augsburg-Nürnberg, and installed at the Kaiserliche Werft in Kiel, are shown in Fig. 8. Loads of 6 tons can be dealt with at a radius of 39 ft., 4½ tons at 48 ft. 6 in. radius, and 3 tons at 78 ft. radius. The speeds under full load are: Lifting 52 ft. per minute, slewing 94 ft. per minute, traversing 65 ft. per minute and travelling 197 ft. per minute. Separate motors are used for each motion, 28 H.P. for lifting, 7 H.P. for slewing, 6 H.P. for traversing and 20 H.P. for travelling. A general idea of the arrangement of these interesting cranes will be obtained from the photograph.

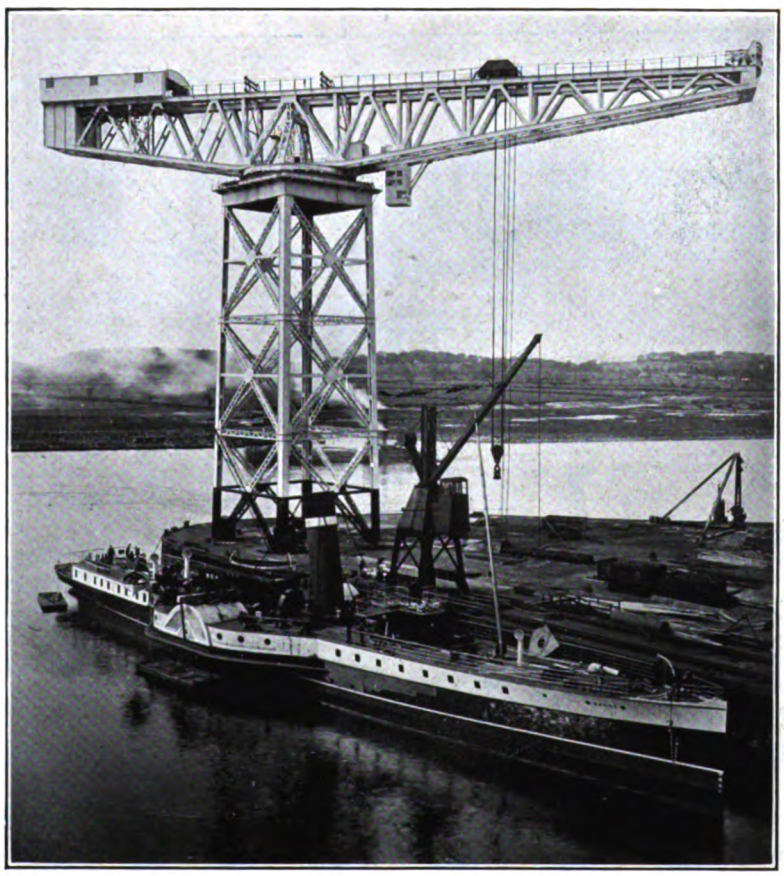

FIG. 9.—150-TON CRANE, BY SIR WM. ARROL & CO. AND MESSRS. STOTHERT & PITT.

In the building of the Cunard liner "Lusitania" two large electric derricks, made by Sir William Arrol & Co., were used. They were designed to lift loads up to 5 tons in weight to a height of 120 ft. from the ground level, with a working radius of 35 ft. from the centre of the mast, and with a jib slewing through 180 deg. The mast is made in the form of an open lattice-work column of square section, with four corner angles, well braced together. Four guys are attached to the top of the mast, and one underneath the jib. A platform for the electrical gear is arranged at a height of 95 ft. above the ground, and from this point is carried the jib which is rectangular in section. The jib is set at an angle of 45 deg., and at the outer end there is fixed the usual pulley for the lifting rope. This rope passes over a deflecting pulley at the base of the jib, and thence through the centre pin to the winch located on the ground level. The lifting motor, of 30 B.H.P., is arranged for two speeds of lifting—90 ft. per minute and 210 ft. per minute, the former being for the full load of 5 tons. The slewing motor is placed on the working platform.

* *Trans* Inst. N.A., March 21, 1907.

A new type of travelling jib crane, intended to take the place of derricks, overhead cranes and ropeways, has been designed and constructed by the Babcock & Wilcox Co. for service in the Tees Dockyard, Middlesbrough. The crane is of the derricking type, with a jib 60 ft. long, balanced by means of a travelling weight and compensating gear in the column. It is mounted on a carriage 60 ft. high, so designed that it will work on a track of 22 ft. gauge, laid between the berths with sufficient clearance to permit travelling jib cranes or railway trucks to pass underneath. By means of the derricking gear the jib can be used on a long or short radius, either above or below the horizontal line, which admits of the jib being lowered to within a few feet of the position where the load is to be landed. Dangerous swinging of the load is thus avoided. Separate motors are provided for lifting, derricking, slewing and travelling, and these are controlled from a cabin on the platform.

FITTING-OUT BASIN CRANES.

From a careful study of the arrangement of existing shipyards it would appear that the form of crane best suited for placing in position the heavy machinery which enters into the construction of a ship is a fixed revolving tower crane of variable radius, which, for want of a better name, is known briefly as a hammer crane on account of the hammer-like appearance of the double-armed outrigger and crane post or tower.

The ideal position for a hammer crane is on a mole or tongue of land, because in this position two ships can be fitted out at once, thus obviating the necessity for moving the ships to and from the crane.

British and German built cranes of this type are shown in Figs. 9 and 10. It will be perceived that in the German design, Fig. 10, the double cantilever jib is connected to a structural steel post which forms the central axis of a pyramidal framework. The post rests on a roller footstep bearing, and near the upper extremity it bears against a pressure ring formed in the caps of the tower. In the British design, Fig. 9, the post is dispensed with, and the jib is carried on a live ring supported by box girders fitted between the legs of the tower.

The mechanisms for lifting the load and for traversing the trolley are usually arranged on the balancing arm of the outrigger, so as to minimise the weight of the trolley and of the jib, and the weight of the machinery assists the moment of the balance weight. In some cases, however, the mechanism is arranged entirely upon the trolley, or partly upon the trolley and partly on the balancing arm of the outrigger.

An objection to the ordinary type of hammer crane is that the cantilever arm in rotating may foul the masts of vessels which are being fitted out, or prevent masts higher than the crane itself being placed in position. Whether this objection will limit the use of these cranes in the future cannot be foretold, but it has been overcome in an ingenious manner in a 150-ton crane constructed by the Benrather Maschinenfabrik A.-G. for Messrs. J. C. Tecklenborg's Shipyard, Bremerhaven.

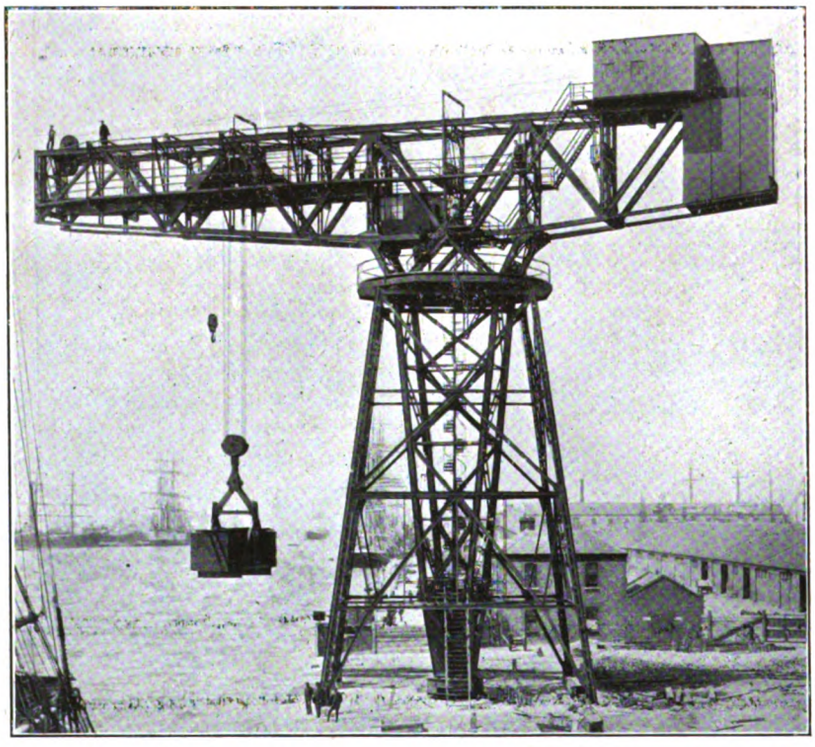

FIG. 10.—100-TON CRANE, BY THE M.A.N. CO.

In this crane the main crab runs between the main girders of the jib, and the machinery house is placed between the girders at the tail end. A slewing jib crane of 20 tons capacity travels on a track laid on the upper flanges along the entire length of the cantilever from back to front, namely, 220 ft. 6 in. The maximum radius of the main block is 125 ft. with a load of 65 tons, and the maximum radius of the travelling jib crane is 156 ft. with a load of 5 tons, and 144 ft. with a load of 20 tons.

General arrangement drawings are given in Fig. 11 of a giant crane of 160 tons capacity, designed by Messrs. Cowans, Sheldon & Co. (Ltd.), and installed at H.M. Dockyard, Devonport. The crane differs from other cranes of this type in several respects. To meet Admiralty requirements the lifting mechanism is composed of two complete sets of 80-ton gear, either of which may be operated separately, or the two may be used together. Moreover, the operator's cabin is not mounted directly in the jib, but is fixed 25 ft. above the quay level on a lattice frame which rotates with the jib.

From the drawings it will be seen that the crane consists of a strongly-braced tower 109 ft. high, composed of four columns 2 ft. 6 in. square set at 46 ft. centres apart, provided with a roller bearing 46 ft. diameter on the top for carrying the two cantilever jib girders. These girders have a total length of 220 ft., and the depth at the centre is 28 ft. They are fixed at 20 ft. centres apart, and upon the top flanges of each two sets of rails are laid. There are 72 wrought steel rollers 12 in. in diameter in the live ring, and the forged steel centre pin is 18 in. in diameter.

The lifting and traversing mechanism is enclosed in a steel-plated house fixed at the tail end of the jib, and assists in counterbalancing the crane. A ballast box is built in between the girders, and filled with 160 tons of stone ballast. A 12-ton travelling crane, with electrically-driven lifting gear, is mounted over the machinery, and in order to lower any of the machinery to the ground level the crane can be run out at the back end of the house. The slewing gear, in duplicate, is enclosed in a steel house in the jib at the centre of the crane, and lifting tackle is provided for dismantling and repairs.

Loads of 160 tons in weight can be lifted at 95 ft. radius, 80 tons at 105 ft. radius and 30 tons at 128 ft. radius. The several motions are worked at the following speeds :—

Main lift	160 tons,	two blocks,	at	6 ft.	per minute.
	80 tons,	one block	,,	6 ft.	,,
	15 tons	,,	,,	30 ft.	,,
Light lift	30 tons	,,	,,	20 ft.	,,
	7½ tons	,,	,,	75 ft.	,,
Traversing	160 tons	,,	,,	30 ft.	,,
	80 tons	,,	,,	60 ft.	,,
Slewing	160 tons,	one revolution	in	8 minutes.	
	80 tons	,,	,,	6	,,
	No load	,,	,,	6	,,

The total height of lift is 170 ft.—viz., 120 ft. above and 50 ft. below quay level. Each main block is carried on eight

parts of extra special flexible plough steel wire rope 4¾ in. circumference, and the free ends coil on to grooved barrels 75 in. diameter and 10 ft. long, which are driven through treble reduction steel machine-cut gears. The light block depends from four falls of rope, 4¼ in. circumference, reeved double, the two parts coiling right and left-handedly on to a barrel 39 in. diameter. Electro-mechanical and Weston automatic mechanical brakes are fitted on each lifting gear. It is inter-

esting to note that the brakes, change-speed gears and motors for the main and auxiliary lifting mechanisms are alike and interchangeable.

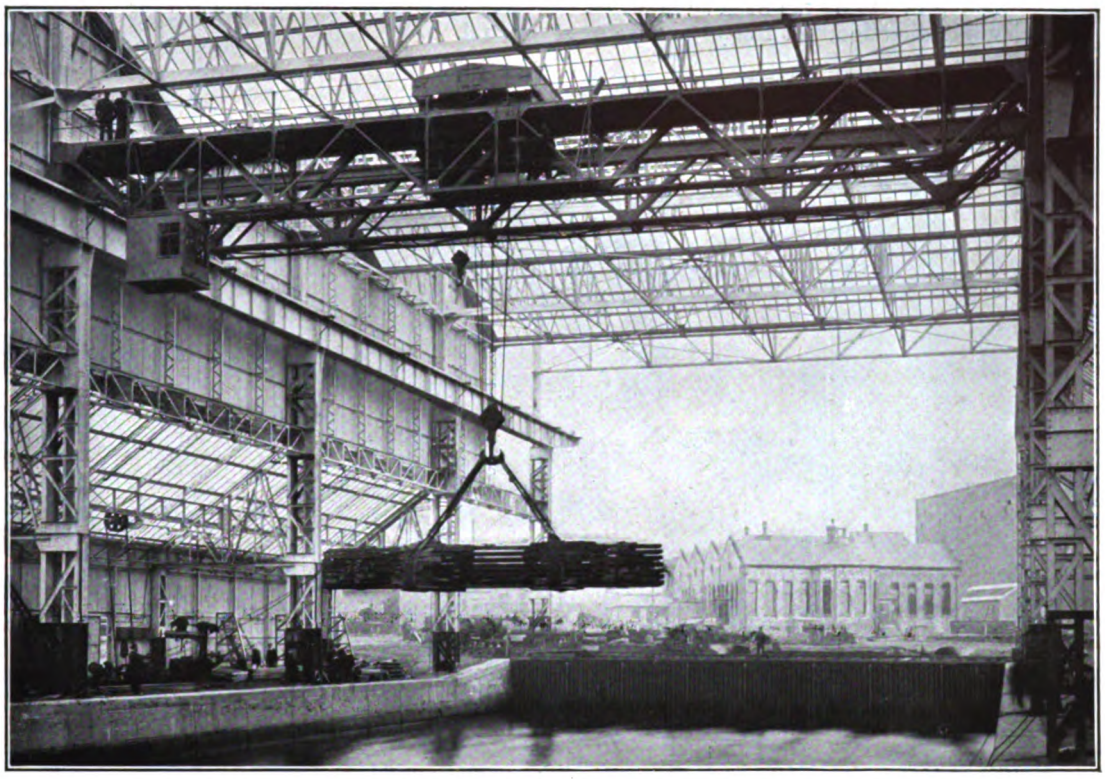

FIG. 12.—COVERED-IN FITTING-OUT BASIN AT YARROW'S SHIPYARD.

The various motions are worked by means of totally-enclosed 440-volt series-wound continuous-current motors (one hour rating with a 70°F. temperature rise) of the following sizes :—

Main lifting	2 motors, each	60	B.H.P.	at 550	revs.	per min.
Auxiliary lifting	1 motor	60	,,	550	,,	,,
Slewing	2 motors	60	,,	550	,,	,,
Traversing.....	1 motor	30	,,	580	,,	,,
Overhead crane	1 motor	10	,,	630	,,	,,

The main lifting motors are operated by a three-drum controller, the right and left-hand drums of which control the corresponding sets of lifting mechanism in the usual way. The third drum is used when it is required to work the two sets of gear together, and an adjustable field rheostat is provided to ensure the two motors running at the same speed irrespective of the loads upon them.

The crane was tested with a load of 240 tons at a radius of 95 ft., and no lateral deflection or vibration was noticed during the whole of the tests.

The many cranes of this kind designed, constructed and erected by Sir Wm. Arrol & Co., the Appleby Crane Co., and Cowans, Sheldon & Co. bear eloquent testimony to the skill of British engineers, and serve well to show that designers at home are in no way behind their Continental brethren.

Covered-in basins served by overhead travelling cranes are used to some extent in America, and to a less extent in this country and on the Continent. An excellent example is to be found at Messrs. Yarrow's new shipyard at Scotstoun, and Fig. 12 serves to give a general idea of the arrangements of the basin. The gantry—323 ft. in length—is continued 20 ft. outside the building over a railway track to enable the crane to take the load from trucks at the head of the basin. The crane, designed and constructed by the Appleby Crane & Transporter Co., is of 93 ft. span, and is of 50 tons capacity with an auxiliary hoist of 10 tons. Motors of 50 B.H.P. and 30 B.H.P. respectively are used for the main and auxiliary lifting mechanisms, and the travelling and traversing motors are capable of developing 10 B.H.P. and 15 B.H.P. for one hour with a temperature rise not exceeding 90°F. Under full load the speeds are: Main lifting 10 ft. per min., auxiliary lifting 30 ft. per min., travelling 250 ft. per min., and traversing 80 ft. per min.

From the foregoing it will be apparent that the electrically-driven crane lends itself in an admirable manner to the many and varied requirements of shipbuilders. The "new" motive power has enabled man to be of greater service to his fellow men, but assuredly one of the greatest engineering triumphs of modern times is the remarkable progress made in one of the oldest arts practised by man—the art of handling material.

The "Clyde" Electric Capstan

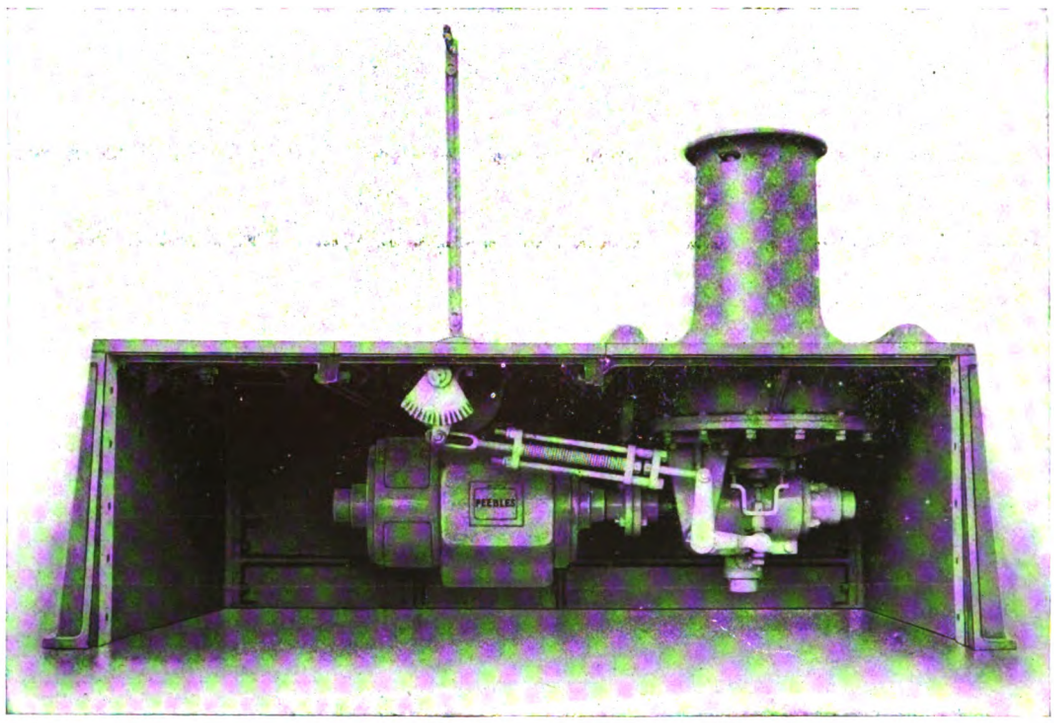
Electric capstans, although admittedly more economical than their hydraulic rivals, have always been regarded with some suspicion on account of their alleged unreliability and proneness to breakdown, and many engineers have frequently adopted the latter type, preferring to accept its many inferior qualities in order to secure the more robust construction. We are, therefore, pleased to have an opportunity of illustrating a new type of electric capstan which marks decided progress in the construction of this class of machinery. This capstan has been patented by Mr. Walter Dixon, consulting electrical engineer to the Clyde Navigation Trustees, and Mr. George H. Baxter, the chief mechanical engineer to that authority; it is known as the "Clyde" type, and the general arrangement of its working parts is shown in the illustration. In addition to the usual wear and tear upon the gearing the heads of hydraulic and ordinary electric capstans are subjected to considerable grooving, due to the action of the hemp ropes ordinarily employed upon them, and the ropes themselves, owing to their very short life, are responsible for a substantial annual expenditure. Where capstans are regularly dealing with traffic incidental to docks and similar places, it would appear that the cost for ropes per capstan per annum may be anything from £10 to £20, a fair average being £15. The "Clyde" capstan, while possessing in a marked degree the increased

Digitized by Google

efficiency and other well-known advantages of the electric capstan, claims to have further increased its field of usefulness by eliminating the abnormal expenditure in ropes. This is attained by means of the special features embodied in its construction, primarily consisting in having the head so arranged that it is fixed in the hauling direction, but free to revolve in the opposite direction, thus rendering it possible to use a fixed wire rope in place of the loose hemp rope, and reducing the cost of ropes to something under £1 per capstan per annum.

With regard to power consumption, it has been found that the employment of the "Clyde" capstan reduces the amount of current consumed by not less than 25 per cent., and, what is an equally important matter, the maximum demand from the power station by, perhaps, 50 per cent. These important points are well worth the serious consideration of all interested in the installation of capstans.

The "Clyde" capstan can be controlled either by one handle, or by one handle and a foot pedal, and in either case no attention is required for the rope, which, as stated above, is fixed permanently to the capstan head. The capstan head and box containing the electrical equipment is of well-ribbed cast iron and the box is arranged for letting in flush with the ground.



THE "CLYDE" ELECTRIC CAPSTAN.

Although a number of these capstans have been in use for some years, they are only now, after their reliability has been amply proved, being actively put on the market. They are manufactured by Messrs. Bruce Peebles & Co., Edinburgh, who are one of the firms at present licensed. About 100 capstans have been installed, or are in course of construction, and in practically all instances, we believe, repeat orders have followed their installation, thus demonstrating that they appear to fill a long-felt want, and confirming the claim that the difficulties and troubles hitherto experienced in electric capstans have been overcome.

Oerlikon Gearing for Marine Work.

Worm gearing, as is well known, is one of the most efficient means of reducing the speed of a motor. It takes up less room than does other gearing, runs more silently and is more certain in operation. These advantages are of great importance when the ratio of reduction is above 1 to 10, that is, when an ordinary gear with a single pair of toothed wheels is not sufficient. In this case, also, the small expenditure of energy must be added to the advantages detailed above. Greater efficiency is obtained from worm gearing than with toothed gear wheels, and it can further be very efficiently applied in connection with electric motors which generally run at high speeds. Up to the present it has not found such an extended application as had been hoped, taking into account the rapid extension of the electric drive, a state of things which is due to an erroneous idea that such gearing has only a low efficiency and wears out very soon.

To the existence of such prejudices books on mechanics have contributed not a little, though the success obtained by this gearing in certain directions, especially on travelling cranes and machine tools, is so much in its favour that it is now finding an application in several new directions. The Maschinenfabrik Oerlikon, who have a London branch, were one of the first firms to undertake the manufacture of worm gearing, and they have, since 1890, contributed greatly to the advance of this class of machinery.

In constructing such gearing great care must be taken, and the Maschinenfabrik Oerlikon have laid down a special set of tools for this purpose. The gearings made by them are constructed in six different sizes, and each part of any one set of gearing is interchangeable. In the new type the pressure of the teeth along the shaft of the worm is no longer taken up as it used to be by two bearings, but by one alone, which takes up the axial pressure in two directions. Besides, the bearing is no longer placed in the same compartment as the worm and worm wheel, but is separated from it. This arrangement has the great advantage of preventing damage to any part of the gear should it carry away. The worm is now made of cast

Digitized by Google

steel of the first quality, and is highly polished, the worm wheels being of cast iron with a capping of phosphor bronze. In the newest type of Oerlikon gearing, the worm is placed above the worm wheel, an arrangement which has many advantages, both from the designing and operating point of view. The whole of the gearing is contained in a cast-iron case in which is placed the lubricant for the gearing.

As regards the application of this type of gearing, it is now employed for a number of widely different purposes. One of the most extended directions for which it is used is in connection with the electric motor on such intermittent work as cranes, hoists, rolling mills and other similar applications. Another direction which is not less extended, but is rather more of a continuous character, is the driving of machine tools and machines for printing textiles. Lastly, the worm gearing can be successfully employed on quite continuous operations, such as driving pumps or air compressors and other similar work. The illustrations herewith show this gearing more specially adapted to marine work. Fig. 1 is a special set of worm gears fitted with brakes, which have been designed for use in the barbettes of certain battleships in the Italian Navy. Fig. 3 shows an electrically-driven horizontal double winch

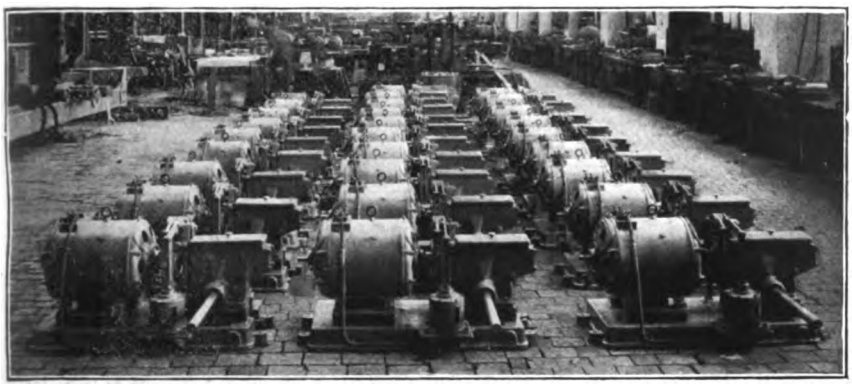


FIG. 1.—A SET OF WORM GEARS DESIGNED FOR THE ITALIAN NAVY.

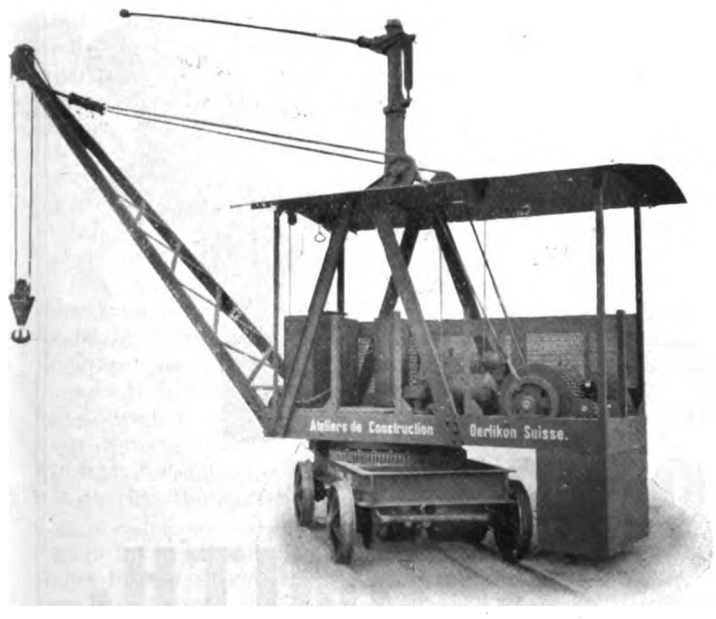

FIG. 2.—ELECTRICALLY-DRIVEN 5-TON WHARF CRANE.

fitted with worm gearing and electric brake, while Fig. 2 shows an electrically-driven 5-ton wharf crane.

The application of worm gearing is limited in one direction by the ratio of reduction which must not be less than 1 to 6 or 1 to 7, and in the other direction by the pressure between the teeth. The most favourable ratios of reduction are between 1 to 10 and 1 to 20 and for large gearings these figures cannot be very much extended without considerable inconvenience. Under favourable conditions worm gearing may be employed for powers up to 100 H.P. For large powers and small speeds it is recommended that the gearing should be used in connection with a toothed wheel in order to ensure high efficiency and prevent wearing out. In general, worm gearing is constructed for as high an efficiency as possible, especially when large

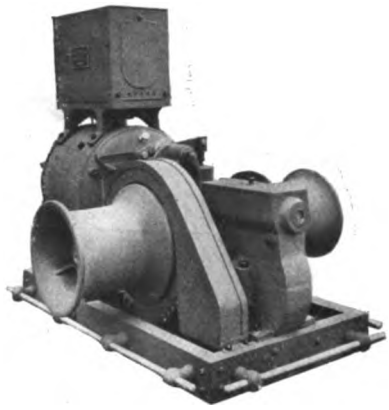

FIG. 3.—ELECTRICALLY-DRIVEN DOUBLE WINCH WITH AN ELECTRIC BRAKE AND WORM GEARING.

powers are being transmitted. By a judicious choice of the dimensions and careful manufacturing, the Oerlikon Company consider that worm gearing can be made to work under the most severe conditions. On the other hand, for small powers and low speeds, the efficiency plays a less important part than simplicity and cheapness of the apparatus. In such cases a lower efficiency may be allowed in order that the ratio of reduction may be increased.

The Coaling of Ships.

An arrangement of the greatest importance for sea-going folk in general has recently been placed on the market by the Felten & Guilleaume Lahmeyerwerke, of Frankfort. This enables coaling at sea to be easily effected.

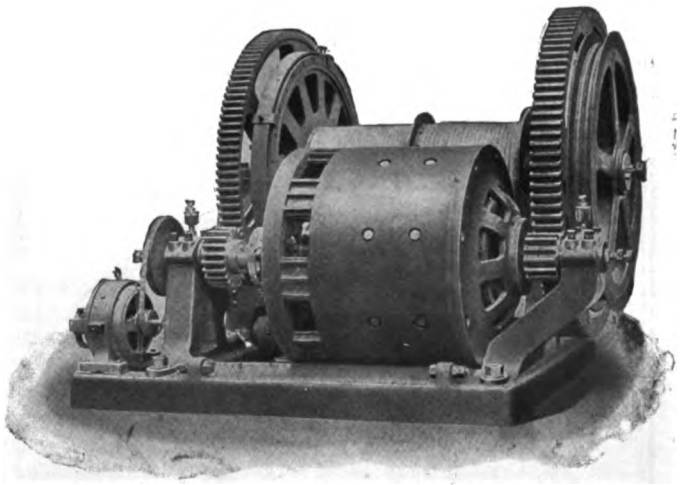

FIG. 1.—HOISTING GEAR FOR COALING SHIPS.

The system, which is shown diagrammatically in Fig. 2, is based on the principle of continually transporting small loads from ship to ship on an endless rope stretched between them. To this rope the loads are affixed by elastic slings, and are drawn direct from the collier to the deck of the battleship.

The slings, contrary to the usual hook arrangement, are enabled by their flexibility to be brought very quickly to any desired level, and are carried to several discharging places which are placed, so to speak, in series. This arrangement is not, it is

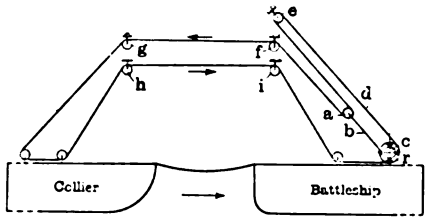

FIG. 2.

said, employed in any other system, and on it rests the great efficiency of the apparatus. The "uncoaling places," which can be placed in any desired position depending on the hatch, consist of a simple, rigid cone, through which the wire passes, but which is fitted with a slit so that the loads placed on at the other stations pass freely by it. The sling is placed on this cone, and, when the load is ready, is drawn on to the running cord. On the deck of the warship the load is cut away by a knife placed under the wire.

A characteristic of the system is the electrical driving and tension system used in connection with the endless rope. As shown in Fig. 2, the wire is driven by a motor, and is kept at a constant tension. In this way the energy consumed is reduced to a minimum. Fig. 1 shows the gear used with this arrangement. In the newest form gearing is entirely avoided, the wire pulley being directly driven from the magnet, and the tension drum directly from the armature. This combined tension and driving arrangement makes up a very simple equipment which, it is claimed, is entirely free from disadvantages. Many tests have been carried out with the apparatus on both sea and land with uniformly satisfactory results.

Switchboards on Warships.

BY A. G. COLLIS.

Summary.—The author summarises the former and present specifications of switchboards for warships, and criticises the lack of uniformity in design. It is essential that manufacturers entering this field of work should specialise. It is also highly desirable, he urges, that parts of gear should be interchangeable even if made by different makers.

Political feeling is centred on the question of the efficiency of our Fleet, comparison being made numerically relative to the "Two-Power" standard, from which calculation is deduced whether we are in a position to prevent an invasion or to lose our present supremacy at sea; and so it appears that the effectiveness of our Navy is fundamentally based on the number of "Dreadnoughts" we have at our disposal, there being a total disregard of other measures adopted to protect and maintain our commerce.

Such comparisons are not only erroneous, but misleading, inasmuch as the determining factors of our effectiveness are not only to be found in numbers but in the efficiency and application of the methods as well as the results obtained by the engineering architects in the production of a war vessel. When all details are considered, apart from the electrical or mechanical features, such as "value of fighting force," "speed and control of the boats," "the performance of exceptional tactics," "skill of superior officers," "position of naval bases," "precision of gun fire," "efficiency of the marine," &c., there is no doubt that this country will shortly be in need of more vessels in the fighting line if we wish to keep up the developments of these machines in distinct ratio to other naval forces.

It is known that the control departments of other naval powers are endeavouring to approach standardisation and simplicity without destroying efficiency, in order that replacement and assembly of gear can be made in the shortest possible time. It is therefore necessary that the engineering section of the public should direct their attention to this important portion of the vessel, so that we, too, shall be in the advance line of development in this direction. There is very little doubt that the modern electrical equipment of a battleship is complicated by the introduction of variable designs which could be simplified with equally efficient results, although it must be understood that in electrical control design we are in advance of other nations through the instrumentality of Mr. C. H. Woodington.

The standard battleship switchboard of former times consisted of an iron or steel channel frame of substantial construction, the metal testing to a tensile stress of 25·30 tons per square inch. 4 in., by 1½ in. in section, and was of such a form as to admit of all the power circuits on one side and the lighting circuits on the other, the generator control gear being in the centre. The number of circuits is varied to meet requirements, the average being eight power circuits, 13 lighting circuits, the board then having an overall length of 17 ft. 9 in. by 8 ft. 3 in. in height. There were four generator circuits, each being controlled by a maximum and reverse current circuit-breaker, interlocked with an equaliser switch, ammeter and voltmeter of the edgewise type and rheostats. The power circuits were fitted with D.P. circuit-breakers only, the lighting circuits with D. P. switches and fuses, the 'bus bars and all live gear being insulated from the frame by mica or micanite, ambroin shields being provided between crossings. Expansion joints were used as occasion demanded.

The circuit-breakers were of special design and for machines were of the maximum and reverse type, and, if possible, fitted with time limit attachment, but must be interlocked with equaliser switch. The overload has a range of adjustment for the excess current between 50 per cent. and 100 per cent., and for the reverse current 10 per cent. to 30 per cent. of the normal load current. With reference to time limit attachment, if it is possible to fit same on the circuit-breaker the rupture should be delayed from 5 to 10 seconds. The circuit-breaker must have a non-closing feature, which prevents the operator closing the circuit when an excess or a reverse current exists. The contacts are to be protected first by auxiliary metal contacts and secondly by carbon breaks upon which the arc is broken. These contacts must be easily replaceable. The breaker is operated by a single handle, and stress is brought to bear upon the point that the circuit-breaker must not open accidentally by vibration or shocks. The insulation is mica or micanite throughout, and the working parts are fitted on a strong channel frame or steel plate. The weight is as light as possible without reducing efficiency, strength and reliability.

The Admiralty favour a uralite partition fixed between the poles if circuit-breakers are arranged in parallel, so as to prevent arcing across. Also they like some guard whereby an operator cannot come into contact with the two poles when operating. The series coils are preferably made of solid drawn H.C. copper, connections being taken therefrom by cast gun-metal pillars. Shunt coils are wound with D.S.C. copper wire, and are protected by brass shields, the wire connections being carried in beaded tubing.

The equaliser switch is designed for the same current density as the circuit-breaker. The switch is coupled to the breaker in such a manner as to prevent the latter being closed

Digitized by Google

while the former remains open, and also to cause the circuit-breaker to release before the equalizer switch can be opened. The tripping gear of the circuit-breaker is actuated entirely separately on either or both poles.

The total cost of this board, including breakers is in the neighbourhood of £1,000, and it is very efficient. The "Scout Class" board is of a similar nature with the exception that the conditions are not so severe, and it is of much smaller dimensions. D.P. maximum circuit-breakers, with ammeter and voltmeter are used for the generators, and D.P. switches and fuses for, say, 10 circuits, the switch contacts being directly on the 'bus bars with front connections.

At this time, considering that some of the Japanese boats were being built in this country, one would have thought that the Japanese would have followed English practice. This, however, was not so. The switchboard base in their case was slate, the circuit switches being of the multiway type. This, of course, is bad practice, as a concussion or severe shock in action would destroy the equipment; and, further, owing to the small space available, and the number of small sections which comprise the board, in order to get it down the hold, the strength of the base was materially reduced by the number of holes for the fixing of the gear, so much so that in erecting one board in particular the base cracked and had to be strengthened by stays in fitting up. Slate for mounting on marine work is bad practice. Its electrical features as well as its mechanical strength are inconsistent with the duties to be performed.

The Admiralty are exceptionally precise as to the constructive details of the board, and in the course of time many details are redesigned to meet conditions found by experience, and it is remarkable that shipbuilders do not follow even the principal features of their development, especially with large liners and subsidised boats. In some of these vessels one notices complicated details, such as relays and delicate mechanism. Yet it is obvious that, in case of war, these vessels would play a very important part, not only in protecting commerce, but in supplying the needs of the country. A sharp and decisive shot would settle for good the functions of this control, slate being the base of the mountings.

There is no necessity for a feeder to be protected by time element overload, and, in addition, from instantaneous short, as in the case referred to above. This may be correct for central stations and land distribution supply, as the conditions are difficult.

In another group of large liners there is another variety of design, in one case D.P. switches and enclosed type fuses protecting the machines. In yet another case the generators are protected by D.P. circuit-breakers of the maximum type. The fuses of the various boats are, "porcelain enclosed type," "open type with asbestos tubes," "patent semi-enclosed type," the circuit switches being of the change-over four-way type interlocked with a S.P. switch, so that each outgoing circuit could be placed on any set of bars. There appeared to be no provision for parallelling the generators. It is obvious that, consistent with the property of fuses, should a short-circuit occur on the outgoing feeder, and the circuit-breakers protecting the generators be instantaneous, the plant would be shut down while the fuse continued to hold; and on the other hand, in the case where the generators were protected by fuses, that the generator fuse may blow before the circuit is interrupted. A further peculiarity with these transmissions was the fact that circuit-breakers were supplied on the motor side. It is not a question of criticism as to what form of switchboard is the best, but these facts show a lack of uniformity. The present Admiralty board is totally different from the one described above, and is generally now of the electrical solenoid type, each circuit being controlled by an auxiliary circuit.

The solenoid switch as now designed is very difficult for manufacturers to make, and the specification is exceptionally stringent. It may be quite necessary, but here again is an entirely different departure from the board first described, and if it is admitted that the new design is essential so much more so are the remarks above emphasised. It is agreed that the conditions at sea are unique, and therefore the usual practice in land transmissions is not applicable in this direction. Therefore is it necessary that such manufacturers as are desirous of entering this special field should specialise and apply individual departments to this manufacture. Many firms have suffered severe losses by not realising this fact. The Admiralty are very desirous to meet any manufacturer's standard. The standards submitted, however, in most cases show that the principles of construction adopted are a negative quantity to a ship's equipment; hence definite laws and rigid specifications are submitted to tenderers, which, from a manufacturer's point of view, are extreme, and the manufacturer either submits a tender without any endeavour to secure the work, or, if he does not specialise in this class of material, he submits a price that will result, almost in every case, in a loss. Although Admiralty gear is special, provided proper organisation is made for its manufacture, the establishment charges necessary are considerably lower than the general establishment charges of a large number of firms.

High-tension switchgear entails considerably more dead charges, and if it is decided to develop all the designs of electrical control used in a ship, such repetition designs as the watertight switch, plug and bulkhead fittings, &c. (when once the jigs are made) will considerably reduce the estimated dead charges on such designs as are not produced in machine manner. The experience of Admiralty gear is the most abstruse on the foundry side, as most of the designs do not lend themselves to machine moulding, and are even difficult to cast on brass founders' sand moulds as artificial leavings and cores are necessary. Small details, such as turn buttons, &c., come out cheaper in casting in sprays on sand beds than on machine moulds.

In German designs, although they have the advantage in sand and casting, using practically no facing whatever, machine moulds are employed on day work in preference to the practice of piece work in some of the foundries I have visited. The design of their gear, however, is such that evidently it is the cheapest method, and it is admitted that their standardisation is more in advance, not possibly in design, but in uniformity of design, the component parts of the gear being as far as possible interchangeable with all apparatus. For instance, the terminal on the distribution box being, according to its size, the same throughout as the other distributional apparatus in the ship. Their switchboard design is practically identical on all classes of boats in outsea manœuvres.

It must be expected that the gear controlling, say, a gun boat and battleship cannot be identical, but its component parts could be interchangeable, so as to be easy of production, and so that gear put out of action could be easily replaced.

We, on the other hand, taking as an example, the circuit-breakers described above, make a contract over a period with, say, two companies who have successfully passed the tests, and these circuit-breakers may be totally different in design, and not interchangeable with the other company's manufactures. This does not only apply to circuit-breakers, but also to starting gear, instruments, &c., so it will be seen that a heavy variable stock has to be kept for replacements, it being understood that some portions of the design are made to gauge. On the other hand, other naval powers approach this matter as far as possible differently, the design being settled by those in command, and must be rigidly adhered to. This is the case with the British Admiralty concerning the manufacture of distribution boxes, connecting boxes, plugs, switches, &c., but the regulations do not apply over the whole material. The system of balancing is not used by large foreign admiralties, and their transmissions are very similar to the principle used on the King Edward VII. class. Ambroin, together with mica or micanite of a definite quality, appears to be used almost exclusively by most naval powers; asbestos or asbestos slate are considered unsatisfactory for sea conditions, and it is peculiar that these dielectrics have not been replaced by other material, thus leaving the field entirely open to patentees. On systems used on land this material is not so essential as others, such as uacolite or pegamoid, the latter being noted for resistivity to breakdown under high voltage tests.

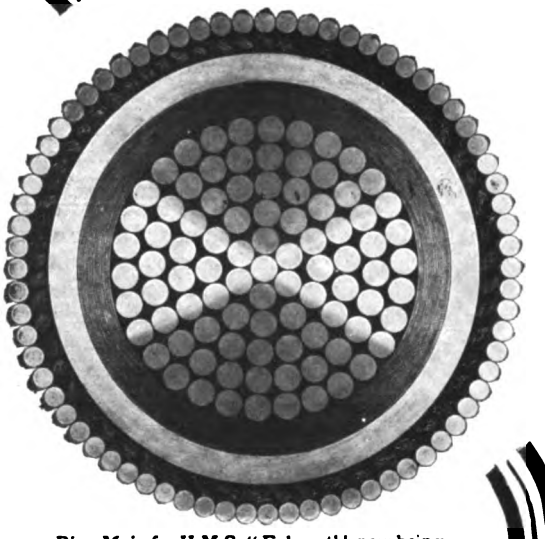
HENLEY'S CABLES

— FOR —

SHIPS, WHARVES AND DOCKS.



Ring Main for H.M.S. "Falmouth' now being built by Messrs. William Breadmore & Co. at Dalmuir.

1½ sq. inch Conductor, paper insulated, sheathed and wire armoured.

All the materials used by us are rigidly tested, physically, analytically and electrically, before being allowed to form part of the construction of our cables. Only first quality materials are accepted and only the greatest care is exercised in manufacture. It pays us to do our work this way because we get no rejections, and we get satisfied customers and repeat orders. It will pay you to get HENLEY'S CABLES because you will get cables of long "life," highest efficiency, and the finest quality that can be made. We have never sacrificed the quality of our goods for the sake of cheapness.

We manufacture cables of every kind, and all accessories in connection with cables. If you have not got our lists you should write for them now. And see that your next enquiry is sent to us.

The connections on a boat of a foreign power are amalgamated. This is not a new idea, as it has been used in bonding tram rails, but it is evident that it is possible to amalgamate without deterioration. Amalgam would be vastly superior to our present methods for heavy currents, heat losses being of primary importance. Tests prove the advantage of amalgamated joints, except in regard to corrosion. In one test of copper contact surfaces, 36 sq. in., fixed with four heavy bolts, a contact loss of 0·00199 volt was encountered in carrying 1,800 amperes. When the amalgam was used the loss fell to 0·00058 volt. It is possible that at some future time amalgamated joints will be the standard order of specifications.

Regarding the voltage used on most battleships, a saving in expense without any degree of risk could be made by using higher voltages of, say, 500 volts, thus saving approximately £6,600 in cable costs, the insulation used being of such a character that no deterioration would result from sea air.

Too little attention is directed by electrical engineers to the mechanical construction of the gear on general lines, but it is particularly noticeable that the mechanical construction of switchgear used by the Admiralty is superior to that of gear used on land, and it is refreshing to note that the electrical staff of the Admiralty is considered the most efficient staff of all the naval powers.

Large Capacity Switchboards for Ship Work.

From an extremely modest piece of apparatus the ship switchboard has evolved until at the present time it ranks in capacity with the gears which are to be met with in a large land central station. Electricity supply on board ship is no longer confined to the lighting of the vessel. The bulk of the subsidiary power operations is now entrusted to electric motors, and consequently the service conditions are very similar to those which obtain on an ordinary distributing network. The switchgear must be arranged to give independent control to a number of generators and a large number of feeders. Where the electrical installation is carried out on such a scale as that introduced into vessels of the "Mauretania" type the switch-gear scheme must provide for duplicate 'bus bars and interconnecting gear so as to ensure absolute continuity of supply.

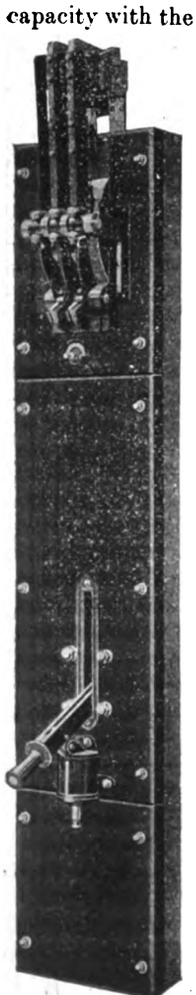

FIG. 1.—4,000-5,000 AMPERE CIRCUIT-BREAKER AS INSTALLED ON THE "MAURETANIA."

A typical example of switchgear of large capacity for ship work is that installed by Messrs. Ferranti Limited on the Cunard Company's ss. "Mauretania." This gear is divided into two portions, which are separated by a watertight bulkhead, and each section controls the energy supplied by two generators. An illustration of the complete gear showing the division between each portion is given in Fig. 2. Each half of the gear is placed in a separate engine room and one portion is practically a duplicate of the other. The equipment provides for two generator panels, three feeder panels, each fitted with four feeder circuits, making 12 feeders in all, and one coupler panel. These will be readily distinguished in the illustration. Each generator circuit is provided with a 4,000-ampere carbon breaker, which has an overload rating of 5,000 amperes for one hour. These breakers are separately operated by a lever handle which projects from the lower section of the panel in a position most convenient for closing. A time limit overload and reverse relay of Ferranti standard construction is fitted to each panel. The breakers themselves are placed on the top section of the panel, and each is provided with a substantial carbon break of the sliding type. The

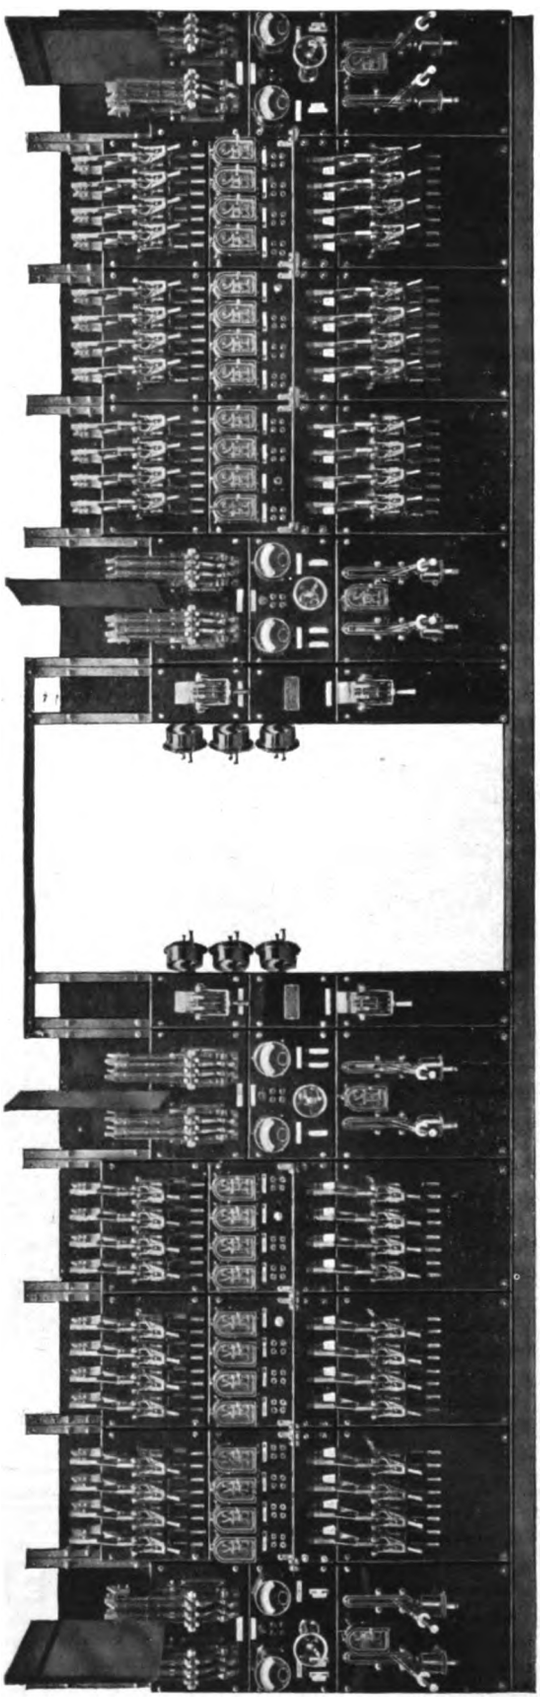

FIG. 2.—MAIN SWITCHBOARD ON THE SS. "MAURETANIA."

breaker is fitted with a free handle mechanism. Each of the feeder circuits is provided with a double-pole free handle carbon breaker, the positive and negative poles being arranged in a straight line down the board. The circuit protecting

Digitized by Google

devices include a shunt solenoid in conjunction with an overload time limit relay and a series solenoid. The latter is adjusted to a high-current value, so that it will not trip the breaker with less than 500 per cent. of its normal load. This method has been adopted to ensure that the distributor fuses in another part of the ship will come into operation before the breaker itself for all normal overloads. Anything in the nature of a short-circuit, however, will cause the series solenoid to trip the breaker immediately, whether the 'bus-bar voltage falls or remains near normal. The 'bus-bar voltage is only depended upon for tripping the breaker for ordinary overloads up to, say, 500 per cent. of normal, as under these circumstances the pressure is not materially reduced.

The 4,000-ampere circuit-breaker installed on the "Mauretania" is separately illustrated in Fig. 1. This illustration gives an admirable idea of the load which is now placed upon the generators installed in large modern vessels.

Ironclad Fused Switches.

The importance of ironclad switchgear for naval and marine electrical work is now recognised, and standard types have been developed for this class of work. A typical example of the modern ironclad fused switch is that made by Messrs. Berry,

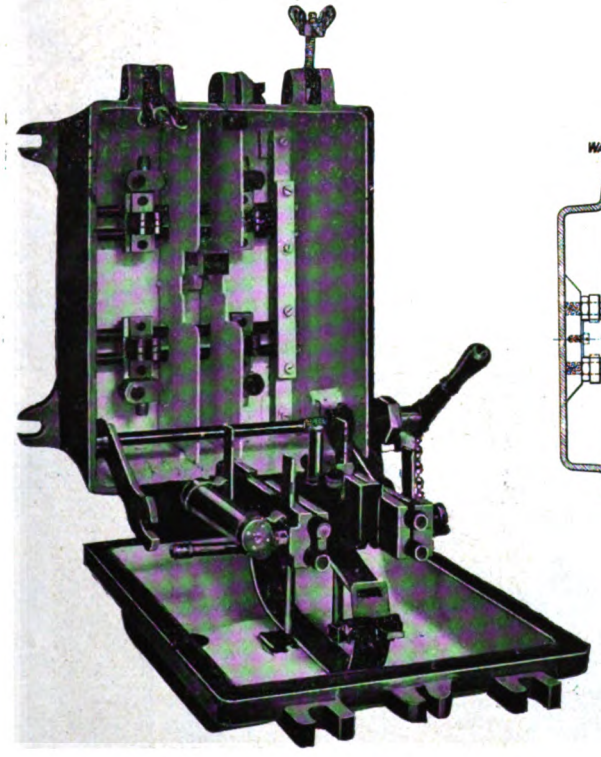

FIG. 1.—THE "DREADNOUGHT" FUSED SWITCH.

Skinner & Co., and appropriately termed the "Dreadnought." This switch which is shown in Fig. 1, is a development of the well-known push-and-pull pattern introduced by this firm some years ago, and installed in very large quantities for the control of electrical circuits in exposed situations, and more particularly in industrial services. The principal features of the switch are the method of insulation, quick make and break, breaking all four contacts simultaneously, and the interlocking of the cover with the switch mechanism, so that the circuit cannot be made with the switch cover open. In Figs. 2 and 3 we give line drawings of this switch, which indicate the substantial construction of the various parts and the attention which has been paid to the method of insulation. The fixed contacts are clamped to two parallel steel rods, each of which is heavily covered with mica. The same fitting which supports the contact clip is also used to hold the incoming sweating lug. The insulating bars are firmly secured to the bottom of the box by two saddles, one at each side, the saddles being held down by four screws.

The moving contacts are supported in a similar manner on insulated steel rods, and the mechanism is arranged to slide on two parallel guides which are firmly fixed in the lid of the box. A substantial bowspring fitted to this mechanism ensures quick make and break at all times. The spring is built up of three parts, and the longest of the three is attached to the lid of the box. This section is slotted at each end, and into the slots a shorter length of stiff flat spring is placed. The other ends of these two flat springs slip into slots in the body of the switch movement. These additional spring pieces have been introduced to admit of easy replacement in case of breakage. In the older pattern type of switch the bow spring was made in one piece only, and in case of failure it was troublesome to fix a new spring.

Projecting from each side of the switch carrier is a pin which engages with the forked ends of two levers, one at each side of

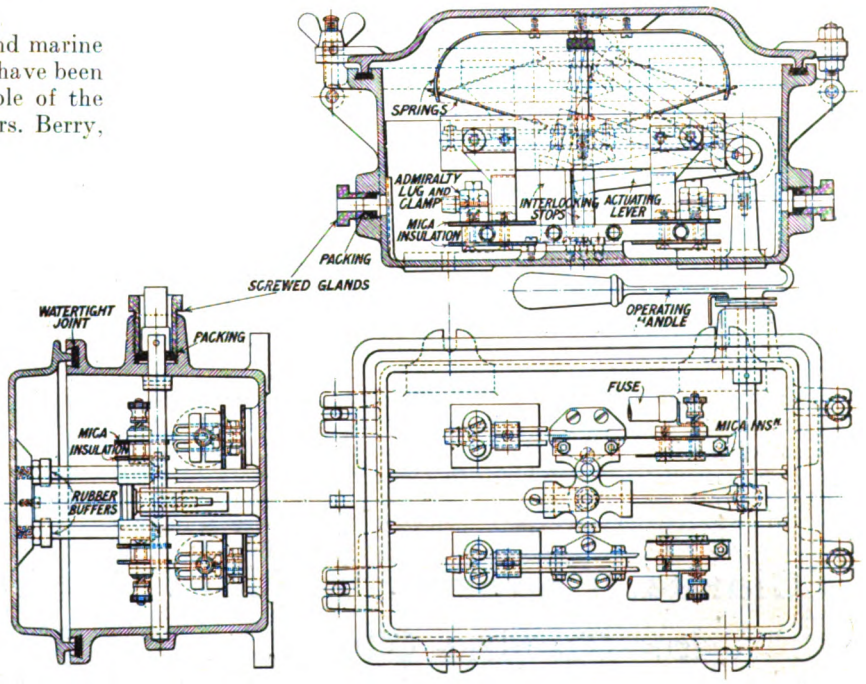

FIG. 2.—THE "INVINCIBLE" FUSED SWITCH, GAS AND WATERTIGHT 50 AMPERES, 600 VOLTS D.P.

the box. The other ends of these levers are secured to a shaft which projects at one side of the case through a stuffing box, and which terminates in a triangular-shaped boss, taking the standard Admiralty key. This construction will be clear on reference to the drawings. The switch movement is fitted with knife contacts, and each of these is bridged by an enclosed type cartridge fuse.

In the bottom of the box is a lug which acts as an internal lock, and prevents the cover being opened when the switch is on. This locking motion operates in the following manner. When closing the switch after shutting the cover the projecting pin on the switch carrier runs clear of the lug in the bottom of the case, and while the switch is in this position any attempt to open the lid is prevented by the fact that the pin will require a radial motion, which cannot possibly be given to it owing to the position of the switch.

The apparatus has been designed for and approved by the Admiralty. It is completely watertight, and is fitted with stuffing boxes for the incoming and outgoing cables. We understand that an insulation test showed practically infinity, and this speaks well for the type of insulation adopted.

Digitized by Google

The switch is made for pressures up to 600 volts and capacities up to 250 amperes.

We understand that during gun-fire tests the switch withstood the excessive vibration set up on these occasions, and it has been proved to be both dust and flame proof. It has also withstood a dead short-circuit test simultaneously across both poles at 600 volts without arcing to the cover. The replacement of the fuse is a simple matter, and we understand that only 30 seconds are required for this operation.

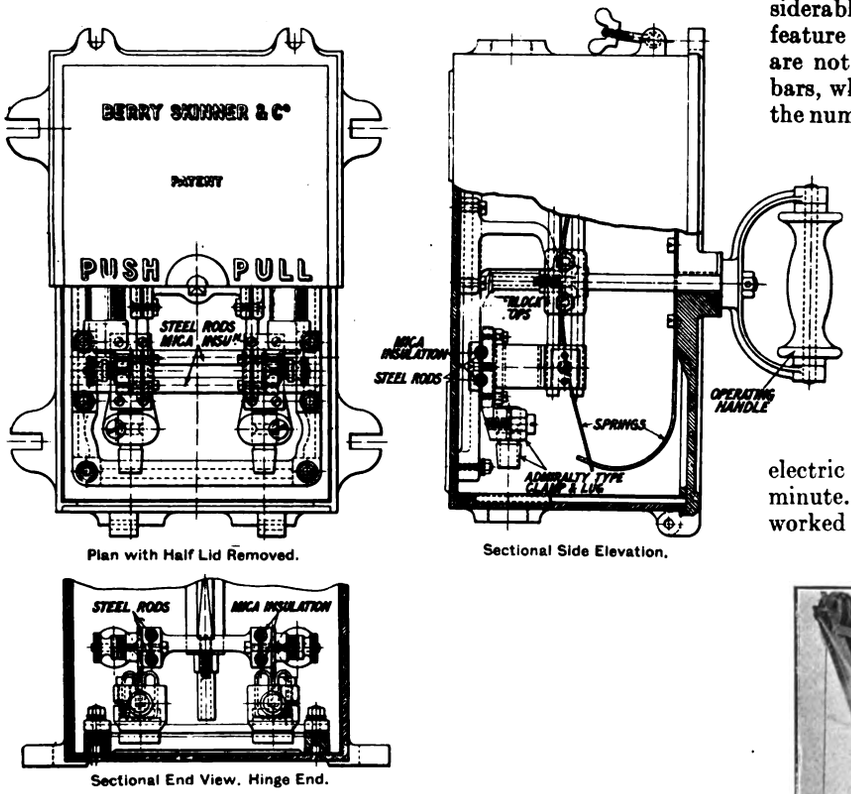

FIG. 3.—THE "DREADNOUGHT" FUSED SWITCH, 60-150 AMPS., 500 VOLTS.

Clarke, Chapman's Plant for Marine Work.

A firm who have for some years paid special attention to the design of electrical plant for marine work are Messrs. Clarke, Chapman & Co., of Gateshead. The accompanying illustrations and description give some idea of their activities in this direction.

To commence with the ship equipment, the two photographs of switchboards (Figs. 1 and 3) are representative of the class of board used on merchant vessels up to quite a considerable size. It will be noticed that the characteristic feature is that the dynamos, even where there are three sets, are not run in parallel, but are provided with separate 'bus bars, while each feeder circuit has a separate multi-way switch, the number of ways corresponding with the number of dynamos. Single-pole switches are used on the feeder circuits, though double-pole fuses are employed.

An interesting piece of apparatus is the steering gear made by Messrs. Clarke, Chapman. It consists of the ordinary screw type of gear modified for electric driving by fitting between it and the motor. This will be found described in a special article on Electric Steering Gear elsewhere in the present issue.

In connection with ship equipment mention may also be made of a small electric whip, which is found very useful for general purposes, such as lifting mails, stores or light baggage up to about 10 cwt., and of an electric jib crane, designed for lifting 30 cwt. at 120 ft. per minute. Four of these cranes were supplied all alike and worked very satisfactorily.

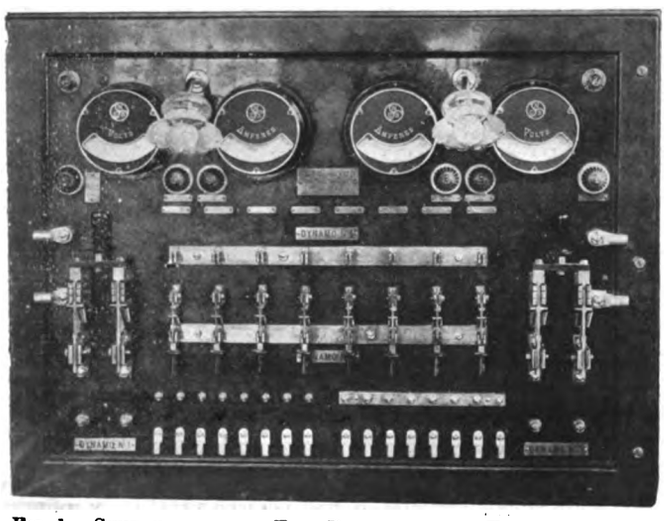

FIG. 1.—SWITCHBOARD FOR TWO DYNAMOS, WITH EIGHT CHANGE-OVER SWITCHES AND TWO DOUBLE-POLE DYNAMO MAIN SWITCHES.

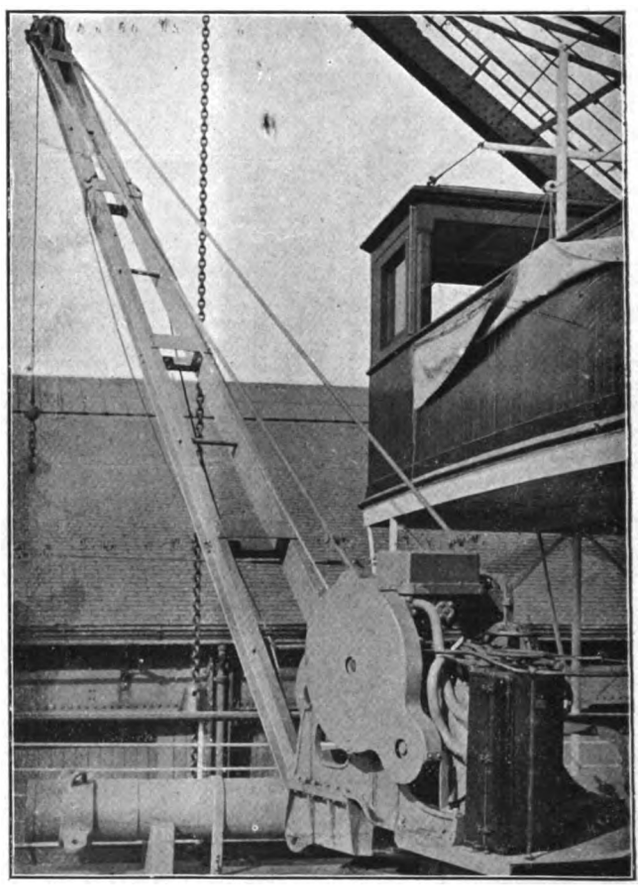

FIG. 2.—JIB CRANE FOR MARINE WORK.

Turning, now, to the question of shore equipment, three of the most useful pieces of apparatus are slipway haulage gear, dock capstans and a travelling jib crane. The first of these, shown in Fig. 2, needs but little explanation. It was designed to exert a pull of 30 tons by means of two chain cables, which are hauled in by means of cable lifters of the type used in ships' windlasses. The photograph makes the arrangement perfectly clear. The crane shown is fitted on a warehouse by the side of a dock and runs out over the vessel, the rails on which it runs being extended beyond the end of the shed.

Digitized by Google

The capstan, Fig. 4, is designed for a load of 8 tons and is provided with two speeds so that a higher speed can be obtained by changing the gear inside the box by means of one of the T handles shown projecting; the other T handle operates the controller, which is of the tramway type. The head is loose on its shaft, and driven by the two pins shown at the top, so that when these are withdrawn, the head can be operated by hand-bars inserted in the holes provided for them. When being worked by hand, the pawls at the base of the capstan are thrown in so as to engage with the rack at the top of the case.

The Wiring of Ships.

BY G. AUSTIN.

(Of Messrs. W. C. Martin & Co.)

Summary.—After enumerating the uses to which electricity is put on board ship and the various circuits that are desirable, the author discusses the question of the most suitable voltage, and the various systems of wiring that may be used—namely, single wiring, concentric and double wiring. The wires may be protected by wood casing, tubes, lead sheathing or armouring. Twin cable has much to recommend it. The insulation of wiring is rendered difficult by condensation and by the inevitable presence of salt. Careful erection is most important. Distribution may be on the system in which each light has its own fuse, or on that in which each group has a fuse; the latter appears to be sufficient. Owing to the special conditions, bell wires, as well as those for supply, should have good insulation. The article concludes with a reference to sundry applications.

There is perhaps no place where the use of electricity is so essential, and yet so easily applied, as on board ship. Essential, because cabins and other spaces are necessarily restricted in size, and, so far at least as lighting is concerned, there is no other illuminant available which does not vitiate the air. It is easily applied because in all steamships the steam-raising plant is already installed, and the addition of an electric generator or two, makes little or no difference to the engineering staff.

Before considering the subject of electric wiring in passenger and trading vessels, it may be well to enumerate some of the uses to which electricity is applied, and for which a system of cables or wires is required.

A passenger ship may be compared to a hotel fitted for the comfort and entertainment of a large number of guests, and the following are some of the services required:—

1. Lighting.
2. Wing fans or punkahs for wafting the air in saloons or lounges.
3. Cabin fans for circulating air in state-rooms.
4. Supply and exhaust fans for ventilating the accommodation generally, in conjunction with which may be installed apparatus for heating or cooling the air, or adding a small percentage of ozone to it.
5. Heaters for passenger cabins and lounges.
6. Cranes or winches for handling cargo, stores, mails and baggage.
7. Appliances in the kitchens, bakery, &c., such as for dough mixing, iceing, dish washing, knife cleaning, silver polishing, potato peeling, mincing, ham slicing, bread cutting, and revolving roasting spits. In addition to these there are hot-plates and other cooking appliances for use in pantries and bars, and food warmers for use in saloons or when serving refreshment on deck.
8. Laundry machinery and apparatus.
9. Curling iron heaters in cabins, and hairdresser's machinery and water heaters.
10. Wireless telegraphy.
11. Rudder indicators.
12. Watertight door indicators.

In addition to these, which require supply from the generating station, the following form a not unimportant addition to the wiring in a ship:—

13. Bells and telephones for passengers' use.
14. Bells and telephones for use of ship's staff.
15. Loud-speaking telephones for use on navigating bridges, machinery spaces, and lookouts.
16. Fire alarms, and fire signal bells.
17. Revolution indicators for showing on bridge, or other desirable place, the speed and direction of rotation of main engines.

There are many other uses to which electricity can and will be put on board ship, but enough has been said to show how varied and important are its applications.

The arrangement of supply cables to these consuming devices is a subject which requires some thought, and, in order to be successful and economical in use, the route on which the vessel is to trade must first be considered. Our floating hotel is sometimes in a cold climate, at other times in a hot climate, and frequently it lies in harbour with only a few officers and men in charge.

Under these circumstances supply should always be available when required, yet in such a way that power cannot be wasted by unauthorised or thoughtless persons. For example, a steamer trading between London and Australia would, while in port, require supply available in the daytime for lights in the engine rooms, officers', engineers' and crew's accommodation, and in parts of the ship where there is not sufficient daylight.

In addition, the cranes, winches and other electrically-driven machinery, also the Marconi apparatus, might require a supply. At night it would be necessary to add the cargo lights for illuminating the deck hatches and cargo holds. After leaving London the same lighting would be required in the daytime, with the addition of heaters and cooking apparatus, &c., also the supply and exhaust ventilating fans.

In the evening all lights would be available. At night (say after 11 o'clock) all unnecessary lighting would be cut off, but light and heat would be available in the passenger cabins for use if required. On reaching the Suez Canal the same routine would still be observed, but the supply to heaters would be cut off, and the circulating fans and punkahs added instead, and so on till the end of the voyage.

For the Atlantic trade the arrangement required is not so elaborate, because of the more even temperature during the voyage.

A suitable combination of main circuits for any ship can usually be selected from the following groups. Each group, of course, may be divided into a number of main circuits as found convenient:—

A. *Service Circuit.*—This includes all lights and appliances for the use of officers, crew, stewards and in galleys, pantries and elevators, also for the navigation of the ship. This circuit is usually required day and night.

B. *Evening Circuit.*—This group consists of lights which are only required in the evening, and are not required during the day or night time.

C. *Passenger Circuit.*—This group includes all lights and appliances required by passengers during the evening and night, but not during the daytime.

D. *Heating Circuit.*—Required only in cold climates.

E. *Fan Circuit.*—Required only in hot climates.

F. *Ventilation Circuit.*—Required when passengers and cargo are on board.

G. *Cargo Circuit.*—Required only when loading or discharging cargo.

H. *Machinery Circuit.*—Always required.

Fig. 1 is a diagram of a typical passenger steamer and Fig. 2 that of a trading steamer, showing the arrangement of feeder cables, section boxes, branch feeders and distributing boxes that would be necessary, assuming that these ships were intended for trading in both hot and cold climates.

By arranging the circuits in the manner shown, the electrician or engineer in charge may limit the load on the generating station without inconvenience to passengers or others,

while permitting a free and reasonable use of lights and appliances.

Nature and Voltage of Supply.—On account of the large number of variable-speed motors in use on board ship, and the increased tendency to use them, the best supply for all auxiliary purposes is the continuous-current system. The best voltage to adopt, however, is a question about which there are many opinions. The general practice is to instal at a pressure of 100 volts, while there are quite a number of ships where 65 volts is the rule, and a few at 110 volts. In the British Navy the voltage has recently been increased to 220. The use of metallic filament lamps will tend to keep the voltage low, while the extended use of motors and heaters will make a rise in pressure imperative.

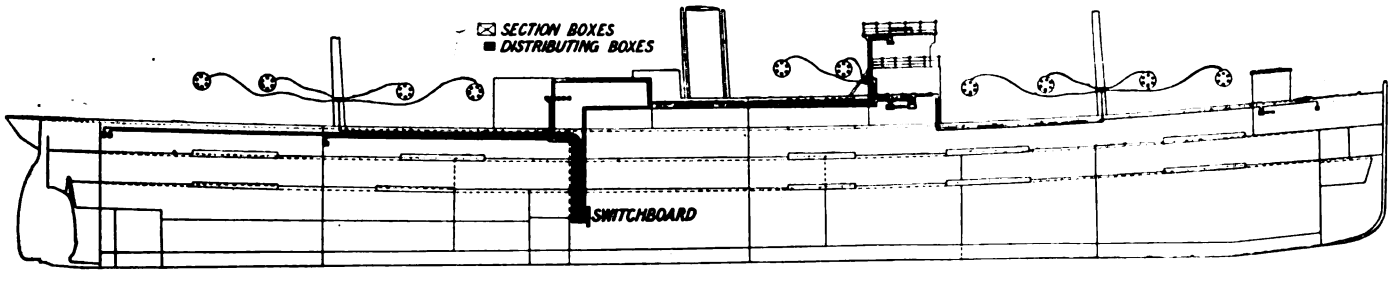

FIG. 2.—PROFILE OF TRADING STEAMER, SHOWING ARRANGEMENT OF FEEDERS, SECTION BOXES, AND DISTRIBUTING BOXES.

To those unacquainted with conditions on board ship it may seem strange that a low voltage like 100 volts is preferred, but a few moments' reflection will show that there is much to be said in its favour, at any rate for lighting and small appliances. Firstly, lamp filaments must be able to withstand vibration. It may be said that there is very little vibration in modern vessels, but in rough weather the stoutest ship afloat will vibrate a great deal when buffeted by heavy seas. Secondly, with increased voltage there is some risk of fire. Imagine a large steamer having five or six decks each crammed with cabins built of wood, and fitted with all manner of combustible furnishings. Think of the miles of wiring that must be installed in these rooms, and of the frequent and hurried alterations that are often made to suit passengers, involving risk of damage to wires. Think of the sea water which at some time or other finds its way, say, to a fitting block through leaky

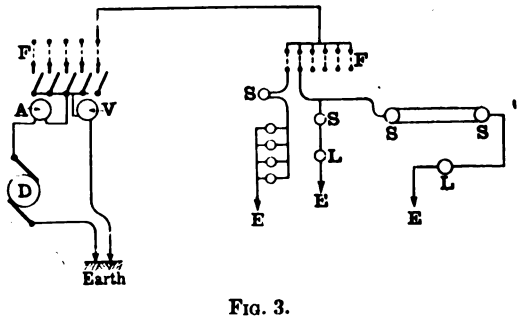

FIG. 3.

D=Dynamo. A=Ammeter, V=Voltmeter. F=Fuse. S=Switch. L=Light. E=Earth.

decks or otherwise; and who shall say that there is not some danger at 220 volts which is entirely absent at 110 volts?

The system which is likely to suit the case of large steamers, at any rate, is the three-wire one, using 220 volts across the outers and distributing on the two-wire system to lights at 110 volts. The middle wire would be earthed through an ammeter, resistance and alarm apparatus at the generator end in the usual way.

Wiring.—At present there are three wiring systems available for use on board ship—viz., the single-wire system, the concentric system and the double-wire system.

Single Wiring.—This system is still a favourite with some shipowners. It is slightly cheaper to instal, but here its advantages end. One insulated conductor only is used, and the return circuit is by the hull or framework of the ship. The arrangement of cables on the insulated pole is similar to that used with a two-wire system, switches being inserted on the live side of the lights (*see* Fig. 3). At each light the return wire is soldered to a brass screw, which is tapped into the nearest beam or plate. Larger cables are soldered into sockets, which in turn are fastened by strong brass bolts to the hull beams. It is essential, of course, in all cases that the contact surfaces be thoroughly cleaned.

The objection to the single-wire system is that, being magnetically unbalanced, it affects the deviation of the compass as the load changes, and renders the compass readings unreliable. In order to reduce this to a minimum, all small conductors within 15 ft. of a compass must be, by Lloyd's rule, arranged on the double-wire plan, and larger conductors must be double wired for a greater distance. Fear of compass troubles, however, makes many shipowners fit double wiring to all lights forward of a line drawn across the ship 30 ft. behind the compass (*see* Fig. 4). This, as a rule, means that the entire forward half of the ship is double wired, leaving only the afterpart to be single wired. The advantage in cost is, therefore, not so great as would at first sight appear, while there remains a grave risk should an earth develop in any wiring near the compass.

Fig. 5 illustrates this point. The section feeder is single until it reaches the point E_2, say 30 ft. aft of the compass, where the return feeder is earthed. Normally there is no unbalanced magnetic field forward of this point, but should an earth occur at E_3, for example, on the telegraph return wire, a portion of the current will return direct through the hull to the dynamo, leaving unbalanced the supply wire to the telegraphs which passes close to the compass. Nor is this all. Should the fault at E_3 be of very low resistance, part of the return current from other lights in the vicinity may find earth at this point also. We will, under these conditions, have unbalanced magnetic fields in, first, the telegraph circuit supply wire; second, the

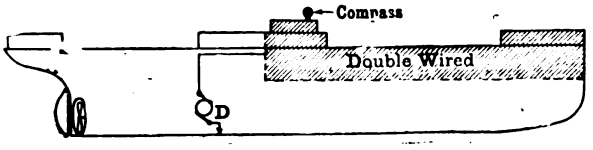

FIG. 4.—SHOWING THE PORTION OF A SINGLE WIRED SHIP WHICH IS USUALLY DOUBLE WIRED.

telegraph circuit return wire (because of the current from other lights finding earth at E_3); and, third, the main feeder (because of the reduced current now finding earth at E_2).

The danger lies in the possibility of the fault occurring at any time without the knowledge of the officer or engineer. The lights burn as usual, no fuse opens circuit to give warning, the switches control the lights as usual; but the compass error comes on in the night time, a time when the utmost accuracy and skill are required in navigating the ship.

It is an advantage to use double-contact lamp-holders throughout a single-wired ship installation. Where single-contact holders only are used, there is danger that a workman may, carelessly or by mistake, connect the live wire to the fitting instead of to the centre contact of the holder, especially

when wiring portable lamps. If, while current is switched on, the fittings be earthed for a moment, the fuse will open circuit on any that have been wrongly connected.

Concentric Wire System.—This system is installed in some vessels, and as a rule the outer conductor is uninsulated. It is obvious that the same objections apply here as in the case of single wiring, but if the outer conductor be even lightly insulated and braided for protection it becomes quite a good and safe method. In most cases it suffers, however, from the use of special joint boxes and connections, which must be soldered and made watertight, and too much depends upon the workman who erects it.

It is not a system which can be readily extended or repaired by engineers or by contractors at a foreign port, and is consequently not favoured by many shipowners.

The Double-wire System is installed in the great majority of ships. By its use the compasses are quite unaffected, and any faults on either pole are readily detected and repaired. Under this title it is proposed to consider the following methods of installing :—

A. Vulcanised rubber insulated wires in wood casing.
B. " " " tubes.
C. " " " lead sheathed.
D. " " " steel sheathed.
E. Twin *versus* single-armoured cables.
F. Special systems.

Before considering methods of installing, a few words in regard to the insulation of the copper conductor may not be unjustifiable. It is the universal practice to insulate small wires with pure rubber and vulcanised rubber compounds; and, perhaps, no better wire is available at present than that insulated to the standard specification of the British cable makers, but there is still room for improvement. Rubber-insulated cable, when exposed to the action of sea air and sea water, deteriorates in time, and it is due to this that special precautions must be taken in installing on board ship.

Paper insulation depends too much on its lead sheathing to be thought of for branch wiring work, but there is great need for an insulating substance which will remain unaltered under the influence of electric strain, sea water, sea air and variations of temperature.

Such substances as bitumen, or enamel combined with a fibrous base, might be expected to give better results.

Wood Casing.—For passenger accommodation, rubber-insulated and braided wire enclosed in wood casing makes a good job, and quite a safe job at low voltages, if the casing be kept dry. It is impossible as a rule to find space for casings having a groove for each wire, as is the custom in work on shore at higher voltages. The practice on board ship is to bunch the positive wires in one or more sets of grooves, and the negative wires in corresponding separate sets, according to the space available. Until the day of more perfect and lasting insulating material appears it would be unsafe to bunch positive and negative wires in one groove, but even the bunching of wires of opposite polarity in separate grooves is an argument in favour of a moderate voltage, say not exceeding 110 volts.

Wood casing should be so arranged that the covers may be readily removed without interfering with constructional or decorative woodwork other than the cover itself. Fig. 6, A, B and C, shows some methods of constructing casings with this end in view.

It is in the saloons and lounges, where special decoration is fitted, that one finds most difficulty in arranging proper grooves for wires. The growing custom among shipbuilders is to employ architects to design the woodwork for these places, and these gentlemen are so accustomed to have gas pipes and electric wires fitted under the floor above that they get quite a shock when they find their cherished design must be modified in some way to accommodate electric wires.

Wires should be placed in wood casing with as much slack as possible. It has been observed by many that, after a year or two in use on board ship, wires not only become brittle, but they appear to contract in length. If a wire be erected with a slight wave in a wood casing it will be found in a year or two after to be straight and in tension (*see* Fig. 7). Wires should be plugged into grooves by wood wedges, as shown in Fig. 8.

Although wood casing makes a good job in cabins, it is not at all suitable for machinery or cargo spaces.

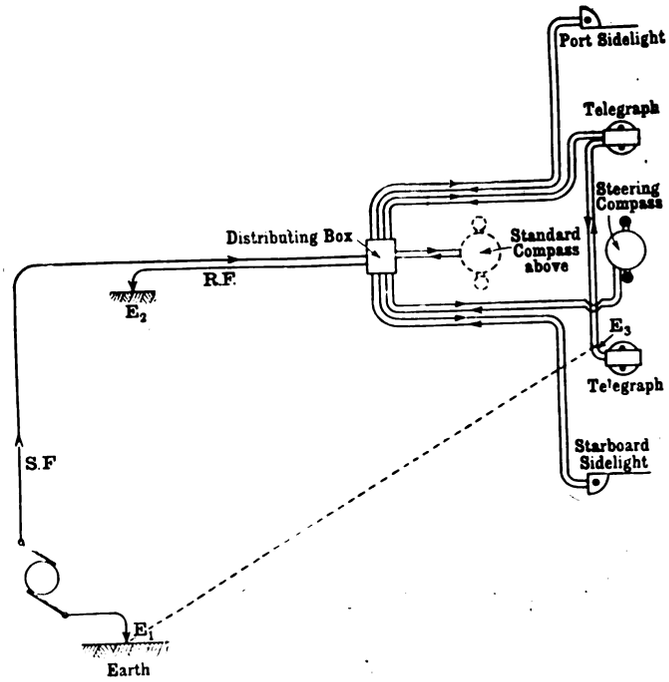

FIG. 5.—SHOWING ARRANGEMENT OF DOUBLE WIRING ON BRIDGE WITH "SHIP" RETURN.
S.F.=Section Feeder. R.F.=Return Feeder.

Tubes.—It might be considered that steel or other metal tubing would form an ideal covering for electric wires on board ship, yet such is not the case, except for vertical runs, where the tubes are open at the bottom. No matter how carefully jointed a system of tubes may be, water will soon collect inside.

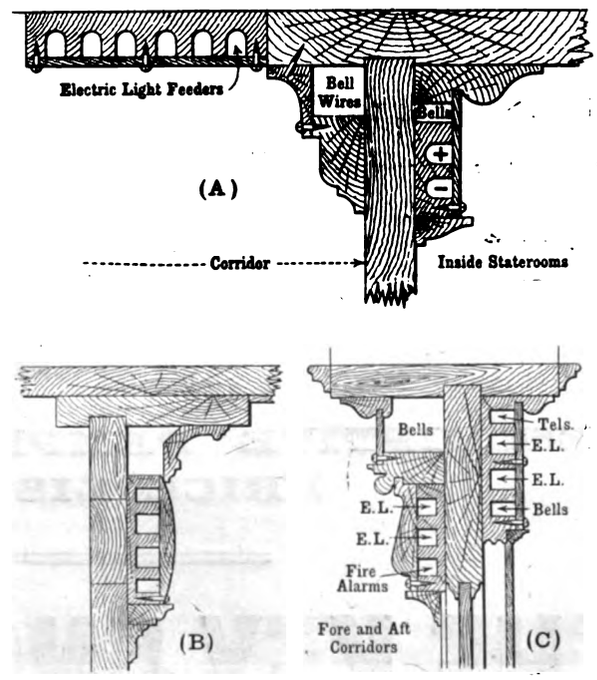

FIG. 6.—CASINGS.

The air is always so moist and temperatures vary so much that there is a continual condensation of moisture inside the tubes, varied by re-evaporation when the tubes become warm. Outlets for condensed water would, in many cases, provide inlets for sea water. Even although outlets be provided at the

lowest points, it does not follow that these points will always be the lowest, for the ship is continually tossing about, and may even have a list to one side during a whole voyage. Tubes, however, are necessary on such exposed vertical runs as on masts, where there is danger of mechanical damage, and also at all points where wires pass from one deck to another.

Tubes with insulating lining have been used in some vessels, but their success has not been great, probably on account of the flimsy nature of the draw-in boxes, and the ease with which water can enter at the inspection covers and joints. Even if a tube system had not the faults described, it is probable that the wires would be damaged in course of erection, for, under the conditions of modern shipbuilding, where hundreds of workmen are employed in a limited space, wires are certain to be trampled and damaged while they are being drawn into the tubes.

Lead Sheathing forms an excellent covering for wires on board ship, but its use is limited to spaces where it is not exposed to mechanical injury. It can be erected very neatly by skilled men, and when painted resembles the beading of a wood moulding. It is usually fastened by brass clips screwed to the wood or iron work of the rooms, and, on account of the plastic nature of the lead covering, these clips must be closely spaced, say 6 in. to 8 in. apart. When two or more wires enter a fitting block they should enter at the same side, and the sheathing be connected together as shown by the bonding saddle at B, Fig. 9.

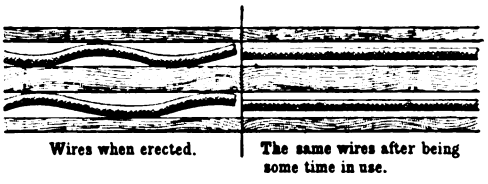

FIG. 7.—ILLUSTRATING CONTRACTION OF WIRES.

So long as lead-sheathed wire is erected on the surface and painted it lasts well, but when enclosed in wood casing, or placed behind wood mouldings, or in any space where fresh air does not freely enter, the lead is sooner or later reduced to a white powder. It is probable that lead acetate and lead carbonate are formed by the reducing action of vapours arising from the wood, particularly in hot climates.

Armoured Wire.—For use in engine rooms, boiler rooms, cargo holds and similar spaces, where wires would be exposed to damage, the best form of protection is a sheathing of galvanised steel wires, with a substantial packing of hemp, treated with waterproof compound, underneath the armour.

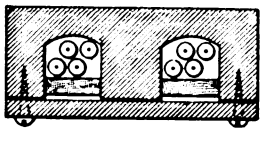

FIG. 8.—METHOD OF FIXING WIRES IN CASING.

It has been observed that when a lead sheathing is also used under the armour, and the cable exposed to sea water, the cables do not last for many years, and that when deterioration once starts the end comes rapidly. The following is a probable explanation of this destruction :—

In order to prevent the steel wire sheathing from cutting into and damaging the lead sheathing, the latter is served with tape or braiding and soaked in compound before the armouring is put on. In course of time this taping becomes saturated with sea water, and virtually becomes the exciting liquid in a voltaic cell, of which the lead sheathing and the zinc galvanising form the couples. A small difference of potential is set up between the lead and zinc, and it only remains for accident or other cause to connect the lead and zinc in order to complete the circuit. The difference of potential, of course, is small, but the area of metal exposed to the action is large, and the destruction correspondingly great.

At first, while the armour is all coated with zinc, the direction of this current is from the zinc through the separator to the lead, and the zinc is consumed, but eventually the zinc coating is removed and the couples become iron and lead. When this occurs the direction of the current is reversed, and the lead becomes the consumed metal, till in a short time the insulation is exposed to the action of the sea water.

It has also to be noted that, as the lead sheathing, separator and armour are all in the leakage path of the cable, the action described may be retarded or augmented by leakage, according to the polarity of the core. Thus, in the case of a +core, the zinc-lead couple would be opposed and the iron-lead couple assisted by the leakage current.

Armoured cables without any lead covering last exceedingly well if special attention be paid to the braiding and waterproof compound provided between the cable and armouring.

Twin Cables.—For the smaller cables and wires such as would be used for sub-mains and distributing feeders, there are some

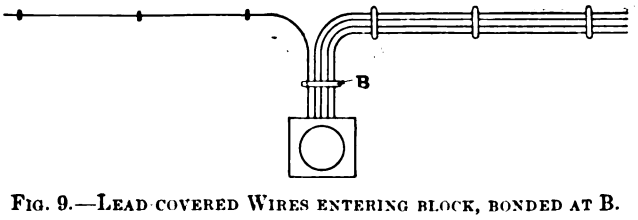

FIG. 9.—LEAD-COVERED WIRES ENTERING BLOCK, BONDED AT B.

advantages in using twin cables. First, a twin cable is larger and stronger than two single cables, and, on account of the extra packing required to make the cable circular, the insulation is better protected. Second, the rules of Lloyd's Register require an armoured cable in cargo spaces to be sheathed with wire of not less than No. 15 S.W.G. The small sizes of single wire are not easily sheathed with wire of this size, the sheathing is not proportional to the conductor and insulation, and an unsatisfactory cable is the result. Twin wires, on the other hand, can be most suitably armoured with the required gauge of wire. Third, a twin cable will stand a severe blow or heavy pressure without showing external signs of damage to the insulation.

The conductors may even fuse together within the sheathing without danger of causing a fire outside. Two cases from actual experience illustrate this point very clearly. A twin cable was carried along an engine-room bulkhead and crossed behind a vertical water pipe, there being about ¼ in. clearance between the pipe and cable. During the trial of the electrical installation a short-circuit developed in this cable and opened the fuse protecting it. An examination of the exterior of the cable revealed nothing, but a loop test quickly located the fault in the vicinity of the pipe referred to. On opening the cable at the fault the insulation was found partly burned away and the conductors fused together. The damage was due to the bulging of the steel bulkhead while the bunker was being filled with coal, and the cable was crushed between the pipe and bulkhead.

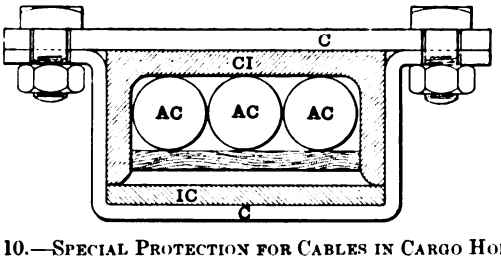

FIG. 10.—SPECIAL PROTECTION FOR CABLES IN CARGO HOLDS.
AC = Armoured Cables. IC = Iron Cover. CI = Channel Iron. C = Clamps (spaced every 3 ft.).

A similar fault, on the other hand, occurred where two separate armoured cables were used. In this case an expansion pipe was bolted hard against two cables while current was passing in the latter. As the bolts were being tightened a partial "short" developed across the two cables, through the

Digitized by Google

armouring, which quickly burned away, and before the circuit could be switched off a hole had been fused in the pipe also. This happened at the time of light load, and the current did not reach 120 amperes, for which the fuse was adjusted.

Fourth, a twin cable is more convenient to work with than two single cables, is more suitable also for fitting into watertight packing glands at fittings, switches or distributing boxes, and its use makes connections at fuse boxes more simple, although this is not an important point.

Special Systems.—"Stannos" wire, invented by Messrs. Handcock and Dykes, has only recently been put on the market, and there has not been time as yet to give it a fair trial for ship work. In the "Stannos" wire the conductor, which is insulated and taped in the usual way, but not braided, is wrapped round twice with a closely compressed sheet of tinned copper, forming a watertight sheathing.

Another wire, known by the name of "Kuhlos," is similar, but only a single layer of brass is used, the two edges of the sheet being folded together to form the joint. This sheathing is not watertight. It seems to the writer that there is in some of these wires an insufficient padding between the insulation and the sheathing. If at least three layers of tape treated with waterproof compound were laid over the rubber the wire would be much more suitable for ship work. Packing between the rubber and sheathing is as important as the insulation itself, not only as protection against blows or similar rough usage, but to protect the rubber at ends, where the sheathing is cut off. If a sheathed wire is to be satisfactory in practice, some safeguard must be used to prevent injury while the sheathing ends are being trimmed, and also to prevent the sharp edge of the sheathing from cutting into the insulation where wires enter junction boxes or fittings in which space is limited.

It is attention to such details as these that makes the difference between a good or bad job where sheathed wire is used.

Another reason why sufficient packing should be inserted is that in small stranded cables, say of 3/20 size, a strand often breaks, and, owing to the twist, and possibly also to the contraction in the length of the conductor previously referred to, the two ends of the broken wire spring out and pierce the insulation. If there is only one layer of tape over the rubber the distance between the sheath and these broken ends is so small that the dielectric soon breaks down. This defect could be remedied by first binding the copper core with a thin layer of strong waterproof tape before putting on the rubber, but probably the best method is to use solid conductors for all single wires smaller than No. 16 S.W.G.

Erection.—No matter how good the cable be, if it is not carefully erected by experienced workmen, it will not last long.

The success of a ship wiring installation depends greatly on a suitable choice of material and carefully considered runs for the wiring. It is not only the quality of material that matters, but the suitability of the material to the position in which it is to be erected, and experience can best enable one to decide this.

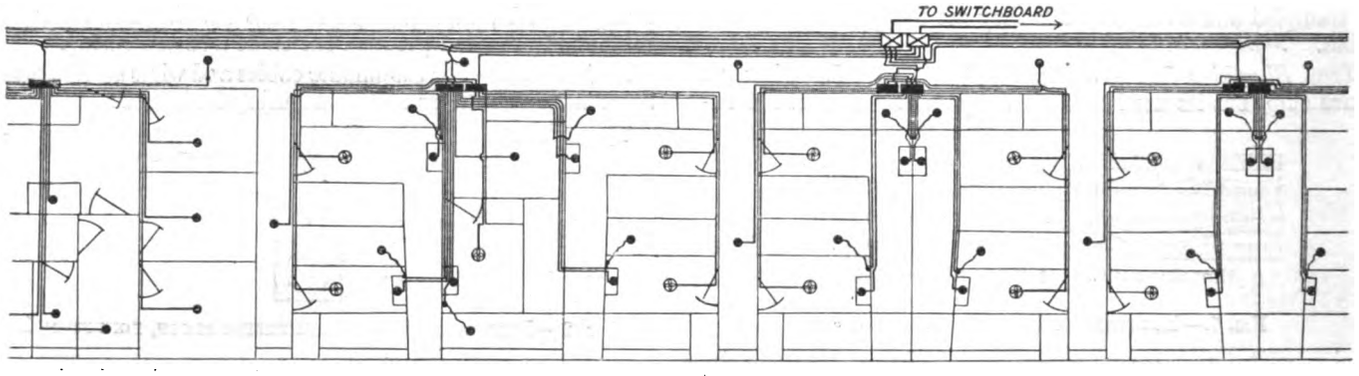

FIG. 11.—DISTRIBUTION WITH FUSE TO EACH LIGHT.

Sharp bends should always be avoided. Holes through beams and plating should be bushed with a material softer than the wire. Where wires pass through a watertight bulkhead, stuffing boxes should be fitted for each wire to prevent the passage of water should one compartment be flooded at any time.

Where wires enter fittings exposed to water, or where moisture may condense and collect, the wires should be led upward into the fitting.

In general it is better to dodge water, to lead it away to another resting place, than to oppose its entrance into fittings, for water has the unhappy knack of finding a way where it is least desired.

Special Protection is sometimes required in cargo holds and spaces where wires would be exposed to excessive damage. Advantage should always be taken of such protection as the beams and girders in the ship afford, but for maximum safety shipowners sometimes prefer to have special protection.

One of the best methods in these circumstances is to fit armoured cables inside strong channel iron bars not less than $\frac{3}{8}$ in. thick having a heavy iron cover, as shown in Fig. 10.

Distribution.—In the majority of ship installations, joints in cables and wires are not now used, and all connections are, as a rule, made on terminals. There are two methods of distribution in general use: first, that in which each light or other apparatus has its own fuse; second, that in which the lights are arranged in groups (usually 3 amperes), each group being pro-

tected by a fuse. In either case it is bad practice to have single fuses scattered throughout the installation, and all fuses should be arranged in proper distributing boxes. In the first system—viz., that of having a fuse for each light—it seems to the writer

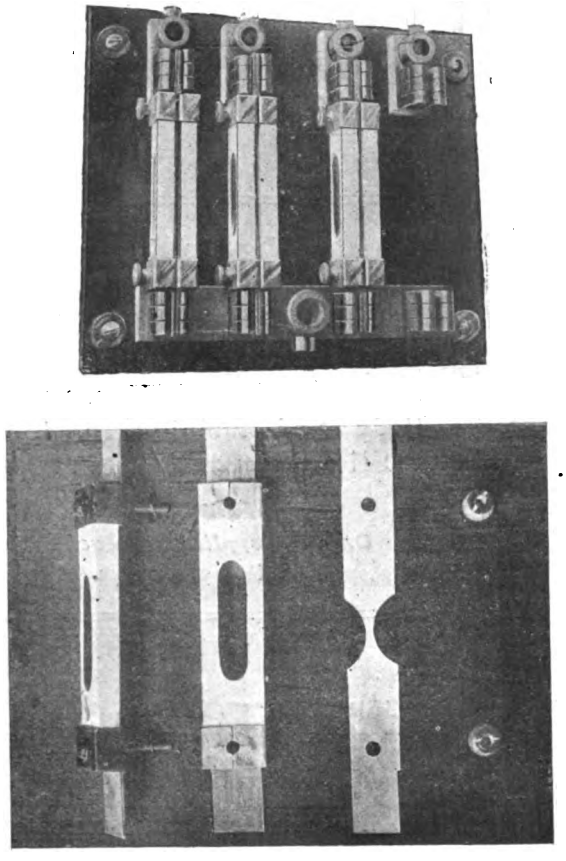

FIG. 13.—"MAURETANIA" FUSEBOARD SHOWING FUSE HOLDER SEPARATELY.

that sub-division is carried to quite an unnecessary extent. The object, of course, is to prevent inconvenience to passengers in any other room but the one in which a fault may be, but faults do not occur so frequently, and are generally of a trivial nature. The objection to this plan is that it requires so many

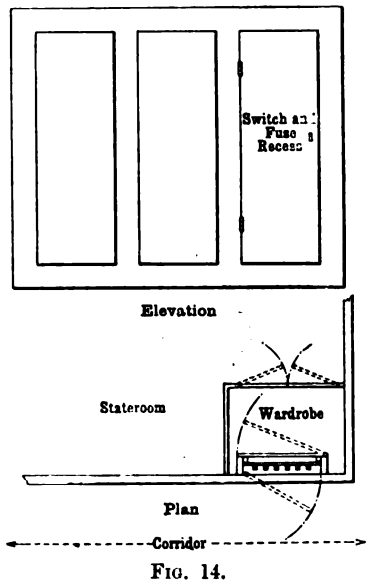

FIG. 14.

small distributing boxes that they give the passages an unsightly appearance.

In the second system the wires are either looped at lights and switches, or extension boxes are fitted for each group. Figs. 11 and 12 illustrate both methods. In either case the sub-mains are carried to section fuse boxes, and main feeders carried from the latter to the switchboard, a fuse being always introduced where the conductor is reduced in size.

Fuse-holders should be of the removable type. They should be so arranged that the contact nuts cannot slacken back by vibration, nor the fuse-holder fall out of the clips, and they should not project much in front of the base of fuseboard. A fuse-holder which fulfils these requirements, known as the "Mauretania," is shown in Fig. 13. It consists of two strips of fireproof insulating material (not porcelain) fitted with sheet copper end pieces and clamping bolts, as shown. The fuse (a strip of zinc or zinc-tin alloy) is clamped between the two halves thus formed, and, owing to the notch on the clamping nut

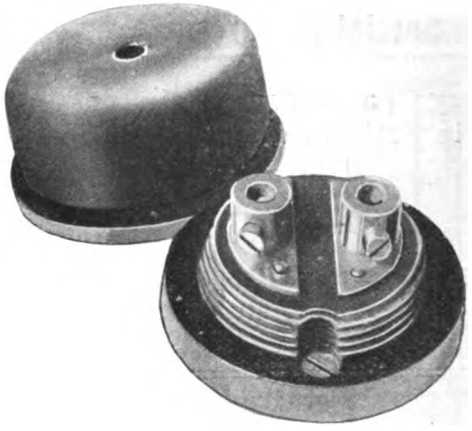

FIG. 15.—ORIGINAL EXTENSION BOX.

which engages at each half turn with the raised line on the sheet copper, the nut cannot turn back except by force. In addition to this, the fuse is also held in contact by the clips into which the holder is inserted. The fuse cannot fall out of the clips, and does not project in front of the terminal clips, which in the 50-ampere size is about 1in. from the base.

It is desirable, wherever possible, to fit fuse boards into recessed spaces, forming the panel in the framework into a door for access to the fuses, and also to have a door behind for access to the wiring, as illustrated in Fig. 14. Suitable places for these recessed fuse spaces are found at wardrobes, linen lockers and pantries.

Extension Boxes were first introduced by Messrs. W. C. Martin & Co., and Fig. 15 shows the original pattern, which is now extensively used. The supply wires and branch wires to lights and switches are connected together by the stout pinching screws shown, in the same manner as connections on ceiling roses. A later pattern, shown in Fig. 16, has many advantages, especially when it is probable that portable lights, fans

FIG. 16.—"TRITON" EXTENSION BOX.

or curling-tong heaters may be added after the installation is completed. Fig. 17 is a diagram of connections, showing some of the most useful applications of this extension box. There are four terminal blocks, two of which are fitted to receive the pins of a two-pin plug, in addition to the ample terminal sockets

for connecting the permanent wiring. For exposed work extensions are fixed inside watertight metal boxes fitted with watertight glands suitable to the kind of wire employed.

As this article does not deal with "illumination and fittings," it is now proposed to describe shortly some of the other apparatus installed on board ship, especially with reference to the necessary wiring.

It is commonly supposed, for example, that electric bell wire need only be insulated with cotton and paraffin wax, but wire of this description would not last for six months on a ship without breaking down. For any purpose on board vessels, whether for bells, telephones, fire alarms or special apparatus

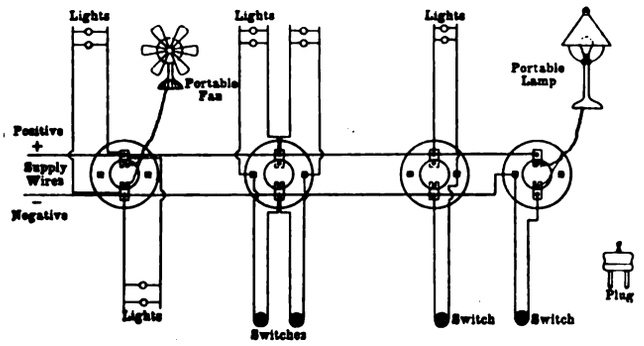

FIG. 17.—DIAGRAM OF CONNECTIONS FOR "TRITON" EXTENSION BOX.

with battery supply, the insulation cannot be too good, and should be similar to that used for electric lighting. Bell and telephone circuits especially are subjected to fairly high inductive potentials; indeed, under conditions which frequently occur on ships, a sharp shock may be obtained from a metal bell push if the metal plate be in circuit.

In long runs of wiring for bells, telephones, clocks, alarms, &c., it is convenient when wiring, and useful afterwards, to have junction boxes inserted at suitable intervals for testing purposes.

Electric Bells.—In a passenger ship of moderate size the bell indicators are generally fitted near the pantries, and the arrangement of wiring necessary is of the usual simple kind; but in larger vessels the bedroom stewards are not required at the pantry, and are stationed near the rooms they have to attend. In this case it is necessary to have local indicators, and also a master indicator at the pantry, for use at night or when the local steward is off duty. A change-over switch is fitted at each local indicator, arranged to cut out the local bell, but not the indicator movement, and to put the master indicator and bell in circuit. In this case one drop is provided on the master indicator for each local indicator.

It is alleged that with this system passengers may not get prompt attention from local stewards, and to meet this objection a very ingenious indicator movement was introduced some time ago. The passenger is informed, by notice or otherwise, that one press of the push calls the local steward, but if the push be pressed a second time the steward at the master indicator gets notice of the inattention.

This is effected by the movement in the local indicator, which at the first call is arrested by a small catch and prevented from dropping the full distance. At the second call the catch is released, and the shutter drops the full distance, closing the master indicator circuit at the same time.

This would be an ideal arrangement, but, unfortunately, passengers, especially when impatient, are in the habit of giving a number of short pushes, and the stewards would really be hindered in the performance of their duties.

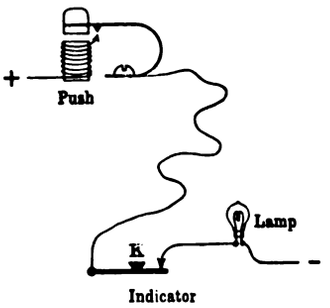

FIG 18.

Bells should not be fitted in indicator cases, but should be placed in positions where the rattle of the hammer will not annoy passengers. In order to avoid this nuisance, luminous indicators are sometimes used. In one system a small electromagnet is fitted in the base of each push, and is in series with the push contacts and a small lamp and closed key at the indicator (*see* Fig. 18).

When the push is pressed the magnet holds the push in contact so long as the circuit remains completed, but on noting the call the steward presses the key K and opens the circuit. The magnet cannot now hold the push in contact, and the press button springs back with a click, which announces to the passenger that his call is having attention.

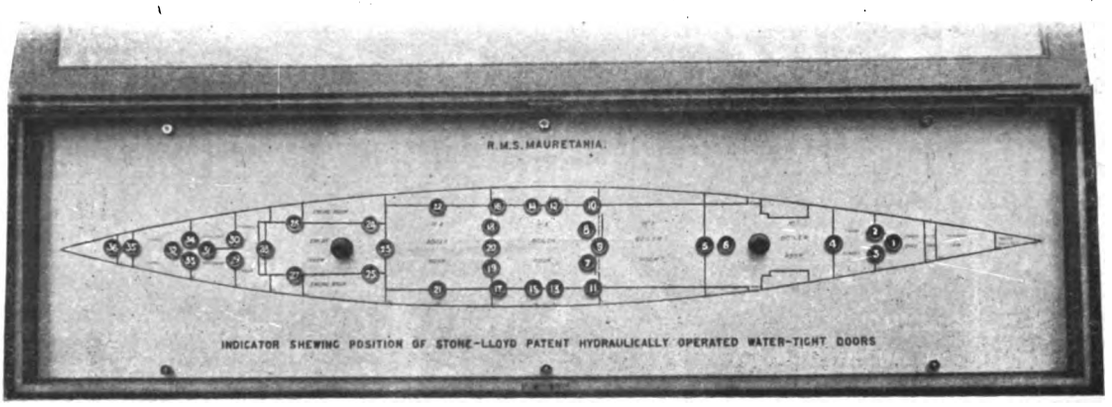

FIG. 19.—INDICATOR SHOWING POSITION OF WATER-TIGHT DOORS.

Another system is that in which the interior of the indicator is illuminated, but the light is blocked by indicator discs. When a push is pressed the corresponding shutter falls and allows the light to illuminate the number exposed. The shutters are replaced by rods in the usual way.

It frequently happens that a number of cabins are arranged so as to be available for either first or second-class passengers. It is then necessary to fit a two-way switch for each room, in a place near the room, but only under the control of the steward. The bell push in the cabin is connected to the central terminal of the two-way switch, while from each of the other switch

Digitized by Google

terminals a wire is carried to the first-class and second-class indicators respectively.

Watertight Door Indicators are frequently fitted in passenger steamers. The indicator screen forms a plan of the ship, with a small electric lamp fitted to indicate the position of each watertight door (*see* Fig. 19). At each door a special push is fitted, which completes the indicator lamp circuit when the door is closed.

Should the officer on duty wish to know if the doors are open or closed, he closes the main switch at the indicator, and immediately the closed doors are indicated by a light in the screen. These indicators ought also to have a test key for each lamp in order to prove whether a door is really open or the lamp filament faulty.

Watertight doors are often operated by hydraulic power, and all the doors in the ship may be opened or closed simultaneously by means of a single two-way valve under the control of the officer, while at the same time each door may be operated locally independently of the master control.

There is scope here for electrical apparatus to perform the same duty, for, considering the cost of installing a special hydraulic pump, with high-pressure water pipes and special fittings, it surely is possible to make use of the electric supply, which is always available, for this purpose at less cost than the hydraulic system.

Conclusion.—There are many other special purposes for which electricity is used on ships, but space does not permit of further reference, and, while much has already been accomplished, there remains a wide field for further thought and activity.

Marine Cables on Ship Board

While the success of a marine electrical installation depends largely on the reliability and efficiency of the generating plant, even more is the system dependent on the feeders and distributing cables. The generating plant is subject to constant supervision, but the distribution system cannot be kept under the eye of the staff and must therefore be capable of carrying its load and maintaining its insulation at all times. In the present issue special attention is directed in one of the contributed articles to ships' wiring and the methods usually adopted in the distribution of electrical energy about a vessel. From this it will be gathered that cables and wires are now run to the most distant parts of a ship, where they are subject to the attacks of moisture, sea water and various other influences.

In a modern liner the capacity of the generating plant and the load on the distributing system will exceed those usually met with in a good-sized town. There is, however, this difference. In a land installation the distributing network is under the constant supervision of the mains staff. On board ship the same amount of attention is not paid to the cables after they are once installed, the quality of the conductor and its insulation being relied upon to maintain absolute continuity in the supply.

On the ss. "Mauretania" over 200 miles of wires and cables are installed. These consist of cables of many sizes and types and they supply energy for all the many purposes to which electricity is put on shipboard. There are the large main cables, feeder cables, power mains, telephone cables, switchboard cables, bell wires, lighting wires, flexible leads, &c. They are all insulated with best quality vulcanised indiarubber and are protected in various ways. The main feeders are braided with two coats of asbestos yarn impregnated with

FIG. 1.

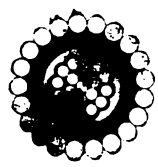

FIG. 2.

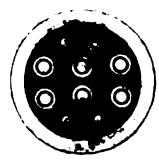

FIG. 3.

special fire-proof compound, and other cables have an armouring of lead or galvanised steel wire, or both. Messrs. W. T. Henley's Telegraph Works Co. supplied the cables for the "Mauretania" and "Lusitania," and we produce some sectional illustrations of a few of those in use on these splendid ships.

Fig. 1 shows a 19/17 tinned copper conductor insulated with pure and vulcanised indiarubber (two coats), waterproof taped and sheathed with a solid drawn lead tube. This is afterwards served with jute and subsequently wire armoured. This cable is installed on the "Mauretania." Fig. 2 is a 19/16 tinned copper conductor pure and V.I.R. insulated (two coats) waterproof taped, braided with jute and wire armoured. Fig. 4 illustrates a 1·5 sq. in. cable, 127/112 tinned copper, pure and V.I.R. insulated. These two were also installed on board the "Mauretania." This cable is finished off with waterproof tape, braided overall with two coats of asbestos and finally treated with Henley's fire-resisting compound, and generally constructed in order to withstand the great heat of the engine room.

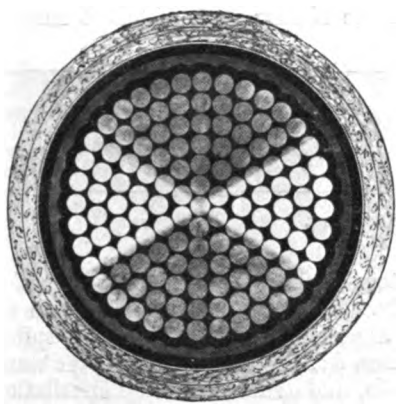

FIG. 4.

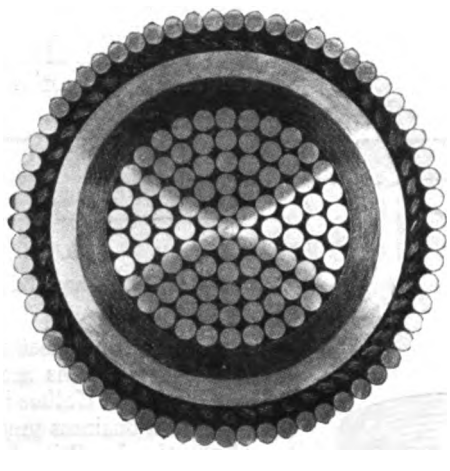

FIG. 5.

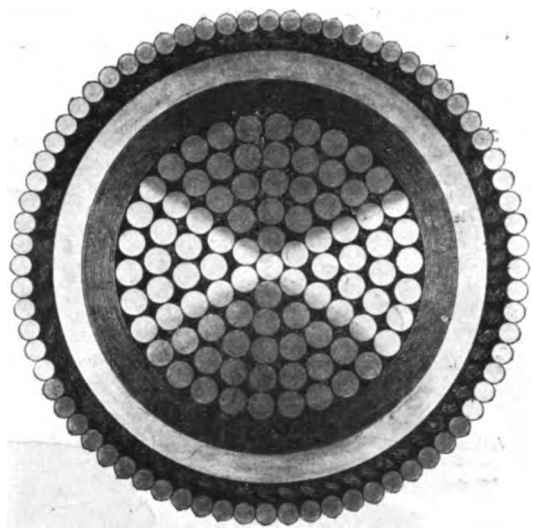

FIG. 6.

Modern battleships perform many operations by electric power which a few years ago were entrusted to steam, while at the same time a large number of mechanical devices are electrically driven which were never previously driven by any other agent. We illustrate samples of Henley's cables now

Digitized by Google

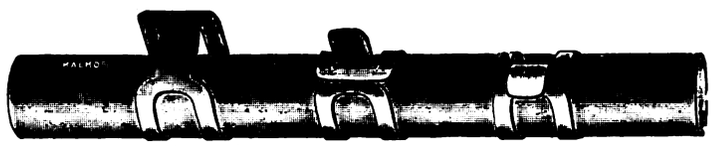
being fitted in H.M.S. "Bristol," being built by Messrs. John Brown & Co., at Clydebank, and H.M.S. "Falmouth," being built by Messrs. William Beardmore & Co., at Dalmuir. These cables have also been supplied by Messrs. W. T. Henley's Telegraph Works Co. (Ltd.), who have supplied cables for many battleships, cruisers, &c., practically ever since electric cables were first used.

We illustrate in Fig. 3 a 10-core V.I.R. cable (16s tinned copper conductors) which is laid up with wormings and sheathed with a solid-drawn lead tube. This has been installed on H.M.S. "Bristol." In the same vessel a 1 sq. in. ring main, similar to that shown in Fig. 5 has been installed, this being paper insulated, lead covered, and afterwards jute served and wire armoured. On board H.M.S. "Falmouth" a 1·5 sq. in. conductor, also paper insulated and lead covered, protected with jute and wire armouring has been installed and is shown in Fig. 6.

These are typical of the heavy character of the cables now installed on board ship, and they serve to indicate the high standard of Henley's cables for this class of work.

Tinned Tube Wiring for Ships

The Kalkos system of wiring, with tinned brass tubes for the reception of the insulated conductors was introduced some three years ago, and many important installations have been



KALKOS TUBE SHOWING BUCKLE FIXING CLIPS.

carried out. In all steel conduit work the problem of condensation is a troublesome one to solve, the trouble being accentuated particularly in ship installations on account of the wide differences of temperature which a vessel experiences in travelling to different quarters of the globe. It is these temperature changes, many of which occur rapidly, that produce condensation in steel conduit, but which, the makers of Kalkos claim, have no effect upon their system of tinned brass tubes. In order to engender confidence in the system, the Sun Electrical Co., who are the pioneers and present suppliers of Kalkos, are prepared to renew any length of C.M.A. cable which fails, on account of condensation, within three years of its being drawn into Kalkos tubing. Quite naturally the guarantee is conditional upon the work of installation being in accordance with the company's standard specification. It may be noted here that the Kalkos conduit system complies with the L.C.C. regulations, and is passed by that body for installation on licensed premises.

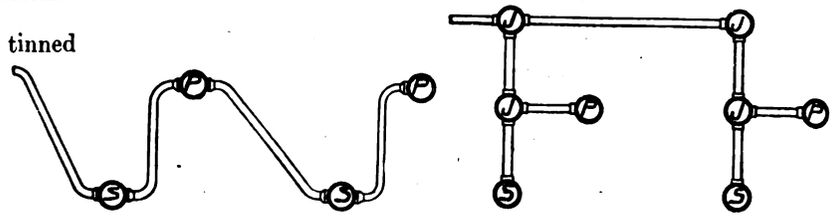


DIAGRAM SHOWING DIFFERENCE IN LAYING OF KALKOS (ON LEFT) AND STEEL CONDUIT.
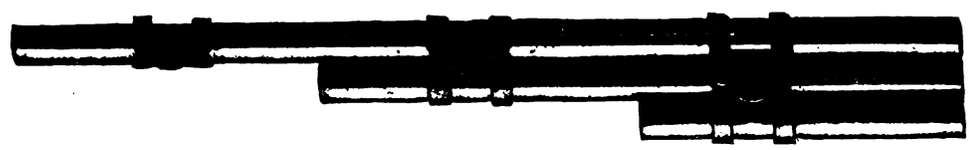
S=Switch P=Light. J=Junction Box.

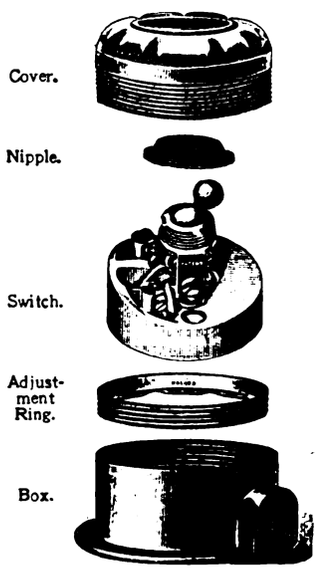
In the Kalkos wiring system, tinned brass tubes are first installed, and the insulated wires are subsequently drawn into them. A complete scheme of boxes and accessories has been provided in connection with the system, and the accompanying illustrations depict the patterns commonly employed. A standard pattern of box has been devised, and with this a variety of fitments with switch, wall socket, pendant and bracket outlets can be effected. The boxes are on this account interchangeable throughout. An important feature of these Kalkos boxes is the amount of flexibility in the matter of entry and exit which they afford. Wires may be brought in at the bottom and out at any point of the side.

ONE, TWO, OR THREE-WAY OUTLETS FROM KALKOS POXES FOR STANNOS WIRES.

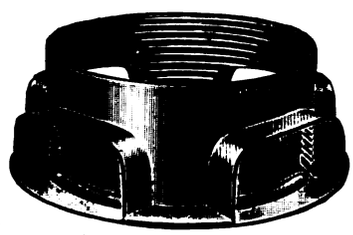
In the space of the present article it is not possible to detail the many accessories of the Kalkos system, but it may be remarked that a most extensive range is presented for selection. All of these items are based on practical experience in the installation of Kalkos in many large public buildings, hospitals trade and business premises, &c. The system bears the stamp of practice in all its details, and as far as marine installations are concerned a number of vessels of the private yacht pattern have been carried out.



STANNOS WIRES AND BUCKLE CLIPS.



TYPICAL KALKOS BOX, AS USED WITH SWITCHES, CEILING ROSES, WALL SOCKETS, &c.



KALKOS FOUR-WAY BOX.

The brass tubing employed in Kalkos wiring is heavily tinned inside and out, and all accessories, such as boxes, &c., directly connected to the tubing are treated in a similar manner. The system is accordingly particularly suitable for marine work in that the tinning effectually protects the brass from the action of the sea air, salt spray, &c. The whole of the work of connecting up the tubing and boxes is done by sweating, consequently, a watertight joint is made at all coupling points. The tubing becomes, by this process of soldering, both electrically and mechanically continuous.

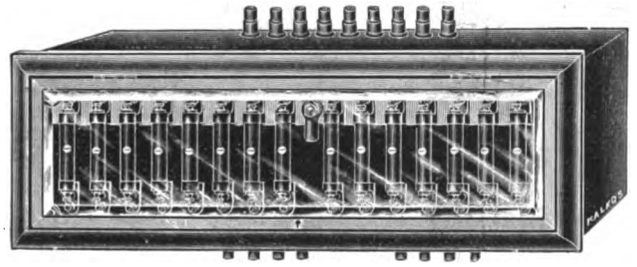
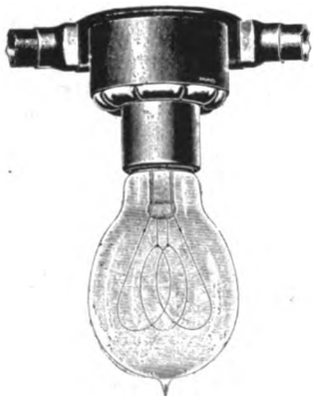
The makers of Kalkos claim that the system is ideal for ship-work, on account of the continuity of the tubing, and the facilities thus afforded for the use of the tube as the return conductor for concentric system. Kalkos can be satisfactorily employed for the main and branch runs about the ship, and with equal facility on the surface or behind panelling. It is exceptionally neat as a surface system. In connection with the Kalkos system Stannos wires are employed to a large extent, the two together forming what is known as the O.S. wiring system. For the interconnection of these two systems special outlets at boxes and other accessories are available, and these maintain the electrical and mechanical continuity of the outer conductor in a simple yet effective



KALKOS DISTRIBUTION BOX FOR CONCENTRIC WIRING, USING TUBE AS RETURN.

manner. It is difficult to conceive of any more flexible, and we might even say any more ideal, system than that in which Kalkos and Stannos are combined in the way above suggested. It is thus claimed that Kalkos tubing overcomes the difficulties of condensation in the feeder and distributor runs about the vessel, and Stannos affords a handy yet neat method of reaching switch and light outlets, and more particularly in surface work.

We may mention that Stannos wires are made by Messrs. Siemens Brothers & Co., and are manufactured with a 10 mil tinned copper taping. These wires, in combination with Kalkos boxes, as noted above, make a very satisfactory and watertight job; and as the sheathing can be employed as the earthed return, an efficient concentric



KALKOS WATERTIGHT LAMP-HOLDER.

ORDINARY WATERTIGHT FITTING WITH ADAPTOR USED ON KALKOS.

system is afforded; the sheathing being also tapped on to the hull at various points. Until recently Stannos wires were only made in sizes up to 7/20, but 7/18 and 7/16 Stannos wires have now been placed on the market. As the voltage adopted for electric lighting on vessels is usually low, the currents flowing are larger than in installations on land, so that the larger sizes of wires mentioned above should prove useful.

Although Stannos wires have only been on the market for little more than a year they are now well known to all electrical engineers, but as marine engineers are usually not so conversant with electrical progress, it may be as well to give the following brief explanation of this system of wiring.

Stannos wires are made by encasing ordinary rubber-covered conductors in tinned copper. A sheet of this latter is wrapped twice round the cable, the second lapping being thoroughly soldered to the first. It will be seen, therefore, that the cable is absolutely impervious to moisture; other features of the system being its great flexibility and the ease with which it can be installed. The metal sheathing can readily be removed, and special continuity fixtures are provided for rendering the outer casing continuous where ceiling roses, switches or other fittings are installed.

As to the labour cost of the Kalkos system, it is claimed by the makers from their extensive experience, that this item is very low because of the ease with which jointing and bending of the tubes can be effected. Again, in drawing in, it is not necessary to make provision for special draw-in boxes, and further the wires can be pulled round four to six bends, owing to the smooth interior surface of the tubes. The work of sweating up the tubes to the boxes at different points of an installation can be easily and quickly carried out, and is, we understand, completed more readily than screwing.

Kalkos wiring makes complete provision for the use of every pattern of switch and pendant accessory, and any desired form of fitting, ornamental or otherwise. In the matter of watertight fittings the Kalkos system provides an outlet for a light in which the lamp holder does not require to be enclosed in a special fitting. The adjoining illustration explains the details of this fitting. The lamp holder is enclosed by a coned socket, and a rubber ring is then slipped over the lamp holder cap. By the provision of a shade ring on the holder ordinary glass shades can be used. On the other hand the more usual bell glass can be fitted to the same pattern of Kalkos outlet box, with no other alteration than the screwing in of a suitable adaptor. Bulkhead fittings can be adapted to Kalkos in a somewhat similar manner.

Ship Wiring with Key Spring Conduit.

The marine electrical contractor is faced with practically the same problems in the selection of a suitable method of wiring as his land confrere, while he has a greater number of special conditions to meet. Finality has by no means been reached in ship-wiring systems, and it will be of interest to describe the features of the latest comer in the field. This is known as Key Spring Conduit, a name which aptly conveys the idea of the principle adopted; the conduit employed is divided into two parts, (1) troughing, and (2) cover, and the latter is so shaped that it can be sprung over the former. Key Spring Conduit may be briefly described as a steel casing and cover system which dispenses with the drawing in of insulated conductors. The work of erection is similar to that of wood casing, that is, the protecting conduit is first fixed in position, the wires are laid in place and the cover is put on; there is, however, a marked saving in time in favour of Key Spring Conduit. The actual cutting, bonding (and bending where required), fixing, wiring and springing on of the cover are speedily performed and with a degree of permanence in the completed work which wood casing never could and never will possess. At the same time it is important to note that with Key Spring Conduit the wires can be examined at anytime even while current is passing.

To the marine electrical contractor a conduit system which removes the risks of abrasion of the insulated conductors and which appears to strike at the root of a trouble that often occurs with steel conduit work—viz., condensation followed by rusting of the interior surface of the conduit—should strongly appeal. Key spring conduit is not a sealed system, the construction, in fact, provides for free ventilation and consequent evaporation of any moisture that may find its way into the conduit. It is claimed that this feature tends to prevent accumulation of moisture just as a house with open windows keeps much dryer than a closed-up house. At the same time, the overlap of the conduit cover and fittings effectually prevents direct access of water.

Digitized by Google

A further great advantage is secured by the fact that the above construction permits of the interior surface of the conduit being more thoroughly coated with enamel than is possible with any closed conduit, thereby effectually preventing the formation of rust. Key Spring Conduit and its accessories

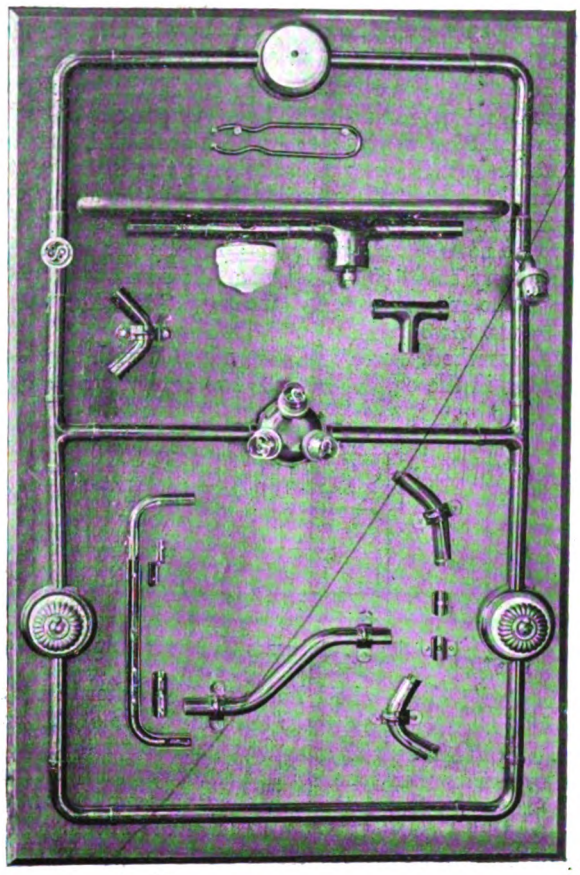


FIG. 1.—SHOWBOARD OF KEY SPRING CONDUIT, DEPICTING PRINCIPAL PARTS.

are only just being placed on the market by the Key Engineering Co. Consequently, no opportunity has been given to marine electrical contractors to test its merits. They will, however, gather from the following description that many advantages are offered by Key Spring Conduit and that it will be worth a trial on a practical scale.

The elements of Key Spring Conduit are neatly displayed on the showboard illustrated in Fig. 1. The conduit is comprised of a semicircular troughing and a semicircular cover which springs over it. Than these two items nothing could be more simple. The general scheme of the system is completed by fixing saddles, tees, elbows, bonds, and bracket and pendant fittings; the special tools required are a hand punch and a hand riveter. The accompanying illustrations (Figs. 2 to 5) depict the more important of these in greater detail than they appear on the showboard.

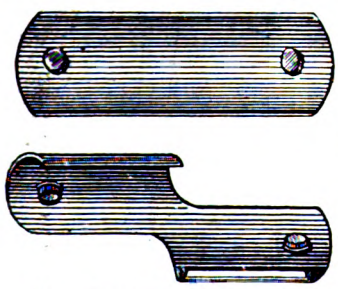

FIG. 2.—BONDING PIECES.

The troughing can be fixed either directly to the wall or ship's side by countersunk screws passing through the bottom of the troughing, or it may be secured to a saddle by a semi-circular clip about 1 in. wide, which passes over both troughing and cover. Where the saddles are used the conduit is held slightly away from the fixing surface so that moisture can run down between the two.

With all conduit systems the question of efficient bonding is recognised to be of the utmost importance. The system adopted for bonding Key Spring Conduits appears to be a particularly efficient one. The lengths of conduit are electrically and mechanically connected by a small steel bond (Fig. 2) and the joints between this and the troughing are made by riveting. Each bond has at each end two copper rivets, and these pass through holes punched in the ends of the troughing. For the punching of these holes and the clinching of the rivets special tools are provided (Figs. 3 and 4). The tools are light to handle and can be used with the conduit in any position. The bond is permanent and of negligible resistance. The cover is easily lifted off by a forked tool which engages with the undersides so that depression of the handle levers the cover away from the troughing.

The Key Spring fittings are all designed to spring on to the troughing. After wiring up the lampholders and bracket, ceiling fitting or three-light cluster, it is only necessary, in order to fix the particular outlet firmly in place, to press the fitting over the troughing and cover. No screws, wood blocks, unions, adaptors or reducing nipples, are facts which cannot fail to impress the contractor.

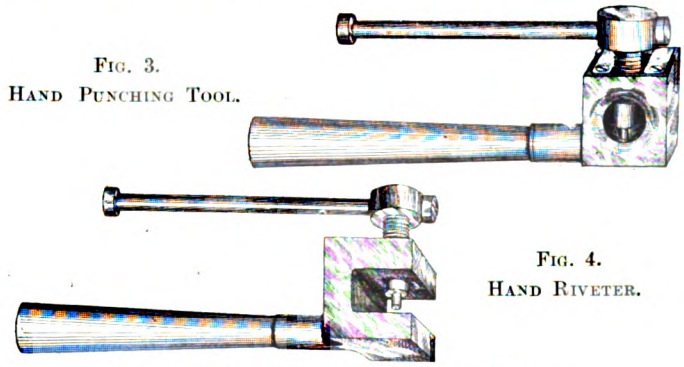

FIG. 3.
HAND PUNCHING TOOL.

FIG. 4.
HAND RIVETER.

KEY SPRING TOOLS FOR BONDING CONDUIT.

The illustration given of the three-light cluster (Fig. 5) shows that this is made up of two parts, one screwed directly to the spring clip for attachment to the troughing and the other, carrying the three holders, held in position by three turned-down lugs, which grip the flanged edge of the fitting. A slot in this flange admits of the passage of one of the lugs, so that a quarter-turn only is required to secure the lower half of the fitting in place. Bracket outlets are, of course, in one piece only, and sprung directly on to the troughing. The actual wiring of fittings can be done on the bench, and their position can be altered as required.

Any number of wires up to the limits of the troughing can be enclosed by the conduit. When laying in, as distinguished from drawing in, the wires, the work is facilitated by the use of small clips, which prevent the conductors from falling out of the troughing prior to the springing on of the cover. The latter

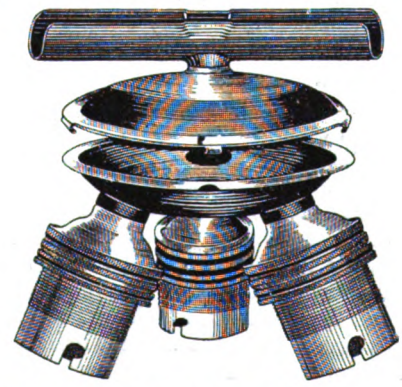

FIG. 5.—THREE-LIGHT FITTING FOR KEY SPRING CONDUIT.

operation is performed when the last of the wires is laid in the troughing.

In conclusion, it may be remarked that the system appears to meet many of the principal objections to ordinary conduit wiring, and it will be interesting to follow its future development. The Key Engineering Co. have prepared a quantity of useful data on the subject of the conduit, and they will furnish any information required.

Electric Steering Gear.

BY A. P. CHALKLEY, B.Sc.

Summary.—A number of systems of electrical steering are described, and in particular those of the Union Electricitäts Gesellschaft; Pfatischer; Siemens Brothers; Clarke, Chapman & Co.; and Brown Brothers (the Brown-Haigh system).

Though in other matters concerning the use of electricity at sea it cannot be denied that England is well to the fore, very little has been heard regarding the adoption of steering gear operated wholly or partially by electric power, though in several other countries considerable progress has been made in the matter, and electric steering gears are doing successful work on many important ships. Before it was proposed to operate actually the rudder by means of electric motors the question of controlling the usual steam steering engine by electricity instead of by hand, or hydraulic power, was very carefully investigated by many engineers, and several methods are now in use for this purpose. The navigating house of a ship is usually well forward, and the steering engine is naturally placed as far aft as is conveniently possible and almost always very low in the boat. The distance between the steering wheel and the engine is therefore considerable, necessitating either an auxiliary steam engine near, or in, the wheel house for operating the engine slide valve by rods and links, or else hydraulic power for the same purpose—both systems being to some extent uneconomical and cumbersome. The former is particularly inconvenient owing to the great length of steam piping required and the friction of the mechanism, while the latter is not entirely safe and is usually duplicated.

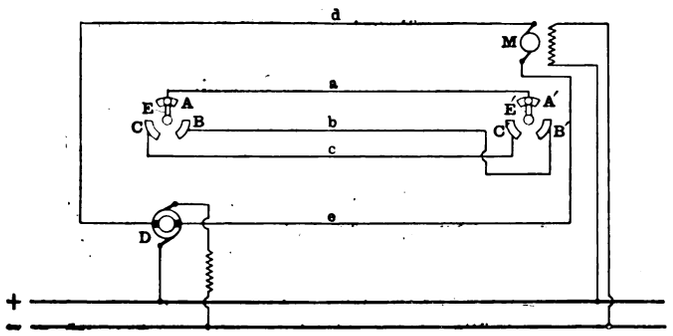

FIG. 1.—ARRANGEMENT OF ELECTRICAL CONTROL OF STEAM STEERING ENGINE.

In all stearing gear the two absolute essentials are entire reliability of the apparatus and synchronous motion of the steering wheel and the rudder; that is to say, any movement of the wheel must cause an exactly corresponding and immediate motion of the rudder. A properly designed electrical system can accomplish this with great satisfaction, but there are one or two points in connection with it which must be borne in mind, and this applies not only to any electrical arrangement for controlling a steam steering engine, but more particularly to motor-driven steering gear, as described later. One of the earliest methods for electrical regulation of steam steering engines was that employed on the Russian cruiser "Bogatyr," nearly 10 years ago, and this is shown in Fig. 1. By means of spur gearing, the steering wheel operates a circular commutator switch D, which cuts off the current from the main ship's circuit when the wheel is in its normal position, a slight movement in either direction causing current to flow through a controlling circular switch with three contacts, A, B, C, mounted on the same casing and also operated through gearing at the same time. This switch is connected by wires to a similar switch with an equal number of stops, A′, B′, C,′ which is operated through gearing by the electric motor M; this works the slide valve of the steering engine, the motor being separately excited from the ship's main circuit. On turning the steering wheel and moving the contact arm E on to the stop B, current flows along the wire *d* through the motor armature, which thus begins to rotate, causing the contact arm E′ to move in the direction of the arrow, and when contact is made with the stop B′, the wire *b* short circuits the armature, which then ceases to rotate. Similarly, if the contact arm E be moved on to the stop C, current flows in the opposite direction through the motor armature, due to the commutator switch being reversed, and the motor continues to run until the arm E′ makes contact with the stop C′. The arrangement has operated very satisfactorily and the chief point to be noted in the design is to make the resistances of the wires very small compared with the armature resistance, otherwise the motor will continue to rotate when short-circuited by the wires *b* or *c*.

Another method, which has been adopted with considerable success, lies in the employment of two similar motors, one of

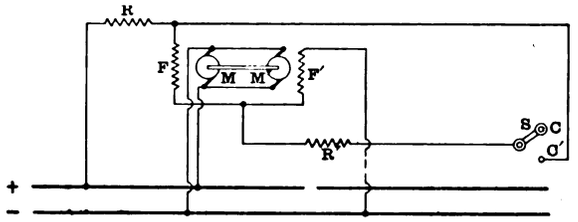

FIG. 2.—U.E.G. ELECTRIC STEERING GEAR.

which is placed in the wheel house and the other in the steering engine room and this works the slide valve of the steering engine. The terminals of the motors are coupled together so that they must run in synchronism, and to ensure further that this shall be so, each armature shaft has three slip-rings mounted on it, which are electrically connected to the windings in order to provide a three-phase current, the two sets of slip-rings being joined by wires. As the slip-rings are connected at similar points, if one motor is slightly out of synchronism with the other, current flows between the armatures, one of which accelerates until synchronism is reached again. Each motor is separately excited from the ship's circuit and the speed and direction of rotation are controlled by a rheostat operated through the steering wheel. In another similar system the motor working the steering engine slide valve, is controlled by a switch operated through an auxiliary synchronous

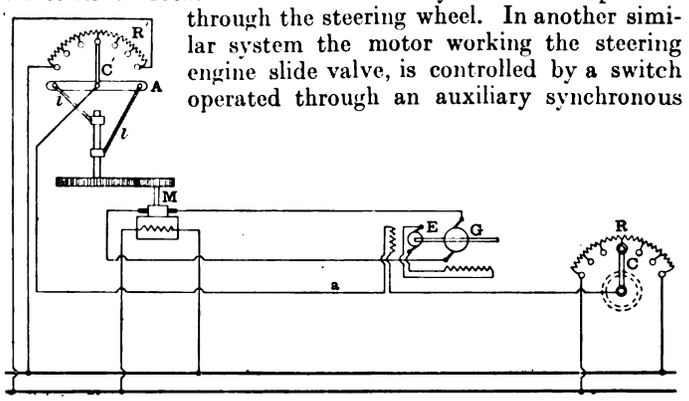

FIG. 3.—PFATISCHER ELECTRIC STEERING GEAR.

three-phase motor in the wheel house. The field of this motor is excited by current developed from a small three-phase machine coupled through gearing to the slide-valve motor, this machine being supplied by direct current from the ship's main circuit and delivering three-phase current to the auxiliary motor by means of three slip-rings. The auxiliary motor and the slide valve motor must therefore always work in synchronism.

Coming to the more interesting problem of the direct control of the rudder by means of electric motors, we find there are several questions which raise substantial difficulties in the case of electrically-operated gears. Taking, as before, synchronous movement of the steering wheel and rudder and reliability as the criterion of success, electricity has no easy

Digitized by Google

task to improve upon steam steering gears, though, as previously mentioned, there are other advantages. Further important points to be kept in view in designing electrical arrangements for operating the rudder are the desirable minimum of complication, ease and rapidity of control, besides, of course, cheapness, lightness and excellence of construction of the motors and gear. It might be thought that for this type of work series motors, with their high starting torque, would be applicable, but, as a matter of fact, they are practically never used, since the pressure of water on the surface of a rudder varies approximately as the square of the sine of the angle of the rudder with the length of the ship; hence the speed of the motor for equal torque, good efficiency and effective operation should vary inversely as the square of the sine of the angle—that is to say, the nearer the rudder is to the centre line the higher should be the speed of the motor, and it is usually attempted to fulfil this condition.

One of the earliest systems is that shown diagrammatically in Fig. 2, this being a construction adopted by the Union Electricitäts Gesellschaft before its amalgamation with the A.E.G. for a Russian cruiser and a German warship. There are two exactly similar motors mounted on the same bed-plate

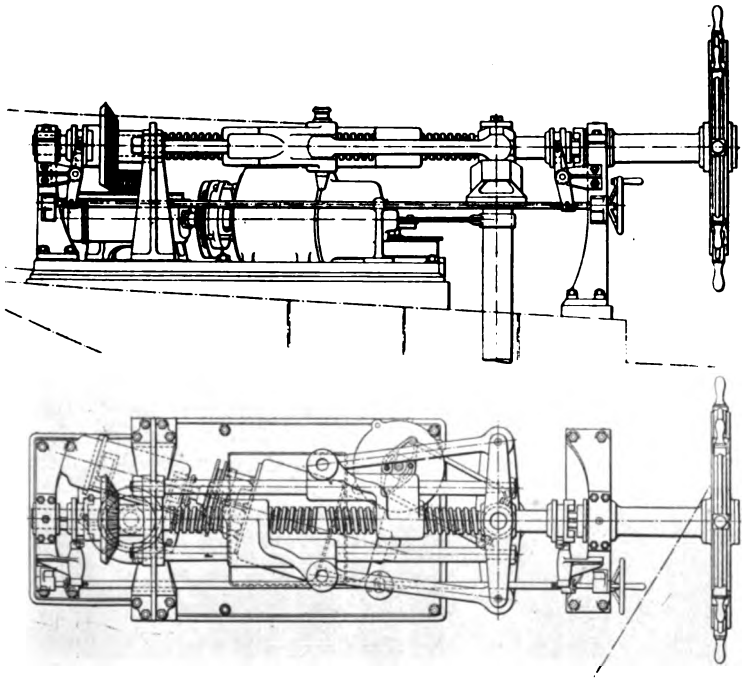

FIG. 4.—GENERAL ARRANGEMENT OF COMBINED ELECTRIC AND HAND STEERING GEAR. (CLARKE, CHAPMAN & CO.)
(Scale 1 : 40.)

with a gear-box between, containing a differential gear by means of which a shaft revolving inside the shafts of the armatures of the two machines is caused to rotate. This inner shaft has a spur wheel keyed on at one outer end, and by means of bevel and worm gearing operates the rudder. When the two motors are running at exactly the same speed there is no tendency for the interior shaft to revolve, but any slight alteration in the speed of one of them causes it to rotate in one direction or the other. As is seen from Fig. 2, the control is obtained by the switch S operated in the navigating house, and the resistance R′ can either be put in parallel with F, the field of the motor M, or with F′, thus causing an increase of speed in the motor with whose field it is in parrallel, being M, as shown in the diagram. The arrangement can be very substantially constructed, but it possesses the inherent defect that it is impossible to rely absolutely on the motors running at exactly the same speed, so that slight movement of the rudder often occurs when it is not desired, and on the whole it is probable that the system will not receive wide application.

An arrangement which has had much success is an American one designed by Pfatischer, and this is in use on several American and Russian ships. It is shown in diagram in Fig. 3. G is a generator driven by a steam engine or other means, an exciter, E, being mounted on the same shaft, delivering its current direct to the field of the generator, whose output therefore depends directly on the power developed by the exciter, which in turn depends on the strength of its own field. This is excited by the current flowing in the wire *a* and only exists when the contact arm C, operated by the steering wheel is in a different position relative to the stops of its rheostat R, from the arm C′, connected to the rudder arm as shown, relative to its rheostat R′, since the rheostats form a Wheatstone bridge arrangement, with *a* as the connection between the arms. The generator G delivers its power direct to the motor M, which operates the rudder through spur gearing, driving a screwed shaft which turns the arm by means of right and left-handed nuts with links, *e*. Though the connections seem complicated, the operation is very simple and exact, a movement of the arm C causing E to be excited and the generator to deliver power to the motor, which continues to revolve until the contact arm C′ reaches a corresponding position to that of C.

An electrically operated steering gear was installed by Messrs. Siemens Bros. on the "Manxman," the ordinary steam steering engine being also employed so that either means could be used. A series-wound motor was employed for operating the rudder, and the control was obtained by a set of relays operated from the bridge, by means of which resistance was put in or out, the arrangement being similar to that which has been adopted in some instances for traction purposes. The relays were not operated direct from the bridge, but two synchronous motors were used, as explained previously, the one in the steering room serving the double purpose of controlling the slide valve of the steering engine when in use, and working the relays of the rudder motor controller. Magnetic blow-outs were employed to prevent dangerous sparking in the controller. The arrangement is unique, and in many ways most interesting, but its complication and the employment of series motors, with the attendant disadvantages, do not warrant any expectation of its extended use.

In an Italian system which has been brought forward within the last few years the principle of the Wheatstone bridge is again employed for producing the synchronous operation of the rudder and steering wheel, as in the Pfatischer arrangement; the rudder motor, however, is not controlled by a separate generator, but takes its power direct from the ship's mains, being controlled by resistances operated by relays in a very ingenious manner. There are several relays, the windings of which are in series with the armature of the rudder motor, and as the speed of this rises, the back E.M.F. increases and operates the relays one after another, thus short-circuiting the resistances until all are cut out. The arrangement is very original, but the necessity of relays is disadvantageous at sea and the system will probably only be adopted in small boats.

The Russian cruiser "Rurik," built by Vickers, Sons & Maxim, in 1907, was fitted with both electric and steam steering gear, either of which could be used as desired. The electric motor operating the rudder was series wound, and current was supplied to it from a motor generator situated in the steering room, this current being controlled by varying the excitation of the generator by means of a rotary rheostat operated from the steering motor itself. Two small synchronous motors, as previously described, were employed to produce synchronous motion of the rudder and steering wheel, the same arrangement being also used to work the slide valve of the steam steering engine. The direction of rotation of the steering motor was reversed by means of a rotary switch on the same shaft as the controlling rheostat, but the adoption of a series motor, and the necessity of switches breaking heavy currents are disadvantages which weigh heavily against the system.

Messrs. Clarke, Chapman & Co., of Gateshead, are the constructors of an electric steering gear which has now been in use for several years with considerable satisfaction, and their arrangement is illustrated in Fig. 4 and a general view is shown

Digitized by Google

in Fig. 5. With this type of gear a head is fitted to the top of the rudder post with two arms, each of which is connected by a connecting rod to a nut on the right and left-handed screw shown in the figure, so that when this screw is rotated the rudder is turned.

This is a usual type of gear and has simply been adapted in this particular case to electric driving by fitting at one end a

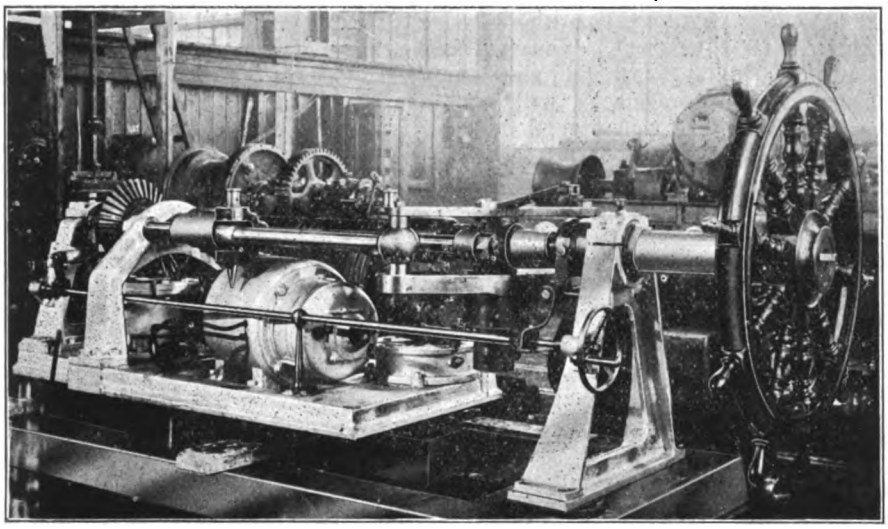

FIG. 5.—CLARKE, CHAPMAN & CO.'S ELECTRIC STEERING GEAR.

pair of bevel wheels, one of which is keyed to the shaft of a worm wheel enclosed in a case shown below the main screw and driven through the worm gear by the motor. Messrs. Clarke, Chapman are also prepared to fit steering gears with "following up" gear, so that when the steering wheel is turned the steering gear will be started, and will automatically stop when the rudder reaches the desired angle.

It will be seen that there are two claw clutches operated by a hand-wheel, the purpose of this being to connect the main screw either to the bevel wheel at the one end for driving by the motor, or to the hand-wheel at the other end, for driving by hand in case of emergency.

The small round box fitted on the bedplate of the gear under

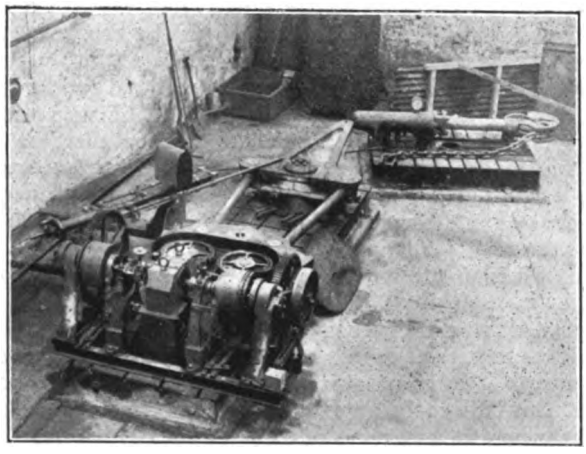

FIG. 6.—BROWN-HAIGH STEERING GEAR AND TESTING ARRANGEMENT.

the hand-wheel end and connected to the rudder post by two small connecting rods, is the transmitting apparatus of a helm indicator to indicate the position of the rudder, on the bridge.

An interesting steering gear has recently been designed and built by Messrs. Brown Bros. & Co. (Ltd.) in conjunction with Mr. B. P. Haigh, of Glasgow University, whose patents are embodied. The gear is illustrated in Figs. 6 and 7, and has been running very successfully at the Rosebank Ironworks, Edinburgh, for several months past. The general view also shows the hydraulic cylinder by which the steering gear can be tested at normal loads and also at heavy and jerky overloads. The design has several novel mechanical features which render it specially suitable for a mechanical drive, and notably a variable leverage link gear, which enables an increased effort to be applied to the tiller crosshead when hard over and at the same time increase the normal speed of working within the range near the midships position. The toothed sector is driven by right and left-hand worm gear, a speciality of this firm, which allows the usual thrust block to be dispensed with, and considerably increases the efficiency of the gear. The current demand from the ship's generating plant is therefore very moderate, even on the rare occasions when the rudder must be put hard over at full speed. The motor is kept running continuously and the gear is started and stopped by magnetic friction clutches on the motor shaft. In this way the sudden peaks of current which are so undesirable in a lighting installation, are entirely eliminated, and the minimum of working switchgear is required. The clutches are controlled by one of Messrs. Brown's new hydraulic standard telemotors, and the whole of the switchgear is, in fact, contained in the small controller mounted above the telemotor receiving gear. It will also be noted that the clutches are built with considerable weight, and are mounted directly at each end of the motor shaft, so that no gearing is in motion except when the rudder is actually being moved. A very desirable result of the use of these clutches is that when the wave-pressure on the rudder exceeds a certain overload, the clutches slip momentarily and thus protect the electrical system.

Very satisfactory results have also been obtained from preliminary tests on a Haigh patent electrical telemotor, by which the motions of the hand-wheel on the bridge are exactly copied by the receiving apparatus in the steering house aft. This result is obtained in a very simple manner by the use of two induction motors, without any working switchgear, and full reliability is claimed. Alternating-current to supply this telemotor is obtained from slip-rings fitted to the main steering motor in the case of the Brown-Haigh steering gear described

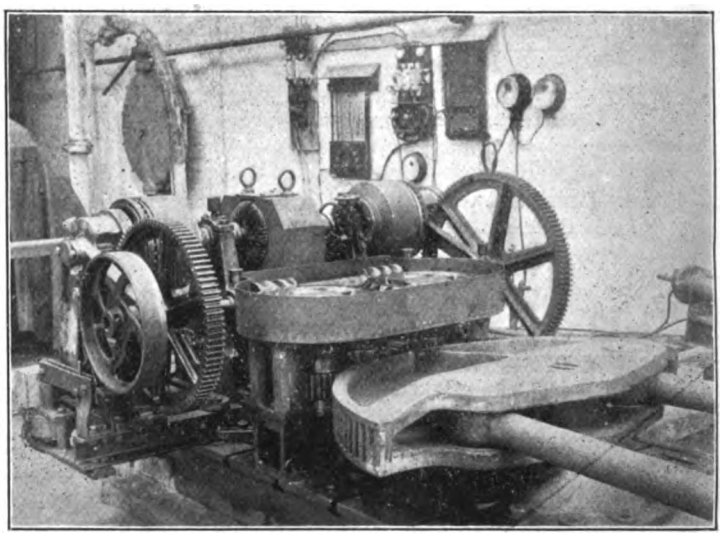

FIG. 7.—GENERAL VIEW OF BROWN-HAIGH STEERING GEAR.

above; but a three-phase system is preferred as the main steering motor can then be of the simpler squirrel cage type.

There are a number of other methods now in use or about to be tried, but they all bear some resemblance to one or other of those already described. There are such obvious advantages in the employment of electricity for steering that very marked progress may be expected in this direction in the near future, and this is all the more probable in view of the present tendency to replace all steam auxiliaries on ships by electrical machinery, which is advisable both from the standpoint of efficiency and simplicity of operation.

Electric Helm Indicators.

The object of the helm indicator is to show on dials on the bridge or other positions in a vessel the angle of the rudder.

The Richards-Evershed system of helm indicators, which has been in use for many years in the British and other Navies, depends for its action upon the movement of a soft iron needle freely pivoted at the centre of two coils whose axes lie at right angles to one another. The position of the needle, of course, depends upon the ratio of the currents flowing in the two coils.

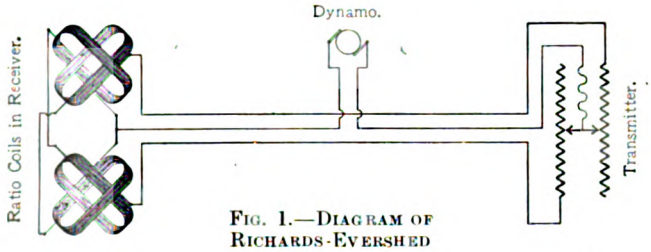

FIG. 1.—DIAGRAM OF RICHARDS-EVERSHED SYSTEM.

In the earlier form of this apparatus the ratio of the currents was altered by sliding a contact on a resistance. In 1906, however, an improved design was adopted. This is illustrated diagrammatically in Fig. 1, from which it will be seen that resistance is added to one circuit and removed from the other. The general arrangement of the Indicator is shown in Fig. 2. Two soft iron needles are used, each in a separate pair of coils; they are linked together by a light coupling rod, which transmits their motion to the indicating pointer. The coil system is duplicated, and the current is passed through corresponding coils in opposite directions, in order that the system shall have as little external field as possible; and what little effect remains is neutralised by an automatic compensator fixed in the upper part of the instrument. This is merely an electro-magnet energised by the current, so that its field varies with that of the coils; and its size and position have been determined by experiment, so as accurately to compensate for the external field of the coils.

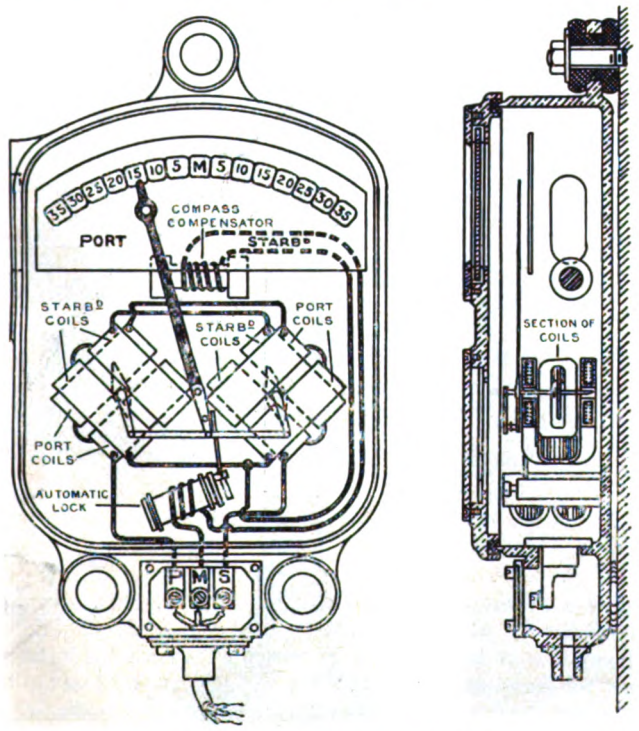

FIG. 2.—GENERAL ARRANGEMENT OF HELM INDICATOR (1906 PATTERN).

The dial of the indicator has a scale divided at every 5 deg. of helm, corresponding to the motion of the contact arm in the transmitter over the contacts in the transmitter switches, which are spaced 5 deg. apart. The bridging of two adjacent contacts by the contact arm causes an intermediate signal, roughly corresponding to 2½ deg. of helm; but no attempt is made to make this indication accurate, except immediately on either side of the 'midships' point. Under the nameplate on the front of the indicator is fitted a device, which enables an accurate adjustment of the pointer to 'midships to be made, by simply turning a screw, which, by means of an eccentric, gives a limited sideways motion to the axis of the pointer.

It should be noted that these indicators are now made universally interchangeable, provided, of course, that they are wound for the same voltage. The utmost possible care is also taken to render the instrument absolutely watertight, a point of extreme importance; and the terminals are therefore placed in an external terminal box so that the instrument may be coupled up without opening the inner case. Provision is also made for a lamp which can be fixed outside the case when it is necessary to provide an illuminated dial.

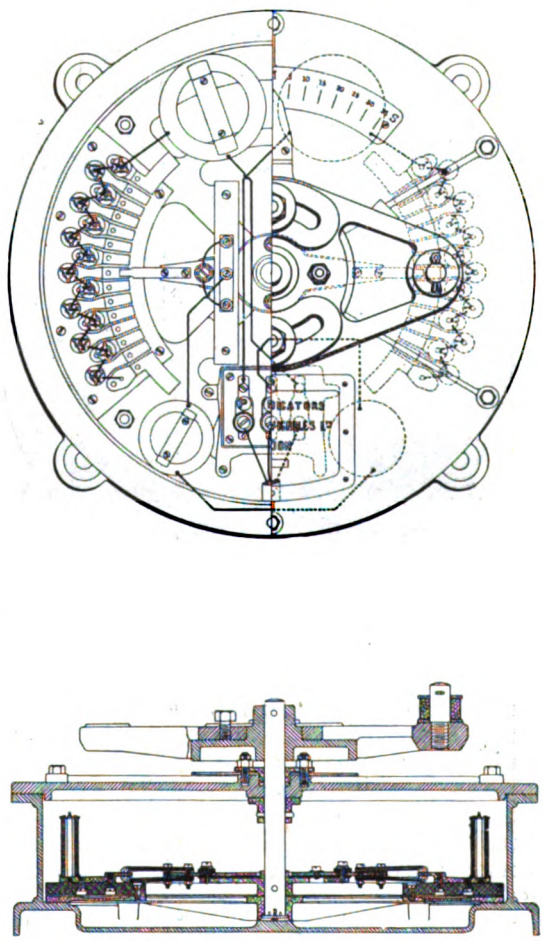

FIG. 3.—GENERAL ARRANGEMENT OF AUTOMATIC TRANSMITTER.

The general arrangement of the transmitter is shown in Fig. 3. The resistance is distributed on china bobbins mounted on the switch contacts, and the connecting switch arm is attached to the central spindle, whose motion is determined by the rods which connect it through a cross-head to the rudder-stock. The arrangement of the cross-head and rods is clearly shown in the view of the transmitter given in Fig. 4, which also illustrates the arrangements adopted for the relative adjustment of the coupling rods and transmitter spindle to secure an accurate adjustment at 'midships when the transmitter is being fitted in the ship. The connections for the transmitter are made under the name plate shown in Fig. 4, a rubber joint being provided to

Digitized by Google

secure that the instrument shall be watertight after the plate is screwed down.

In nearly all ships two or more indicators are provided, provision being made for coupling any one of the indicators to the transmitter. The whole of the transmission is effected by one three-core cable.

Fig. 5 shows the simple manner in which the system can be applied to provide a complete system for transmitting orders and receiving a reply, by the addition of one wire only. In such an arrangement as this the indicator and the transmitter are combined in the same case.

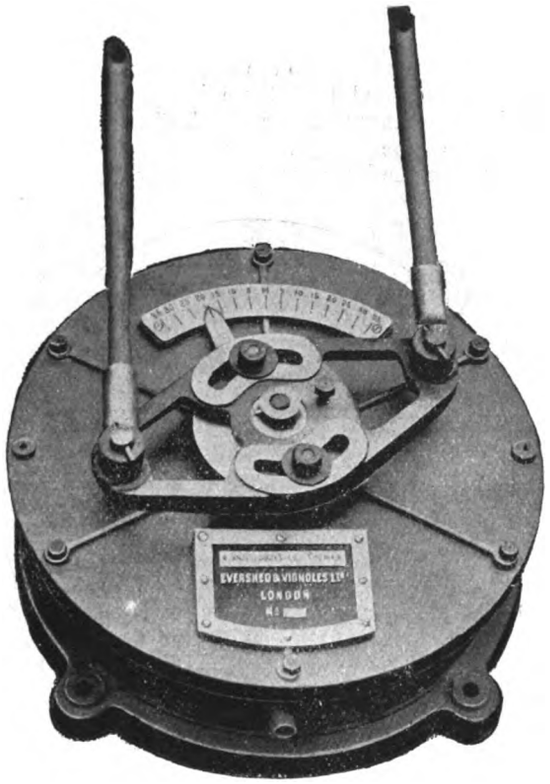

FIG. 4.—VIEW OF RICHARDS-EVERSHED TRANSMITTER.

The electric helm indicator, made by Messrs. Siemens Bros & Co., consists of a transmitter situated near the rudder stock, and connected to it by means of a pulley and special driving gear, and in electric connection, by means of a four-core cable, with any number of indicators or receivers placed where required. The transmitter is a form of switch or contact maker, which sends current to a group of magnets in the receivers and causes their armatures to revolve and move the pointers in such a manner that these take up positions corresponding with that of the rudder.

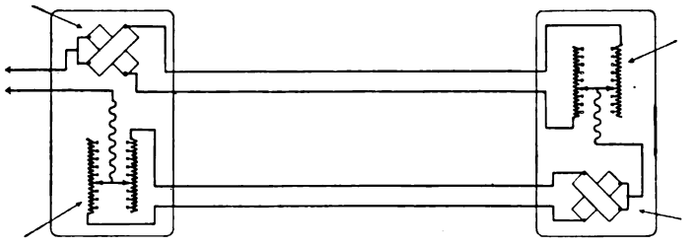

FIG. 5.—DIAGRAM SHOWING ARRANGEMENT WITH REPLY TRANSMITTER AND INDICATOR AT EACH STATION COMBINED IN ONE CASE, FOUR WIRES ONLY BETWEEN STATIONS.

The driving gear, by means of which the transmitter is connected to the rudder, consists of a grooved pulley clamped on to the rudder stock. To the latter are fastened flexible steel wire ropes connected by special spiral spring couplings to lengths of roller chains driving toothed wheels on the spindle of the transmitting switch. These spring couplings are provided to allow a certain movement of the rudder before the switch is actuated. This, together with a form of escapement gear, ensures that the movement of the switch is definite from one set of contacts to another, thus avoiding sparking and other contact troubles. Two sets of ropes, springs and chains are provided, either set being sufficient to do the driving of the switch.

The switch is contained in a gunmetal case provided with a watertight cover and separate terminal box, and mounted on a brass column, the height of which is arranged to suit the particular type of steering gear. All parts are very accessible and of substantial construction.

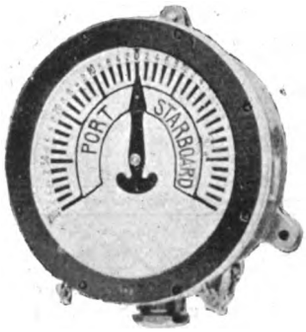

FIG. 6.—SIEMENS HELM INDICATOR "RECEIVER."

The indicator or receiver (*see* Fig. 6) is a dial instrument, and consists of a gunmetal case with a watertight front fitted with plate glass. It contains the magnetic motor for actuating the pointer. The dial over which the pointer moves is of opal

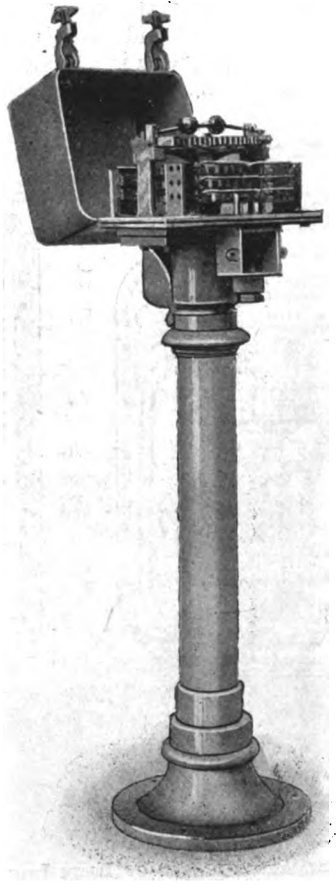

FIG. 7.—SIEMENS HELM INDICATOR "TRANSMITTER."

glass for purposes of internal illumination, and has on its surface the scale for indicating the movement of the rudder in degrees. The scale is of a very open and bold character, and embraces an angle of 120 deg. from "amidship" to "hard over."

The transmitter switch (*see* Fig. 7) consists of four rings, one of which is continuous and forms the feeder to the other three,

Digitized by Google

which alternately make contact as the switch is revolved to the three pairs of magnet coils of the magnetic motor. The motor consists of three pairs of magnets, between the poles of which are mounted two armatures, one at each end, both carried on one spindle, on the end of which is fixed a small worm for actuating the spindle, which carries the pointer of the receiver.

The internal illumination is provided by a lamp, provided with a special watertight fitting which enables it to be readily removed and which makes contact to the terminals of the lamp when placed in position. The indicator case is provided with lugs for fixing to a bulkhead or other support, and has a polished front, and is fitted with watertight cable glands. It can also be provided mounted on a column. It should be noted that any number of receivers can be actuated at the same time from the one transmitter.

Revolution Indicators.

In marine work it is highly necessary that the number of revolutions of the main engines should be indicated continuously on the bridge. Several arrangements have been proposed for doing this, and we may be forgiven for recommending an electrical one, such as that made by Messrs. Siemens Bros. & Co.

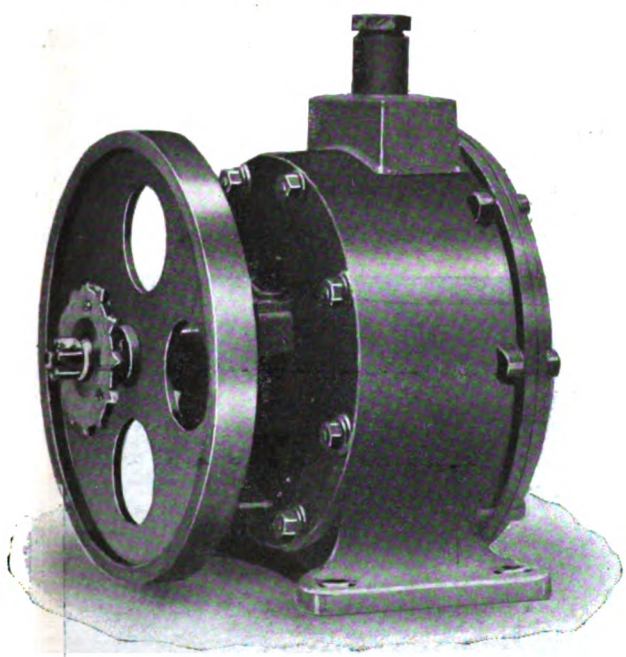

FIG. 1.—TRANSMITTER.

This apparatus is used for indicating the speed in revolutions per minute of an engine or other shaft, at positions situated at a distance from the shaft. It offers, it is claimed, many other advantages over all other types designed for the same purpose, and embodies several features which make it eminently suitable for indicating on the bridge of a vessel the speed at which the engines are running.

The method of transmission is by alternating current, supplied by a special form of generator driven by chain gearing from the engine shaft, the indicators or receivers being voltmeters constructed on the well-known "Ferraris" principle. The transmitter is constructed so that the voltage generated is proportional to the speed, a result obtained by employing a fixed armature and revolving a magnetic field composed of permanent steel magnets. This method does away with the necessity of slip rings and contact brushes, which are liable to introduce errors due to wear taking place with a consequent alteration of the points of contact, and also to variation of the resistance of the contact surfaces, causing a difference voltage.

The Ferraris voltmeter, which forms the receiver or indicator, is the most accurate form of alternating-current voltmeter, and has the additional advantage of having a scale which subtends about 280 deg. permitting of large and open divisions. The zero is in the middle position, and the pointer moves to the right or the left, according to the direction of rotation of the shaft. The turning force of this type of instrument is very great, by reason of which the pivots and other moving parts can be of substantial construction.

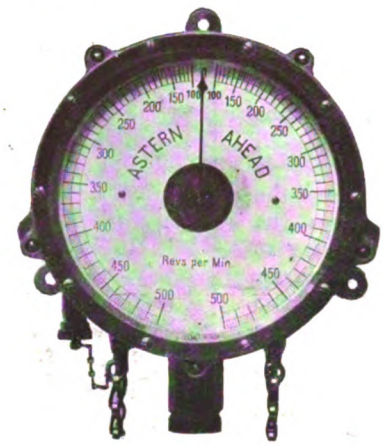

FIG. 2.—INDICATOR.

The transmitter, Fig. 1, is of water-tight construction, with very efficient lubrication to the revolving spindle. For turbine-driven shafts, where the turning movement is uniform during a revolution, the chain drive is direct from the engine shaft but for reciprocating engines the drive takes place through a regulator, to ensure the speed of the transmitter keeping regular during a revolution. A flywheel is added to assist this. The regulator is a form of spring coupling, arranged as a countershaft, which is driven by a chain from the engine shaft, and to which the transmitter is connected by a chain drive. The receiver or indicator (Fig. 2) is contained in a water-tight case, provided with lugs for fixing to a bulkhead or other support. Arrangements for illumination are provided when required.

Battery-Booster Plants on Rapidly Fluctuating Loads.

Some remarkable economies have been effected by the installation of a battery and reversible booster in cases where heavy fluctuations occur on the generating plant, as, for instance, a crane load or the electrical equipment of a steel works or shipbuilding yard. It is, of course, necessary that the booster used in connection with this class of work should be instantly reversible and capable of coping with the heavy fluctuations that occur without any adjustments being necessary as the load varies and the state of charge of the battery alters.

The "Entz" booster, supplied by the Chloride Electrical Storage Co., is controlled by the operation of a carbon regulator consisting of two sets of piles of carbon discs, a lever being pivoted between the two sets, from one end of which is freely suspended a soft iron core surrounded by a solenoid carrying the entire generator load. To the other end of the lever is attached a spiral spring, the tension of which is regulated to counterbalance the pull of the solenoid. This enables any predetermined load to be allotted to the generator. Variations in the total load above or below this fixed generator load will cause changes in the pressure on the carbon piles, resulting in

Digitized by Google

a wide variation of their contact resistance, which will affect the field excitation of the booster through the intermediary of a small exciter, the field of which is controlled by the current passing through the carbon regulator. When the desired average load is on the generator the pull of the solenoid and the spring counterbalance each other, and as then the resistance of the carbon piles is equal, the booster field coil is not excited. Should however, the line load rise above the average, so that the load on the generator tends to increase, the pull due to the increase in current flowing round the solenoid overcomes the tension of the spring at the other end of the lever. This action compresses the carbon piles on one side and allows the current to flow in the field of the exciter in a direction which will energise the booster field coil in such a manner as to add to the voltage of the battery and cause it to discharge. If the load should fall below the average the generator output will tend to drop, and the spring at one end of the lever of the carbon regulator will overcome the pull of the solenoid. The carbon piles of the regulator (on the other side to those which were compressed when the battery was discharged) will then be compressed, and the battery will receive a charge equal to the difference between the average generator load and the line load.

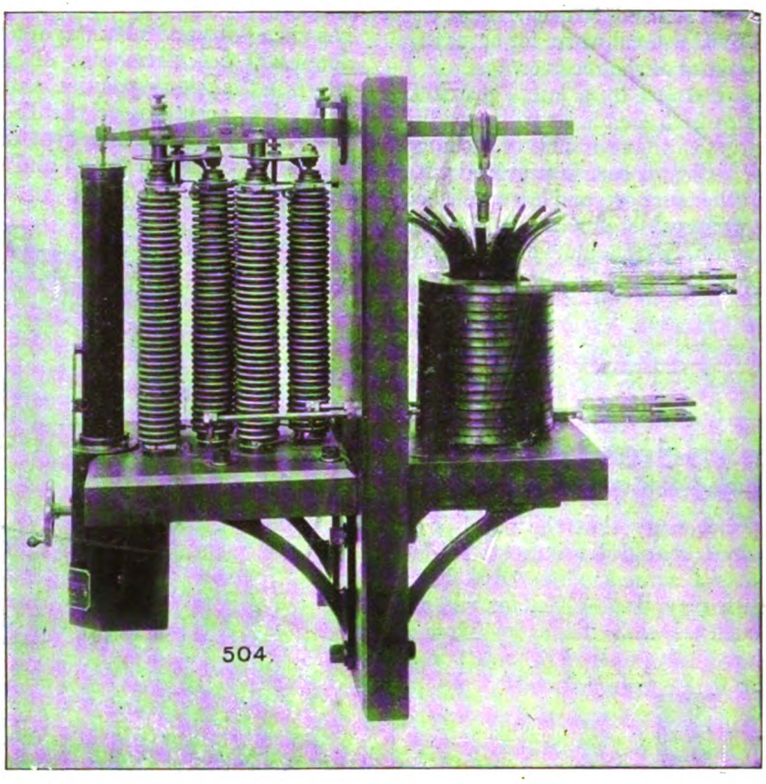

FIG. 1.—VIEW OF ENTZ REGULATOR.

The load to be taken by the generator may be adjusted to any desired amount by varying the tension of the spring at the end of the lever which regulates the pressure on the carbon piles. This adjustment is instantly made by a small hand-wheel, and may be altered from time to time to meet any considerable changes in the nature of the load, so that the battery can be either floating, giving a continuous peak discharge, or being charged according to the adjustment, while at the same time it will always automatically take the momentary fluctuations of the load.

An interesting application of the "Entz" booster is afforded by a plant installed at a steel works in Scotland. At the time when this plant was laid down the generating plant consisted of two 375 kw., 20 to 230 volt high-speed direct-coupled steam sets. As about 70 per cent. of the motors installed are series-wound, the starting currents are very heavy, with the result that it was

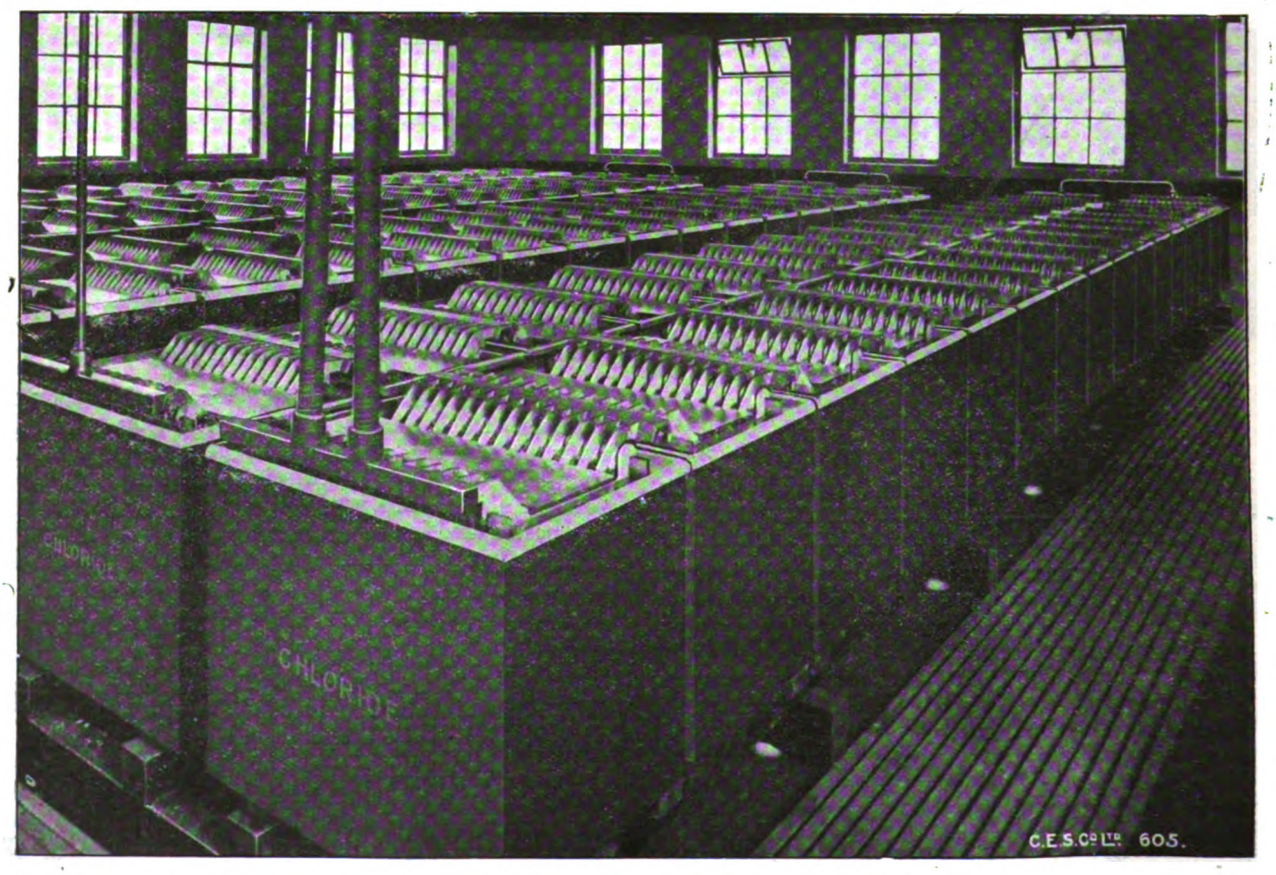

FIG. 2.—BATTERY OF CHLORIDE ACCUMULATORS.

Digitized by Google

occasionally necessary to run both sets, and as new plant is in contemplation it would have necessitated both sets running continuously.

It was decided to employ a battery-booster plant to relieve the generating plant of the peaks of the load, and a battery of 114 cells was installed, capable of discharging at the rate of 1,190 amperes for 1 hour, together with a booster to control the charge and discharge of the battery. Any increase in the load, above the mean load, is now automatically thrown on the battery by the action of the carbon regulator which controls the booster, and in the same way any decrease in the load, below the mean load, is automatically compensated for by the carbon regulator causing the booster to charge the battery and so maintain the load on the generating plant practically constant. The net result is that, whereas formerly it was at times necessary to run both steam sets, it was then found that one could deal with the load, resulting in a considerable economy in steam consumption, a reduction at top load of 50 per cent. in the amount of running plant required (one set being thus set free to act as a stand-by), while the battery acts as a further stand-by, and is also available for a source of supply for week-end repairs and lighting. The battery-booster plant is arranged to run in parallel with any set that may be required to meet the average demand.

Since the battery was installed a considerable amount of additional plant has been laid down, involving a large number of motors, of which there are now about 200 installed in the works, with an aggregate of about 4,000 B.H.P. There are eight charging machines, which take from 300 to 400 amperes starting current. The rest of the motors work roller racks, screw-down gear, cranes, pumps, &c. To deal with this increased load, a steam turbine set was installed of 500 kw. capacity, and it is found that this set, together with the battery, is able to deal with the whole electrical requirements of the works.

The various economies brought about by this combination of turbo-generator and battery-booster plant are worth consideration in all cases where a fluctuating load has to be dealt with.

Ship Illumination and Fittings.

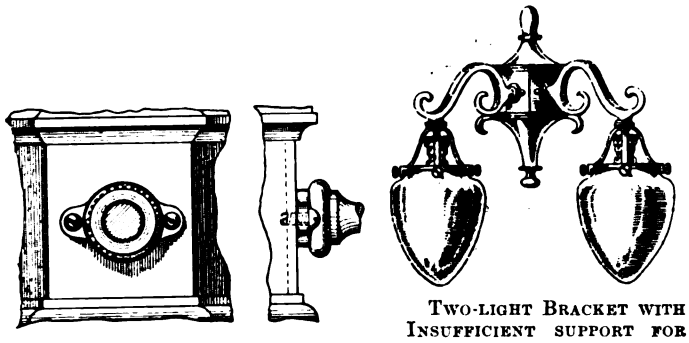
BY G. AUSTIN.

(Of Messrs. W. C. Martin & Co.)

Summary.—The author discusses the character of lighting and fittings suitable for decks, cargo holds, cattle spaces, emigrant accommodation seamen's and officers' quarters, passengers' cabins, dining saloons, lounges, drawing rooms and smoking rooms, signal lamps and navigation lamp indicator. It is necessary that particular attention should be paid to insulation and the prevention of trouble by vibration.

Among the endless variety of electric lamp fittings on the market only a small proportion is suitable for use on board ship. The demand for flexible pendants and flexible drops on brackets and electroliers, which has been the fashion for some years, makes the proportion available still smaller.

But even the majority of brackets and electroliers made with rigid arms for use on land would be quite unsuitable if fitted on board-ship. Ship fittings must be strong and well put together in order to withstand the vibration and rough handling to which they are exposed. A frequent source of weakness is to be found, for example, in bracket fittings where the arms are fastened to the backplate. One often finds long slender bracket arms screwed into a very thin plate, with nothing to prevent the arms from turning round, or the arms are frequently fastened to the base plate by a tiny flange and two small screws. The small flange referred to is often fixed as shown in Fig. 1, and there is no adequate means for supporting the weight of the bracket arms, so that the small screws soon lose what hold



DETAIL OF FAULTY CONSTRUCTION AT BASE OF BRACKET ARMS.

TWO-LIGHT BRACKET WITH INSUFFICIENT SUPPORT FOR BRACKET ARMS AND FAULTY GLOBE HOLDER.

FIG. 1.

they have of the base plate, and the inevitable result follows. Fittings of this kind, if chosen for ship use, must be altered and strengthened, or failure is certain.

In view of these defects and the exceptional conditions prevailing on board ship, the writer proposes to deal with the illumination of each part of a passenger and cargo steamer separately, and at the same time to describe the most suitable fittings for each section.

Cargo Fittings.—While loading or discharging cargo from a vessel at night it is advisable to have the decks and cargo spaces properly lighted. For deck lighting, arc lamps were tried many years ago, the lamps being suspended from the rigging, but they did not prove so successful as was expected and were soon discarded. There were many reasons for their want of success. The lamp mechanism was affected by vibration, and the light often flickered when the winches were used, just when light was most required. In those days arc lamps were invariably made having the return circuit through the lamp case, and trouble resulted when the lamp case came in contact with a wire stay or wire rope, to say nothing of the shocks experienced by seamen and others. Perhaps the greatest drawback was that the carbons only lasted eight hours, and the engineer had often to be roused in the early hours of the morning to trim the lamps.

But now these drawbacks have all been overcome. There are many excellent makes of arc lamps on the market which maintain a steady illumination under very severe vibration, and in which the lamp case is entirely insulated from the circuit. Arc lamps are now extensively used for lighting cargo decks in port, and the 1,000 watt enclosed arc is a great favourite. Instead of outer globes, octagonal lanterns with panes of flat obscured glass are preferred, because a broken pane can be easily replaced in any port. For most cargo ships two arc lamps are sufficient, one at the foremast and one at the aftmast.

In addition to the arc lamps, clusters of incandescent lamps are always provided at each cargo hatch, also at coaling ports and at the stern of vessel for use when repairing propellers.

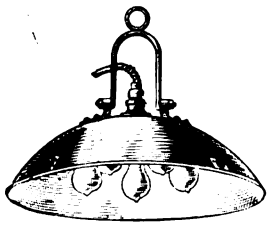


FIG. 2.—CLUSTER WITH FAULTY CABLE ENTRANCE.

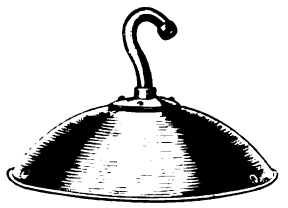

FIG. 3.—CLUSTER WITH APPROVED CABLE ENTRANCE.

Figs. 2 and 3 show two forms of cluster commonly used, each similar in general appearance, yet differing in one important detail. In Fig. 2 it will be noticed that the flexible cable enters by a grip gland on top. Water is not only likely to get into the connections at this gland, unless it is very carefully packed, but the flexible cable will always be bent sharply at this point and pulled in so many ways that it is apt to be injured. In Fig. 3, on the other hand, the flexible cable is led in a downward direction by the leading-in tube, and water falling on the shade cannot enter the fitting.

These cargo shades are hung in the corners of hatches or on railings, or in some cases over the side of the ship to give light

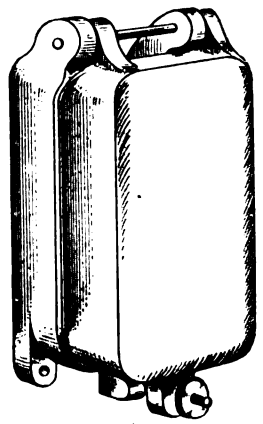

FIG. 4.—CAST-IRON WATERTIGHT CONNECTION BOX.

FIG. 5.—HOLD FITTING.

to barges. Clusters are sometimes used in cargo spaces, and in such cases it is usual to fit permanent sockets in strong iron boxes near the hatches. Fig. 4 shows a serviceable box of this kind, which is suitable and very strong.

Portable plug connections should be constructed to receive a flexible sleeve, one end of which is bound to the plug and the other end to the flexible cable. These sleeves may be made of leather or rubber, or built of whalebone bound with tape and cord. Connection boxes for use on deck must be thoroughly

Digitized by Google

watertight, but in any case it is preferable to fit these in sheltered positions.

Hold Lights.—It is not usual to fit many lights in cargo holds, six or eight lights being generally considered sufficient. They must be placed in positions where they are naturally protected by beams or other structures, because any guard that may be on the fitting itself cannot possibly be made strong enough to withstand heavy knocks from cases and bales of cargo, and at the same time allow sufficient light to pass. There are, therefore, two kinds of fittings used for cargo spaces, those in which the lamp is protected by a strong metal guard of rectangular cross-section, as shown in Fig. 5, and those in which the light is covered, when not in use, by a solid metal cover, as shown in Figs. 6 and 7. The covers in the latter patterns are held up by strong T shaped catches when the lights are in use. In

FIG. 6.—CATTLE OR HOLD FITTING.

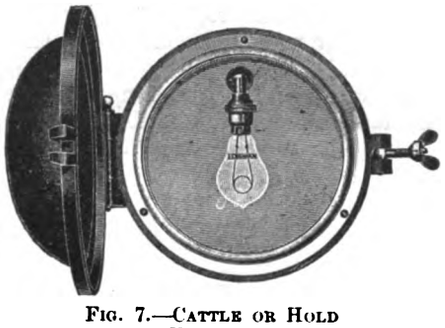

FIG. 7.—CATTLE OR HOLD FITTING.

fittings of this type, also, the lamp glasses are exposed while the lights are in use, and the shutters are apt to be broken at the hinge. In spaces where cotton and bales of soft goods are stowed, the pattern shown in Fig. 5 is most suitable. The bales are pressed into position by screw jacks, and any obstruction is easily carried away. The guard on Fig. 5, however, diverts the bale sufficiently to prevent damage to the lamp. Indeed, for general cargo purposes, this style of fitting is very successful. Lights in cargo spaces should not be placed in positions where they are likely to be blocked up by cargo built in front of them.

Cattle Spaces are lighted by lamps placed in the passages from 24 ft. to 30 ft. apart, and here the patterns shown in Figs. 6 and 7 are best suited to the conditions. Nothing short of a

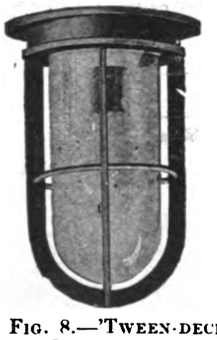

FIG. 8.—'TWEEN-DECK PENDANT.

FIG. 9.—CARGO CAP FOR 'TWEEN-DECK PENDANT.

solid cover will withstand the butt of a bullock's horn, and yet the position of the cover may be so adjusted as to give all the light necessary.

Emigrant Accommodation is often improvised in the upper portion of a cargo hold, called a "'tween-deck," and for this reason the electric lighting must always be fitted in such a manner that the space may be available for either emigrants or cargo, according to the demand. When there is a definite plan arranged for portable rooms, the best method is to fit in each room space, and also in passage spaces, an electric light fitting as shown in Fig. 8. When cargo is to be carried, the lamps and guards are removed and a metal cap, as shown in Fig. 9, takes the place of the guard and protects the lamp-holder from damage. Sockets may also be fitted at each lamp fitting in series with the lamp for inserting portable switches if required.

When a definite plan has not been arranged for any emigrant space, it is perhaps best to fit a number of sockets throughout the space for connections to temporary wiring or portable lights.

Deck Lights are usually fitted from 20 ft. to 30 ft. apart, according to the class of passengers and the nature of the deck space. Deck spaces forward of the navigating bridge are usually left unlighted, because of the glare which would prevent the officers from seeing distant lights effectively.

FIG. 10.—DECK FITTING.

Lights on other decks must also be so arranged that they do not interfere with the navigation of the ship. Probably the best method is to place bulkhead fittings, similar to that shown in Fig. 10, on the deck houses. When lights in this position are objected to, on the plea of interference with navigation, the only alternative is to fit an additional number of lights overhead, so that the direct glare of the light is screened by the deck beams.

FIG. 11.—GUARDED PENDANT.

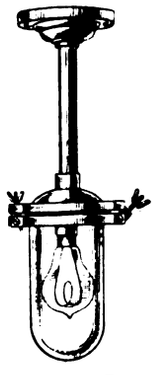

FIG. 12.—DECK PENDANT.

Fittings for use on deck must be watertight, and arranged so that water cannot find its way into the fitting from behind. The best method is to mount the fitting on a metal box with stuffing glands for the entrance of the wires.

The fitting shown in Fig. 11 is not successful as a deck fitting on account of the screw of large diameter necessary for fixing

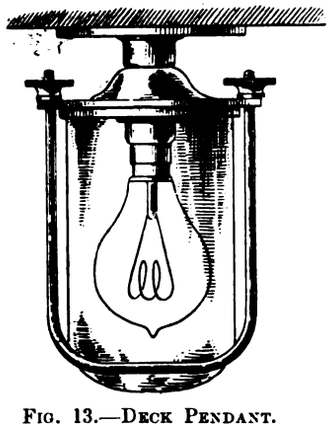

FIG. 13.—DECK PENDANT.

FIG. 14.—OFFICERS' BRACKET.

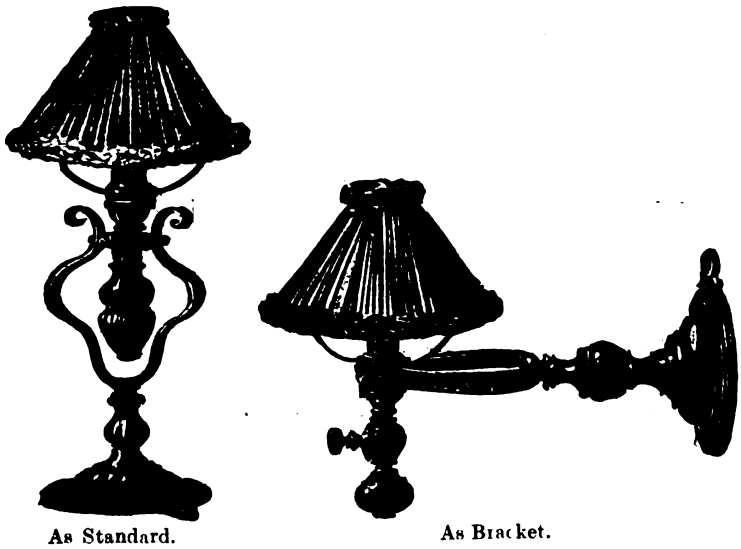
the guard. This screw, unless kept well lubricated, becomes so stiff in a short time that it is often impossible to remove the guard without twisting the stem of the fitting. The fittings shown in Figs. 12 and 13 are more suitable, because the glasses may be removed at any time by unscrewing two small thumb nuts, the threads of which are more easily kept in good order.

Digitized by Google

Seamen's and Firemen's Quarters.—Any of the fittings shown in Figs. 8, 11, 12 and 13 are suitable, the main requirement being that the lamps are protected from breakage by accidental knocks.

Officers' and Engineers' Rooms have usually one fixed and one portable light in each room, and, as a great deal of writing is done here, a bracket lamp fixed over the writing table is most appreciated. Fittings of the same style as fitted in passengers' state rooms are, as a rule, suitable; but the bracket shown in Fig. 14 is a good example of the type preferred. It is strong and serviceable, and gives a well-diffused light. Portable lamps should have a broad and heavy base, and should be fitted with means for placing them on the bulkhead, as a bracket lamp, when not required on the table. Fig. 15 shows a balanced standard in which the lamp is always kept in an upright position by the balance weight shown. The objection to this particular pattern is that, on account of the weight being so high, the fitting is somewhat top heavy, and the base is not broad enough to prevent it falling over in rough weather.

Passengers' Cabins.—A number of fittings, all suitable for use in passengers' cabins, are shown in Fig. 16. There is, of course, no end to the diversity of patterns used, all varying with the class and style of the rooms, or with the taste of those responsible for the choice of fitting; but in the majority of ships a simple and strong fitting of neat appearance is usually preferred. Makers of fittings are slowly coming to realise that a



As Standard. As Bracket.

FIG. 15.—GIMBAL PORTABLE LAMP.

⅜ in. lamp-holder is preferred by ship contractors, but some have not yet learned to make the tubes leading to these lamp-holders large enough to pass two 3/20 insulated wires. One sometimes finds a fitting contracted at some part of the tube to almost ¼ in., usually at a nipple or joint in the tube, when there is really no need for such a reduction.

Another common fault in fittings is that the nipple to which the lamp-holder is screwed is often made so long that, when the holder is screwed home, the end of the nipple presses against the porcelain interior of the lamp-holder.

Perhaps the worst defect in some fittings is the flimsy globe carrier and globe screws fitted. A heavy globe acts, as the ship rolls about, with considerable force, and tends to loosen the connection between globe-holder and stem, and therefore a thin stamping clamped between two nuts is hardly good enough for ship use. The practice also of fitting three small pinching screws, tapped into a thin stamping, cannot be too strongly condemned as an effective globe-holder (*see* Fig. 1). The screw threads strip, as a rule, but even if they did not the screws soon slacken back and the globe falls.

There are two methods of fixing globes in common use, one in which a split ring is slipped between the screw ring and the lip of the globe, and the other in which the globe rests on a tripod suspender, and is held in position by a gallery on top, pressed into position by a small nut on the central stem. Either of these methods makes a very satisfactory job.

Dining Saloons are most effectively lighted by fittings placed on the ceiling over the tables, if regard is to be had to economy. When the design of the ceiling does not lend itself to a proper distribution of lights over the tables, a good plan is to fit a light in each panel or division in such a way that the ceiling is evenly illuminated. Clusters of lights in dining saloons are not so successful as single lights evenly distributed. Another very successful method of lighting a dining saloon is to fit wall brackets round the room, and provide each table with one or

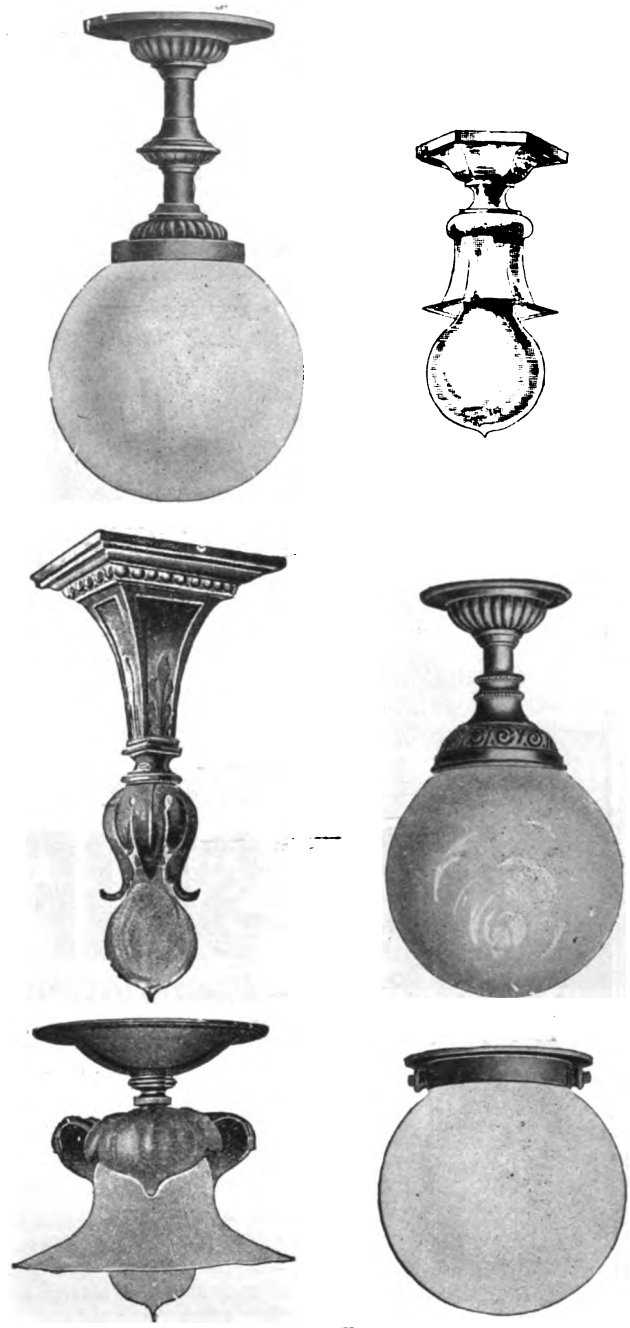


FIG. 16.—CABIN FITTINGS.

more standards with suitable silk shades. In this case no ceiling lights need be fitted, and the effect of the brightly lighted tables in the dimly lighted room is very pleasing.

The number of lamps required to light a dining saloon, besides depending on its size and class, also depends on the height and colour of ceiling and walls, and the density of shades or globes employed for diffusing the light. As a general rule, however, good lighting is obtained by installing one 16 c.p. lamp for each 30 sq. ft. of floor area in the case of first-class saloons, and one 16 c.p. lamp for each 45 sq. ft. in the case of second-class saloons.

Nearly every dining saloon has a well in the centre to give light in the daytime and also to ventilate the saloon, and this well provides a special opportunity for artistic lighting.

FIG. 17.—DINING SALOON FITTINGS.

Fittings suitable for dining saloons are shown in Fig. 17.

Lounges and Drawing Rooms are now frequently built with high ceilings, which enhances their appearance and gives greater scope for displaying fittings. Electroliers of special construction, capable of withstanding vibration, fixed to the ceiling, together with brackets fixed to the wall panels, and a few figure fittings, form the most effective method of lighting these rooms. Indirect lighting by means of concealed lamps reflecting on a white ceiling is not a conspicuous success. The ceiling has to be much over-illuminated in order to provide normal illumination near the floor, while the power required is about four times that necessary with direct lighting.

Owing to the light absorbed in shades, &c., in these rooms it is necessary to allow one 16 c.p. lamp for every 16 sq. ft. to 24 sq. ft. of floor area in the case of first-class rooms, and one 16 c.p. lamp for every 32 sq. ft. to 40 sq. ft. in the case of second-class rooms. Fig. 18 shows fittings suitable for lounges and drawing rooms.

Domes with plaster ornamentation and coloured glass windows, or coloured glass domes supported on wrought-iron grilles, are frequently fitted in lounges, and require special

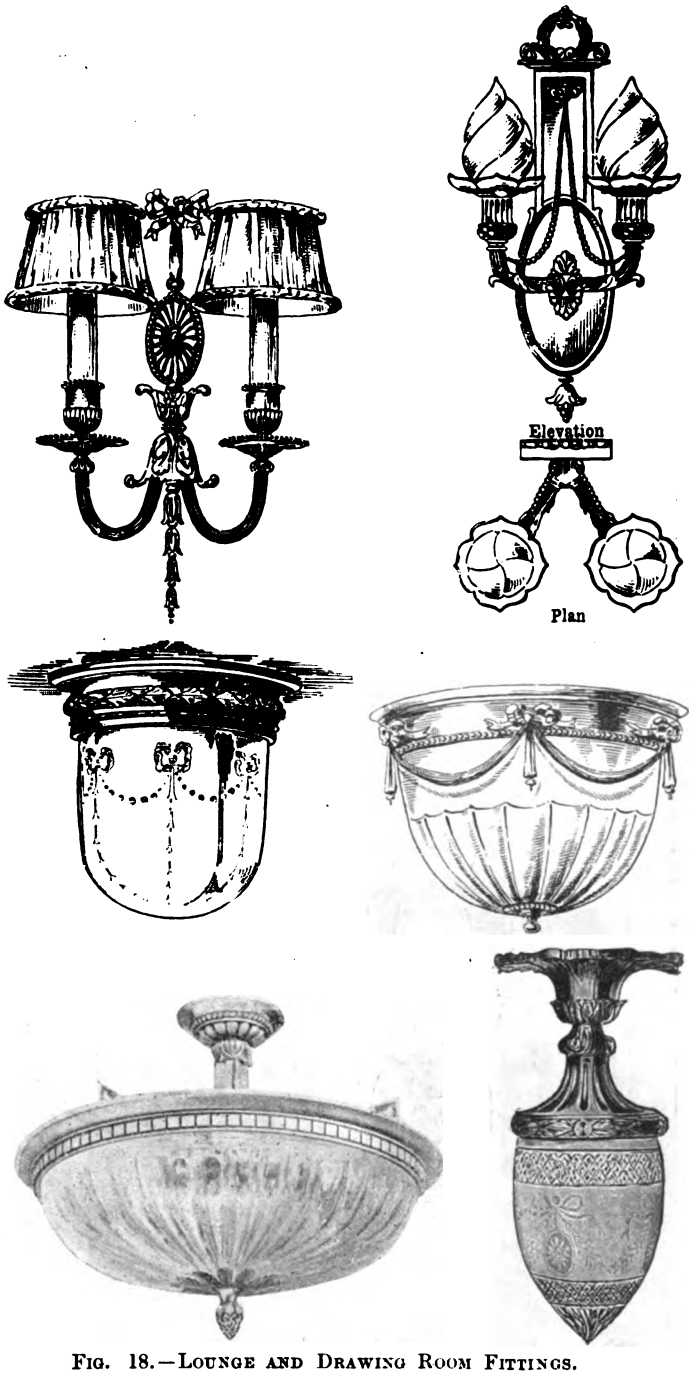

FIG. 18.—LOUNGE AND DRAWING ROOM FITTINGS.

consideration. When plaster work is fitted, perhaps the most successful method of illumination is to fit frosted bulb lamps in small ornamental recesses in the plaster. Certainly the best

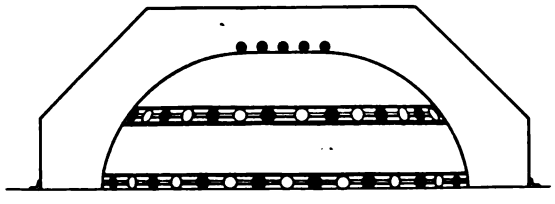

FIG. 19.—ARRANGEMENT OF LIGHTS BEHIND STAINED GLASS DOME. LIGHTS SHOWN THUS: ●

effect from a small number of lamps is obtained in this way. Another method is to fix Linolite lamps in a concealed position at the base of the dome. In this case the light is thrown

Digitized by Google

directly on the objects to be illuminated, and should not be depended on for lighting the area below.

In the case of stained glass domes, a number of small brackets arranged round the base of the dome gives all the light required

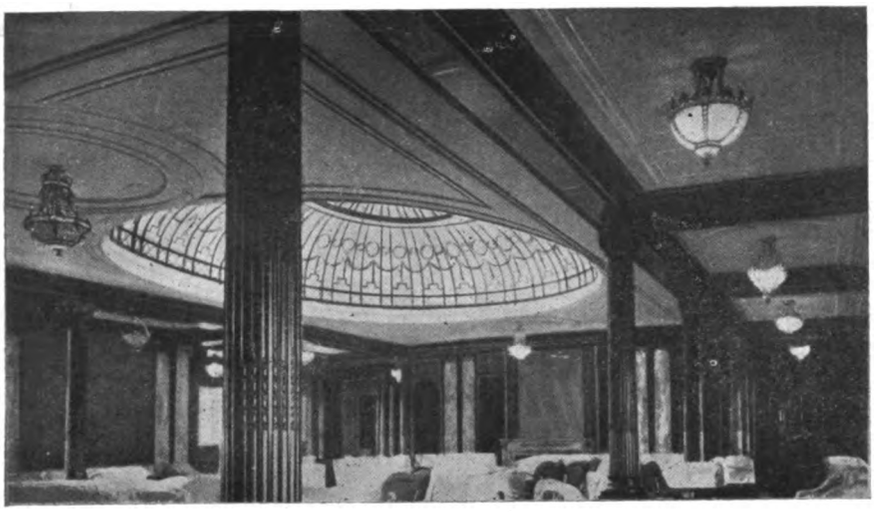

FIG. 20.—DOME OF THE SS. "MAURETANIA" LOUNGE.

at night. The stained glass may be seen and admired in the daytime with advantage, but it is unnecessary and extravagant to illuminate the space behind the glass. Lights placed directly behind stained glass appear at night like so many unsightly spots, so that in order to show the glass to advantage the light itself must be kept out of the line of vision. Fig. 20 illustrates a stained glass dome lighted in this way, and Fig. 19 shows the arrangement of lights above the dome.

It has been found that whereas 12 lights make a successful effect under a dome, it requires 48 lights above the glass before the design can be seen, and even then the effect is disappointing, except when the lighting in the lounge itself is reduced. The light from a flame arc lamp would in some cases form an ideal method of illuminating behind stained glass, and if a lamp were available capable of burning, say, 100 hours with one pair of carbons, one would be tempted to give it a trial. The work of trimming the lamp, and the cost of upkeep, however, might not be quite so ideal.

Smoking Rooms may be lighted in the same manner as lounges, except that they need not be so brilliantly illuminated. The wall framing and other woodwork is usually dark in smoking rooms, and this reduces the lighting effect to a considerable extent as a rule. It is better in these cases to instal the same number of lamps as in a lounge of equal size. Some fittings suitable for use in smoking rooms are shown in Fig. 21.

Direction Sign Lanterns are often used in passenger steamers, and are made in various forms to suit the surroundings. They are used to indicate the locality of bath rooms, lavatories, steward's and stewardesses' rooms, saloons, lounges, entrances, &c., and may be made as pendants, brackets or bulkhead fittings. The illustration Fig. 22 is a bracket with glass on both sides, suitable for fitting above a doorway. There are two supporting arms which, in addition to the lower flange, give ample support to the lantern. For exposed situations the glasses are double, a plate of opal glass with the lettering being inside and a clear sheet outside. Access to the interior of the lantern is obtained by a door at the bottom.

FIG. 21.—SMOKE ROOM FITTINGS.

Digitized by Google

Signal Lamps.—We now come to what is, perhaps, the most important lamp fitting on board a steamship—namely, lamps for navigating the ship. These are placed in strong copper or brass lanterns (Fig. 23) having dioptric lenses of a special form and size, which are fitted as follows :—

One lantern on the foremast showing a clear light.
,, ,, mainmast ,, a clear light.
,, ,, port lighting screen showing a red light.
,, ,, starboard lighting screen ,, a green light.
,, ,, stern of the vessel ,, a clear light.

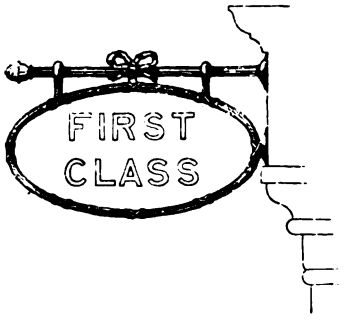

FIG. 22.—SIGN LANTERN.

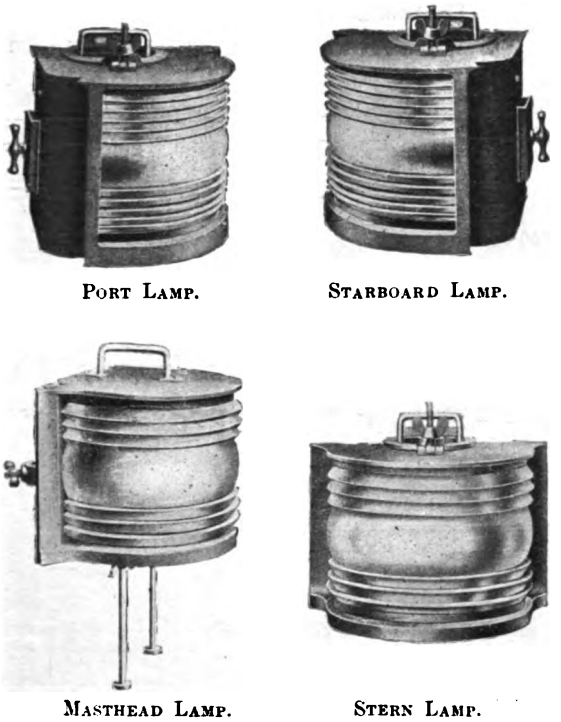
Dividing a circle into 32 sections or points, the position of the electric lamp filaments must be such that the following conditions are complied with :—

1. In the case of mast lamps, a uniform unbroken light must be visible in a forward direction from any position within 20 points of the circle—that is, 10 points on each side of the centre line.
2. In the case of side lights, the full light must be visible only on port or starboard sides within an arc of 10 points of the circle.
3. The stern light must give light only behind the vessel within an arc of 12 points.



PORT LAMP. STARBOARD LAMP.

MASTHEAD LAMP. STERN LAMP.

FIG. 23.

Fig. 24 is a diagram showing the arrangement of these lights. The full lines show the angles at which the full light begins to vanish, and the dotted lines the angle at which the light vanishes. Double filament lamps are used with filaments 1 in. wide. These are shown in plan by two parallel lines in the diagram, and are seen more clearly in detail in Fig. 26.

Navigation Lamps Indicator.—As safety in navigating a ship at night depends largely on the navigating lamps remaining always alight, it is an advantage to have some means of switching in a stand-by filament when a failure occurs, and at the same time give warning of the fault. An indicator which does more than this, made by Messrs. W. C. Martin & Co., is shown in Fig. 25. Each navigating lamp has two filaments, only one of which is in use at one time. The upper part of the indicator contains three fuses for each lamp (two line wires and one return wire). The lower part of the indicator contains a control panel for each navigating lamp. Each panel is provided with a signal lamp, magnet and barrel switch, and a main switch and test key is fitted below as shown. The handle of the barrel switch acts as a weight, and keeps the control rod down, except when prevented by the magnet armature.

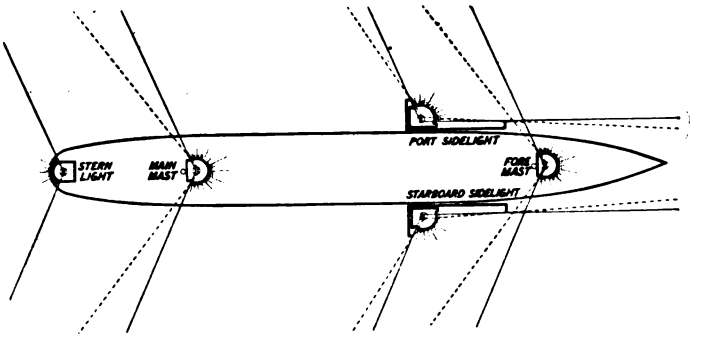


FIG. 24.—ARRANGEMENT OF NAVIGATION LAMPS.

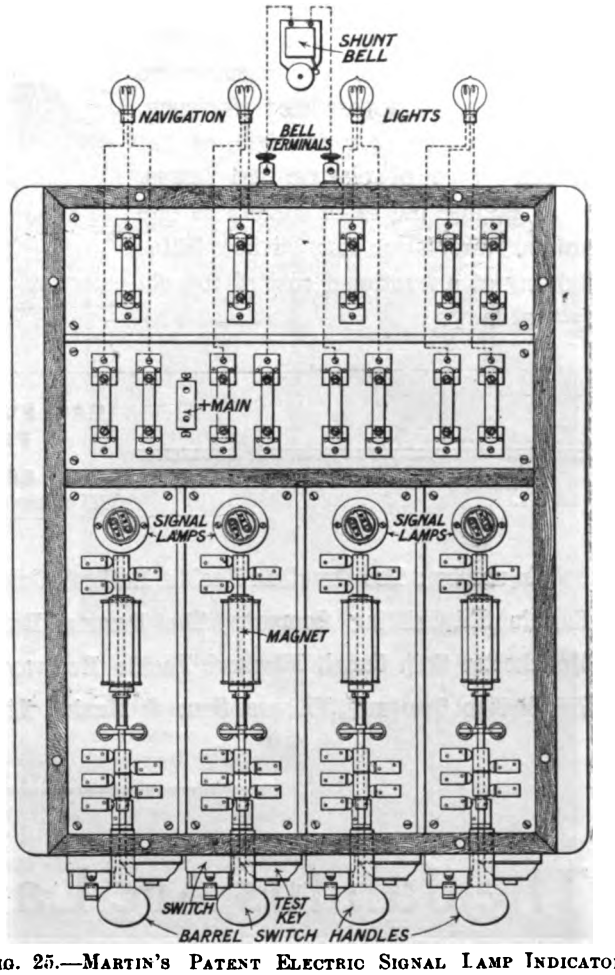

FIG. 25.—MARTIN'S PATENT ELECTRIC SIGNAL LAMP INDICATOR, RELAY AND ALARM.
Scale: One-sixth Full Size.

Normally the barrel switch is down, and in this position the magnet is in series with one of the filaments. Should this circuit fail, the magnet armature drops and puts in circuit the stand-by filament and also the signal lamp and alarm bell. The officer

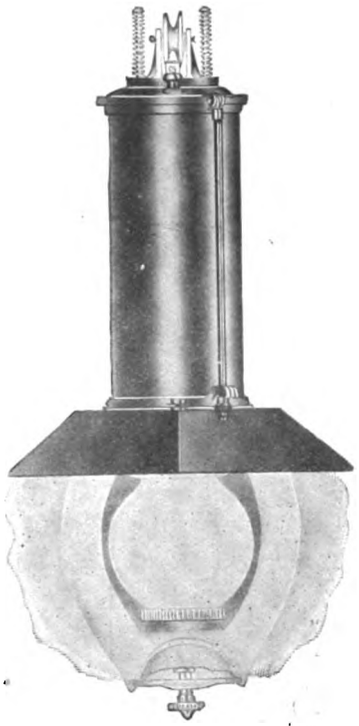
JANDUS

PATENT REGENERATIVE

ELECTRIC FLAME ARC LAMP.

The Jandus Regenerative Lamp is an English invention enabling flame carbons to be burned in an air-tight enclosure, the regenerative action enabling the chemicals to continually pass through the arc. This regenerative action gives an unparalleled efficiency. It will replace four to eight of the ordinary type of electric arc lamps, while taking the same current as one ordinary arc lamp, thus giving better lighting at a fractional cost of the old type of lamps



GAS, FUME AND WATER PROOF CASE.

4,000 Candle power.
Will efficiently light 50,000 to 100,000 super feet.

The Arc flame being contained within an air-tight enclosure, is totally unaffected by high winds or gales.

The lamp will burn 70 hours on one pair of carbons. It is the only flame lamp that can run continuously through long night shifts and foggy days without interruption to work for the purpose of trimming. There is an entire absence of shadows, and the light is thrown in a horizontal direction, rendering it an ideal lamp for the lighting of large spaces. It is the cheapest form of lighting extant.

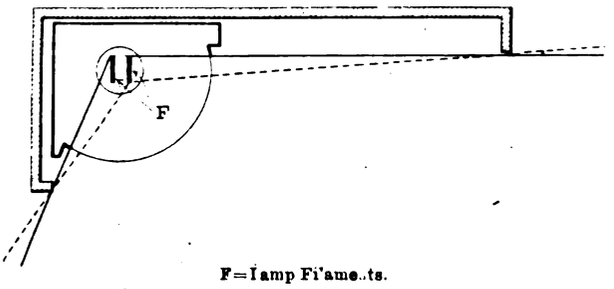
on duty now raises the barrel switch in order to stop the bell, but this action also inserts the magnet in series with the stand-by filament, and the armature, engaging with a collar on the switch rod, retains it in its upper position.



F=Lamp Filaments.

FIG. 26.—DETAIL OF NAVIGATING LAMP.

Should the stand-by filament circuit fail, the armature releases the rod, which falls, and the alarm is again sounded. The bell cannot now be stopped ringing till the fault is removed or the circuit switched off. The test key is used daily to ascertain if the apparatus is in good working order.

The Author desires to thank Messrs. Wm. McGeoch & Co., Ltd., for placing many illustrations at his disposal for use in this article.

Arc Lighting in Marine Work

For many years the lighting of dock and harbour sides was only carried out with a view to ensuring a reasonable amount of safety to passengers or workmen. Loading and unloading operations were rarely carried out at night time; the handling

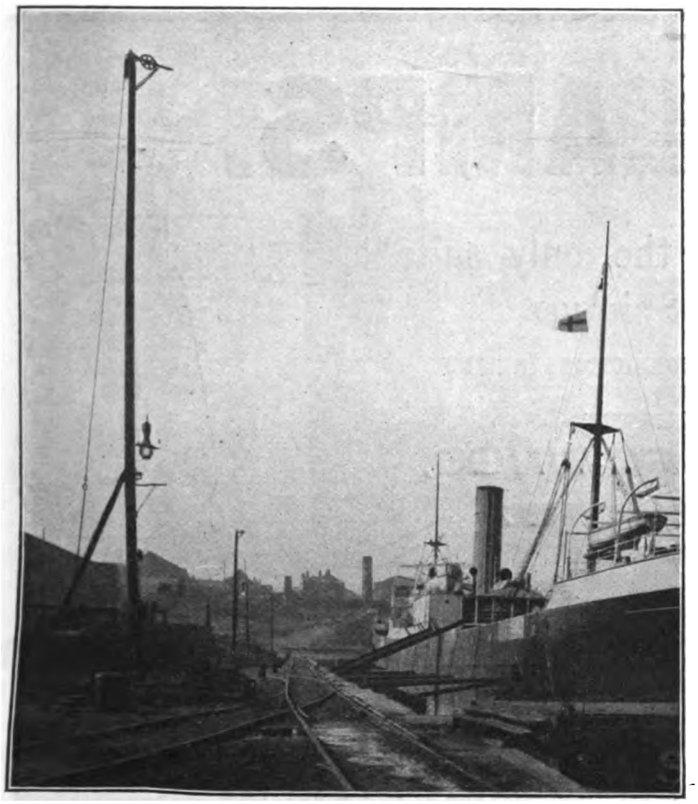


FIG. 1.—JANDUS REGENERATIVE FLAME LAMP AT WALLSEND-ON-TYNE.

of cargo which had to be effected after daylight was accomplished by temporary lights which were usually fixed over the spot where work was carried on.

The increased size and cost of present day ships have necessitated the brilliant lighting of docks and harbours. The interest and standing charges on a first-class ship now amount to hundreds of pounds every 24 hours, and it is therefore essential that all dockside operations should be carried on at the ship night and day, in order to save as much time as possible. The extra cost of brilliant lighting is so small an amount in comparison with the saving effected, that the great shipping centres have, almost without exception, considerably increased the illumination of their dock and harbour property.

Mists and sea fogs are always prevalent in seaport towns, and they materially affect the class of illuminant to be used on dock sides. It is necessary, in order to obtain the most satisfactory results, to use a light of an orange or yellow colour, as experience shows that this light penetrates any mist far more easily than white or violet coloured light. Incandescent gas is rarely used for this class of work, on account of the effect of severe wind and gales upon the mantles. The general unsuitability of high-pressure gas for dock work is also admitted, and, further, high-pressure pipes cannot be placed underground and subjected to the passage of heavy loads and railway trucks.

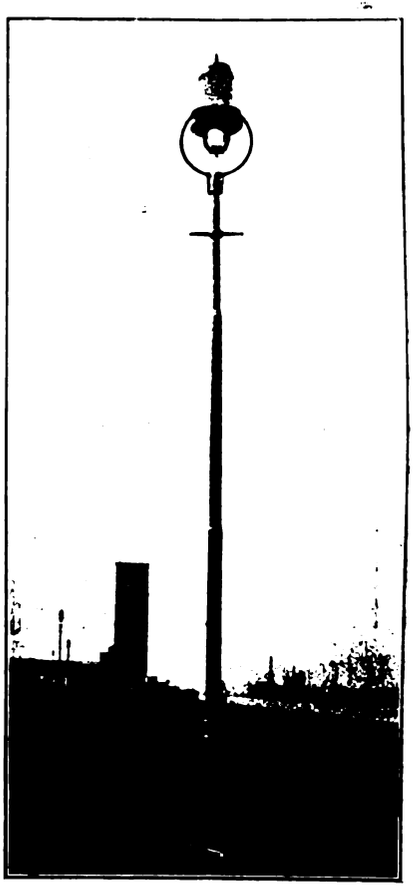

FIG. 2.—JANDUS REGENERATIVE LAMP AT TRAFFORD WHARF.

A lamp to give satisfaction in dock work should be of special design. The mechanism must be adequately protected from the severest gales and driving rain, and it must also be able to resist the action of salt water spray. It is essential that the arc should be totally enclosed or a gale may cause the complete extinction of the light. The Jandus Regenerative lamp has met with considerable success in marine work, a fact which may be attributed to its being the only enclosed flame lamp. It combines the advantages of the intense yellow light with a complete enclosure of the arc and mechanism. The lamp is in use in a large number of dock and harbour installations.

The Middle Docks & Engineering Co., South Shields, own three dry docks, which have the reputation of being amongst the busiest on the Tyne. In September last year their largest dock, 463 ft. by 63 ft., was opened, and at the same time the lighting of all three docks was considered. A number of exhaustive tests were carried out, and the Jandus Regenerative flame lamp was subsequently chosen. These lamps are burned

on a 550-volt direct-current circuit, and each lamp is hung at a height of 25ft. The very wide distribution of light from the vertical carbons is fully made use of, and some of the lamps are in a shed where they also serve the double purpose of throwing a good proportion of light on the adjacent dock.

It was recently reported by an official of the General Steam Navigation Co., in charge of one of their steamers using the above docks, that these were the best lighted docks he had visited in any country.

Swan, Hunter, Wigham & Richardson, Ltd., Wallsend-on-Tyne, have a dry dock of 550 ft. by 76 ft. where the regenerative lamps were installed 12 months ago. These lamps are placed 150 ft. apart, and hung from wooden poles 25 ft. high (Fig. 1). Work can be carried on in any part of the dock throughout the night. The lamps burn two in series on a direct current of 240 volts, one switch controlling each pair of lamps, thus allowing a small amount of light to be used when work is being carried on in one part of the grounds only.

Another excellent example of the efficient lighting of a large area is that of the Trafford wharf of the Manchester Ship Canal Co. (Fig. 2). With the complication of railway track and sidings, with standing trucks and timber stacks, &c., efficient and economical lighting would appear impossible. Lighting a total area of 1¼ million square feet there are 15 Regenerative lamps in three circuits of five lamps on 500 volts. The lamps are spaced at 200 ft. apart, and are 26 ft. to the centre of the lamps from the ground. At this altitude the clear way between adjacent tracks is well lighted.

On this ground shunting, &c., takes place all night, and from the Trafford wharf jetty boats are being unloaded continuously.

Brockie-Pell Arc Lamps for Marine Work.

In the accompanying illustration (Fig. 1) we show a lamp which has been designed by the Brockie-Pell Arc Lamp Co. for coaling work and ship lighting generally.

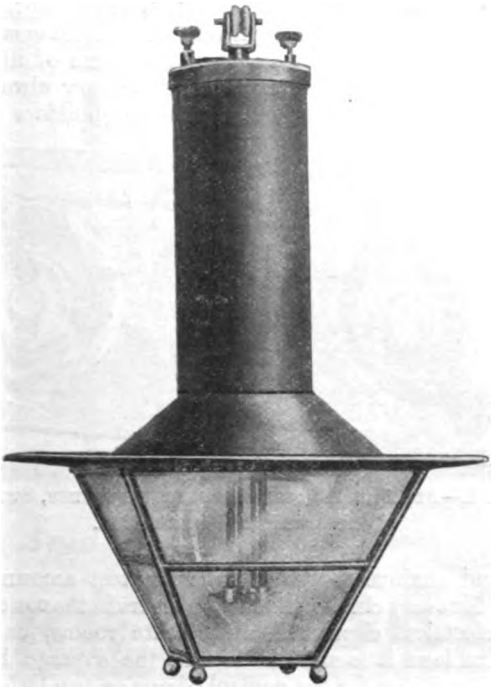

FIG. 1.—MARINE ARC LAMP.

One form of lamp of this description largely manufactured by this firm is their open type "Admiralty" pattern lamp fitted with square lantern with two doors adjacent to each other. This lamp burns about 10 hours, and runs on 50-volt circuit or in series on higher voltage. The lamp, a general illustration of which is shown (Fig. 2), is insulated on both poles throughout, and is fitted with special terminals. For Government work it is fitted with malleable castings.

The lamp is the firm's well-known differential type, controlled by a chain brake, but is fitted with special terminals, the sockets in which are of different sizes to take corresponding connections on the positive and negative leads from the ship's mains; this provision being made to prevent the reversing of the lamp by inserting the leads in the holders incorrectly. The case is supported from a ring at the bottom by means of a thumb clip and wing nut so as to be readily lowered for special attention. Special holders are provided, the lower being capable of alignment in a horizontal and vertical direction. The lantern is fitted with substantial balls at the bottom of the frame for the purpose of standing the lamp on the deck without breaking the lower pane of glass. From the illustration and the above description it will be seen that the whole terminal arrangement at the top of the lamp is entirely waterproof, and that all provisions have been made for contingencies in handling

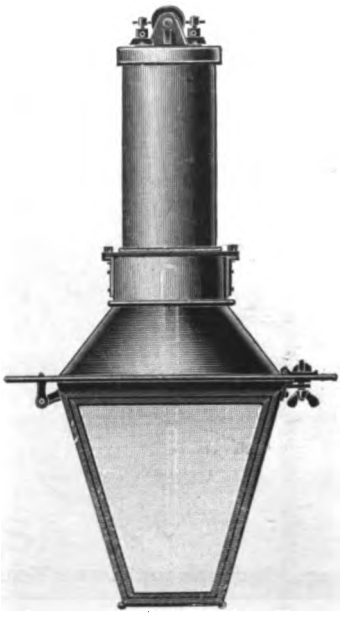

FIG. 2.—OPEN TYPE ARC LAMP FOR MARINE WORK.

the lamps. The controlling gear is fitted with the well-known Brockie-Pell subsidiary brake giving a steady feed to the carbons. The lamp is generally supplied with a separate resistance, but overhead resistances, rigidly attached to the lamps, can be had when required.

A special enclosed type arc lamp made also for ship installations by the Brockie-Pell Arc Lamp Co., is shown in Fig. 1. This lamp is insulated on both poles, and has special terminals at the top of the lamp. The case and lantern dome, with the reflector, are all made in one piece, the lantern bucket being fitted with small panes ribbed horizontally and vertically.

The bucket is arranged to swing downwards, on a hinge in one side of the lantern, and, when in this position, hangs quite clear of the globe. It is provided with large balls at each corner of the bottom lantern pane, to prevent the latter being broken when stood on the deck.

The inner portion of the lantern case forms a complete enclosing case for the lamp itself, excluding all wind and protecting the globe and other portions of the lamp from atmospheric conditions. The globe itself is suspended by a gun-metal ring sprung tightly to the globe cap. The illustration (Fig. 2) shows a twin carbon lamp arranged in this manner. The lamps are supplied with resistance, separate or overhead as desired, to run singly on 100 or 200 volts, and are specially designed so as to be transported in one unit to any position. In order to prevent the reversal of the lamp through changing

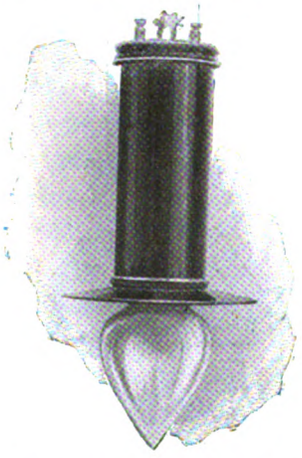
Digitized by Google

over, the positive and negative terminals are of different sizes, similar thimbles being fitted to the arc lighting circuit leads.

This firm also make ship and bulkhead lighting fittings which are largely sold by them in connection with their "B.P." metal filament incandescent lamps. The metal filament lamps are made throughout at Wimbledon and, we understand, are very satisfactory. The firm are also specialising in power transformers which are an outcome of their auto-transformer business in connection with house supplies.

Foster Lamps for Marine Work.

A type of arc lamp which has been specially designed for marine work is that shown in the accompanying illustration. It is made by the Foster Arc Lamp & Engineering Co., of Wimbledon. The construction is very solid, and special attention has been given to the water-proofing of all parts.



FOSTER ARC LAMP FOR MARINE WORK.

The lamp is of the coil type, is of the simplest form, and is so arranged that satisfactory operation under the somewhat severe conditions of marine service is well assured. The globe is supported by a wire strap which passes under the globe, the two ends projecting through the top plate being tightened by screws—a simple device, but one well calculated to withstand the jolting and swaying met with on board a boat. This is not shown in the illustration. The lamp gives about 1,000 c.p., burning 60 hours per trim, and taking 400 watts per hour. Although direct-current lamps are usually required for marine work, the firm upply an excellent model for alternating-current service. A goodly number of Foster enclosed marine lamps are doing yeoman service both on board ship and in various docks and harbours.

Kaye's Copper Oil Cans for Marine Work.—A not unimportant part of any engineering equipment is the oil can. And to preserve the amenities, to permit the plant to run smoothly, and to keep the engine room clean it is necessary that this should be of sturdy construction and capable of delivering a supply of oil wherever it is needed. These criteria are fulfilled, it is claimed, by the copper and brass oil cans made by Messrs. Joseph Kaye & Sons, of Leeds. These cans are practically seamless, and may be fitted with a double wrapped spout, which may be bent into any position without break or leakage. The cans are made in eight sizes, varying in capacity from $\frac{1}{6}$ to 2 pints.

Accessories for Cabin Lighting, Heating and Bells.

The extension of electric lighting on board the modern passenger vessel has naturally brought with it improvements in methods of controlling cabin lights and in the provision of special facilities for the use of extension lamps, radiators, telephones and bells. Many of these improvements, which were looked upon as refinements a few years ago, have now come to be regarded as absolute necessities, particularly on board an Atlantic liner. The introduction of accessories for work of this class has entailed considerable labour on the part of manufacturers, and every credit is due to them

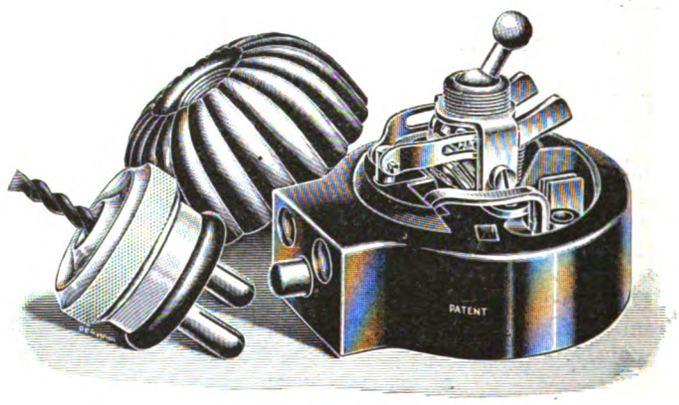


FIG. 1.—AUTO-COMBINATION SWITCH AND WALL PLUG.

for the standardisation of many of the articles now in common use. Messrs. A. P. Lundberg & Sons have been prominently identified with this class of work, and, in fact, they might almost be termed the pioneers of the electrical accessory business. The range of their products includes almost every type of combination for the control of lighting, heating and bell circuits for ship work.

Users of electricity on land are always being impressed with the convenience of electric light and the advantages which it possesses in this respect over any other form of illuminant. On board ship, where electrical energy is now always available, it is not surprising to find that shipbuilders are both

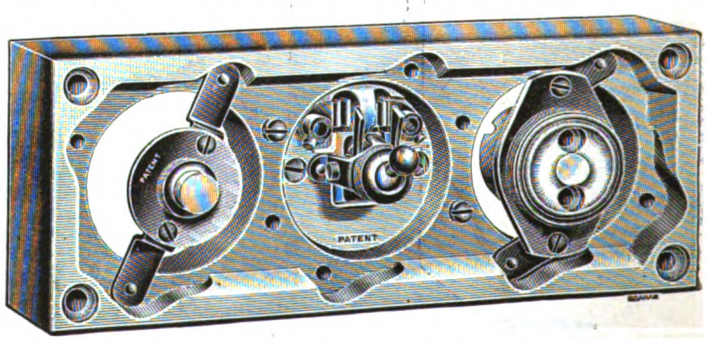

FIG. 2.—ADAPTABLE COMBINATION, SHOWING PUSH, SWITCH AND SOCKET IN RECEPTACLES.

willing and anxious to provide the greatest amount of convenience for every class of their passengers in the control of the various electrical circuits in their state rooms, cabins, &c. Whereas on land it is unusual to find the average household fitted with switches for the control of one or two lights from a number of positions, it is practically a necessity that a ship's passenger should be able to light up his cabin or ring for an attendant from, at any rate, two positions.

The specialities of Messrs. Lundberg have been developed with a view to provide the maximum of convenience in control with a minimum of wiring trouble. The space at our disposal

INSULATING MATERIALS.

P. & B. Materials have a well-merited, world-wide reputation for insulative efficiency, and the universal satisfaction which they afford is fully demonstrated by the fact that the most important Electrical Systems throughout the world constantly employ them.

It is poor economy to experiment with untried and untested insulating materials which may be offered at low prices when those with an established reputation for efficiency can be obtained at a reasonable cost.

is too limited in which to introduce the large number of combinations which can be obtained, but it will be interesting to comment on a few principal lines.

Fig. 1 illustrates what is known as the Auto-combination switch and wall plug, which is becoming the standard device for the control of radiator circuits. It will be noticed from the illustration that an ordinary two-pin plug is used, but when this is inserted in the socket the plunger is depressed, which admits of the tumbler switch being used in the ordinary manner, but removal of the plug causes the circuit to be broken at the switch itself and not at the contact prongs.

In Fig. 2 is illustrated an adaptable combination which comprises a standard porcelain base. Into this base can be fitted any desired type of accessory, such as bell push, tumbler switch and wall socket, as shown in the illustration. Two switches and one socket can be used, two sockets and one switch, or one switch and two bell pushes, just as may be necessary without alteration to the base. This base is suitable for both surface and flush fixing in either a vertical or horizontal position. The same base may be used for three-pin connections, and bell pushes and additional contacts can be provided for bell and telephone extensions without necessarily using any of the three recesses. The switches which may be fitted can be of any standard "Lektrik" type, not necessarily the ordinary single or two-way type.

A word may be said at this point regarding the details of construction of Lundberg switches. Needless to say accessories for the control of lighting and heating circuits on board ship require to be substantially made and efficiently insulated. Up to the present time mica has proved to be the best insulating material for switch work, and in all Lundberg switches this form of insulation is employed in connection with the current-carrying parts. It is preferable in ship work that the interior metal parts should be tinned as a preventative against the action of sea air. A feature of the Lundberg construction in switches is the provision made in the action of the switch for effectively locking the arm in the "on" position. There is usually a considerable amount of vibration on board ship, and with poorly designed accessories, a switch may be jarred from the "on" position and the circuit broken in consequence. Another feature is the provision made in Lundberg accessories for a locked cover, either to switches or wall sockets as the case may be.

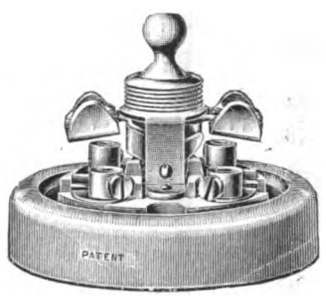

FIG. 3.—TWO-WAY AND OFF SWITCH.

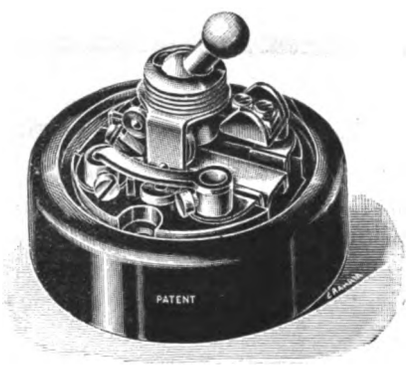

FIG. 5.—ALL OR PART AND OFF SWITCH.

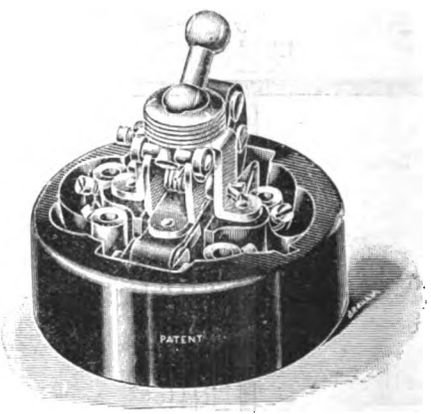

FIG. 6.—GENERAL VIEW OF "MARVEL" SWITCH.

As to methods of light control in cabins, the simple two-way switch with intermediate switch which gives control of one or more lights from any number of positions is too well known to need special reference. The value of the intermediate two-way switch is frequently overlooked, as in cabin lighting it is exceptionally useful. A cabin having a number of berths will be lighted by only one lamp, but each sleeper should have control of the lamp. This facility is readily afforded by the use of the intermediate two-way switch. By the use of a two-way and "off" switch, such as is shown in Fig. 3, two different lights can be controlled from one point. A modification of this switch is suitable for series-parallel lighting with two lamps, the effect produced being a dim light with the lamps in series and the full light with the lamps in parallel. This full and glow effect can also be obtained with a two filament incandescent lamp controlled by a two-way and off switch. Previously this pattern of lamp has been fitted with filaments of different candle-power—one, say, 16 c.p. and the other 2½ c.p. The filament of the latter is, however, most fragile, and will not withstand for long the shocks due to heavy seas and vibration on shipboard. This can be readily understood, seeing that it is the custom to place the lamp in a rigid fitting fixed either to the cabin roof or ship's side. To obviate this difficulty two filaments of equal size are used in the lamp, and are placed in series for dull light or glow, and for full one filament is cut out altogether. Fig. 4 is a diagram showing how a lamp of this pattern can be controlled from two positions, being turned to glow, full or off. This combination utilizes the "Marvel" switch, which is referred to below.

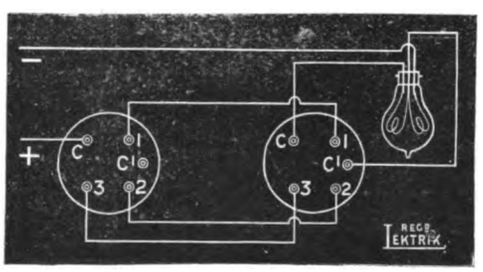

FIG. 4.—DIAGRAM SHOWING TWO FILAMENT LAMPS CONTROLLED FROM TWO POSITIONS WITH "MARVEL" SWITCH.

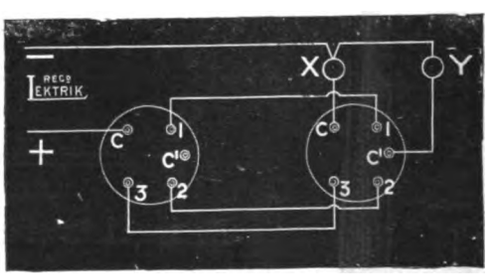

FIG. 7.—CONNECTION DIAGRAM SHOWING CONTROL OF TWO LAMPS, X ALONE, Y ALONE, AND OFF, FROM TWO POSITIONS WITH "MARVEL" SWITCH.

Fig. 5 illustrates another pattern of cabin switch by the use of which all or part of the lights can be turned on or off. The Lundberg "Twinob" switch is now well known and needs no description. It is practically a combination of two tumbler switches under one cover, the two operating knobs being slightly smaller than that usually provided. The switches are quite independent of each other, and either one, or both together, may be used. For instance, in a cabin, one knob might control the light and the other a small ventilating fan. This pattern of switch can be used for both flush and surface work.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

Possibly the greatest variety of combinations in circuit control is afforded by the use of the Lundberg "Marvel" switch, which gives facilities for switching on or off a number of lights from two positions. This switch has the advantage of allowing control of the circuit at all times irrespective of the position of the switch knob. Fig. 6 gives a general view of this switch which has three positions, each of them well defined. The point to emphasise is that it greatly simplifies the wiring connections, and only requires the use of one pole in the switch itself. Fig. 7 is a typical diagram showing the use of the Marvel switch for the control of two lamps from two positions.

Ships' Illumination and Osram Lamps.

The carbon lamp is gradually giving place to the metal lamp for illumination purposes in connection with every class of marine work. Experience with the metal lamp on land has been productive of very valuable results as to its ability to withstand excessive vibration, wide variations of voltage and

FIG. 1.—CEILING FITTING FOR MARINE WORK.

FIG. 2.

application to practically every known pattern of fitting. The modern warship and passenger boat are such stable vessels that it is not uncommon for ornamental pendant fittings to be used in saloons and cabins, special provision being made for securing the fittings in very rough weather. At the same time the majority of ships' fittings are of the rigid type and with this pattern the lamp is subjected to the harshest possible treatment so far as vibration is concerned.

The Osram lamp has met with great success in illumination on terra firma, and it is perhaps difficult to conceive of any general or specific purpose to which it has not been applied. Similarly on shipboard and for cargo lights it is being installed

FIG. 3.

on an extensive scale. The mechanical strength of the filament and its high economy of energy combined with intensity of illumination make it especially suitable for shipwork, and it is not surprising to find that Osram lamps are becoming more and more employed in this sphere.

The fittings used on board ship are, in the case of saloons and first and second class cabins, of a necessarily ornamental nature, and the Osram lamp lends itself peculiarly adaptable to bracket, ceiling fitting, pendant or table light.

That these remarks are true will be gathered by an examination of the accompanying illustrations, which show fittings designed by the General Electric Co. for use on board ship in connection with Osram lamps. Fig. 1 shows a ceiling fitting appropriately known as the "Lusitania." The fitting itself can be supplied in polished brass, oxidised copper and oxidised silver, while the bowl can be either of clear, frosted or cut glass. This fitting is designed to take one Osram lamp, and should find a wide application in saloons and other parts of the living room accommodation on board the modern ship.

Fig. 2 shows another type of ceiling fitting supplied for marine work, though of a cheaper type, and, therefore, more suitable for the less ornate parts of the ship. It is simply made in polished brass, and since simplicity is true beauty, its good points speak for themselves in the illustration.

Fig. 3 shows a two-light bracket which has been designed for marine work. In manufacturing these fittings it must be remembered that space is a, if not the, deciding factor on board ship. Brackets with long projecting arms are quite out of place. In fact, they would very soon be knocked out of place in a literal sense if provided with any part which sticks out much from the bulkhead. The bracket shown is, however,

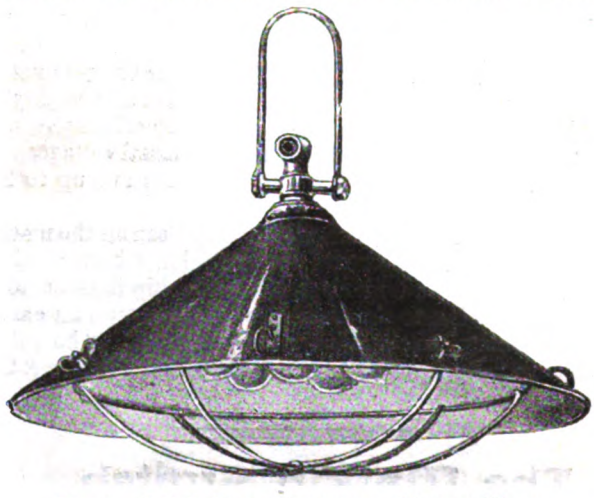

FIG. 4.—G.E.C. CARGO FITTING FOR MARINE WORK.

neat and compact, and should not run into danger from this cause, being only 4¼ in. in projection.

Turning to a part of the ship which the ordinary passenger is not generally allowed to visit, it must be mentioned that good light is just as much, perhaps even more, required in the stokeholds and engine rooms than in the cabins. The fittings must be well and strongly built, must be out of the way as much as possible, and yet must be capable of throwing the light down where it is required. Such lights are required constantly in the working parts of ships. On the other hand, there are other parts, in the holds, for instance, which it would not be necessary to light continuously, and where it might not be expedient

FIG. 5.

FIG. 6.

or possible to use permanent lighting. A hold filled with cargo has no room for ordinary fittings, and it is further necessary when loading that a good light should be thrown down the hatchway. Fig. 4 shows a fitting which has been designed by the General Electric Co. for this purpose. It consists of a holder, bearing from three to eight lights, which is contained in an enamelled iron reflector. This reflector is fitted with a wire guard to prevent damage to the lamps. Arrangements are made so that the fitting can be suspended wherever required over the hatchway. Figs. 5 and 6 show other fittings

Digitized by Google

which have been designed by the General Electric Co. for marine work.

As regards the actual application of Osram lamps to ship work it will not be without interest to mention that these lamps are to be found on a number of British warships, as well as on the ships of the Brazilian and Argentine navy. The metal filament lamp was once supposed to be a fragile article, but there is no doubt if it can stand gun fire it can stand anything.

The suitability of these lamps for marine work is, in fact, shown by the statement that one of the White Star Line ships which was recently fitted throughout with Osram lamps has recently returned from a five months' cruise, and only one lamp failed during the whole of this time. The boat is leaving for another cruise with the same lamps, but is taking only half the usual number of spare lamps with it.

"Rugby" Metal Filament Lamps.

Among the firms who are doing their share in furthering the use of electricity on board ship are the Rugby Lamp Co., a firm which has a modern factory at Rugby for the production of incandescent lamps. They, in fact, make a speciality of metal filament and carbon filament lamps for all purposes.

The "Rugby" lamps are made in all the usual voltages, and in candle-powers up to 80 in the low-pressure and up to 200 in the high-pressure types.

Although the "Rugby" lamps have only been on the market for about two years, important contracts have been obtained from leading railways, tramways and steamship lines at home and abroad. Owing to the success of these lamps an extension of the factory has already become necessary. The selling agents for the "Rugby" lamps are Messrs. J. L. Cateaux & Co., of London.

The Watkin Switch.

Numerous attempts are made to provide the ship's passengers, particularly the first-class, with some means of dimming the electric lamps in their cabins. The full light is always too bright to sleep under, and yet it may be necessary in the case of invalids or "poor sailors" to keep a glow on the whole time. The two-filament lamp and series-parallel control of two separate lamps only give two definite illuminations. A perfectly regulated light can only be obtained by means of a reducing resistance, by the use of which considerable economy is effected in the current consumed.

The Watkin switch was introduced a few years ago to provide a means of "turning down," to borrow a gas phrase, electric light. Judging by the large number sold, and the appreciative comments of users, the claims of the makers appear to be fully justified. The device is compact in size, and easy to operate. It comprises a number of neat carbon resistance frames, and a special pattern of tumbler switch. Movement of the latter causes the switch arm, which is, of course, longer than the ordinary switch, to travel over a radial group of contacts. These contacts are connected to the various resistance frames, more or less of which are brought into circuit by the movement of the switch. It is claimed that the saving effected is from 12½ to 80 per cent. by the use of the switch. The same device is employed for the reduction of the speed of small electric fans.

The Watkin switch is made by the Adams-Watkin Co. in five sizes to absorb energy as follows:—70, 130, 70 to 200, 200 to 440, 450 to 600 watts.

The switch is specially suitable for use on board ship, for it can be made with any number of variations of resistance, although the standard pattern has seven—and the passenger can regulate the light or fan as desired. On board the ss. "Minnewaska," which is fitted throughout with the Watkin switch, it is made without an "off" position, and consequently has an independent switch to cut off current when necessary.

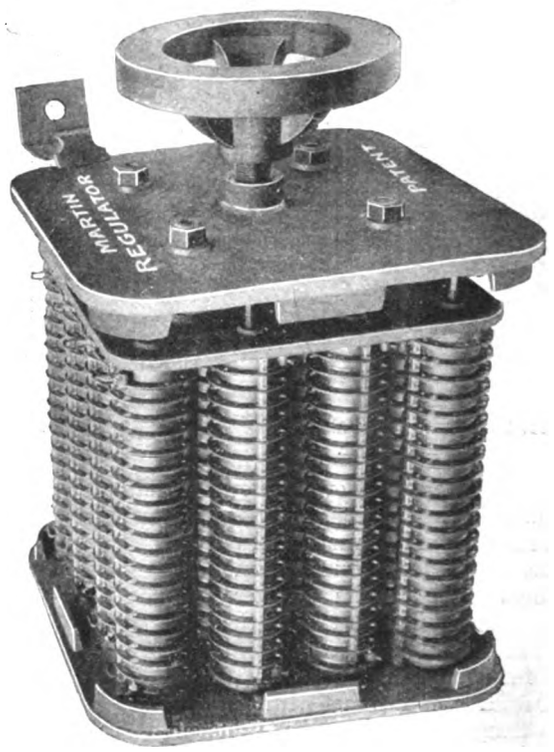
Martin's Regulator Switch.

A useful regulator switch, which should find a ready application on shipboard for the control of fans and other similar apparatus, is manufactured by the Electrical Regulators & Economisers, of Liverpool. The general arrangement of the regulator, which consists of a number of cells containing an elastic mixture and built up into a unit, is shown in the accompanying illustration of 16 piles or ways of 20 cells.

The mixture, which is indestructible in the ordinary sense of the word, is contained in small round brass cells lined with special bisque porcelain that is not affected by heat. Each cell is provided with a convector flange and piston, so that a number may be built up either in series or parallel-series to the capacity desired, whilst the cellular form allows an exceedingly good heat conduction from the centre of the mixture. This gives, it is claimed, reliable and steady working for lengthy periods as a resistance or convector.

Upon varying the pressure on the pile of cells by means of a hand-wheel, a quite unusual and gradual range of resistance is possible. No liquids or moving contacts are used, while the mixture is not affected by heat below very high temperatures.

Some idea of the flexibility of resistance range and carrying



MARTIN REGULATOR (CAST-IRON COVER REMOVED).

capacity may be gathered from the following figures: Each unit cell has a minimum resistance of 0·2 ohm, whilst the maximum may be over 200 ohms, and an even longer range is attained by varying the mixture from the standard which has been adopted for general purposes. The carrying capacity is 10 amperes per cell, but this may be increased if heavy terminals are substituted for those of the standard type. Continuous dissipation of heat may be at the rate of 20 watts per cell at ordinary atmospheric temperatures.

These appliances, which are primarily intended for commercial uses, may at nominal extra expense be fitted with separate and collective adjustments and connections, and so arranged they would form a most useful addition to the laboratory for very many and varied purposes, so great being the range that the same appliance may be used as a resistance on all voltages from 2 or 4 volts up to the higher pressures. These regulators have already been supplied to Government departments, many leading laboratories and scientists, and to over 60 Corporation supply departments, amongst other purposes being the testing of meters to comply with the new Board of Trade meter regulations and shunt field regulation.

The regulator has been patented in all foreign countries.

"Tantalum" Lamps and Fittings for Ship Lighting.

It is scarcely surprising to find that metal filament lamps are now receiving a wide application for ship illumination, as high efficiency leads to great economy in energy consumption. The outstanding objection, in fact, to the introduction of this particular class of lamp was the high initial cost, but with increased facilities of manufacture, important developments have taken place, and the prices of these lamps are being considerably reduced. In this respect the makers claim there has been no lamp in which the development has been so marked as in the case of the "Tantalum." Placed on the market some years ago, they proved themselves to be the only really commercial lamp at that time, whilst the extraordinary tests to which they have been put have only demonstrated their superior strength. They are, Messrs. Siemens inform us, specially suitable for ship and train lighting where considerable vibration is experienced, and very effective lighting installations can be made when "Tantalum" lamps are employed in suitable types of fitting. Many installations of this class have been carried out by Messrs. Siemens Bros., the manufacturers of the "Tantalum" lamp, and we are illustrating here a few of the types of fittings which have been most widely adopted by them for this class of work. The majolica fittings are of a very cheap and efficient design, whilst they are also easy to instal and very artistic in appearance. We illustrate herewith (Figs. 4 and 5) two designs of this type of fitting which can be obtained in 16 or 18 different styles. They are not affected,

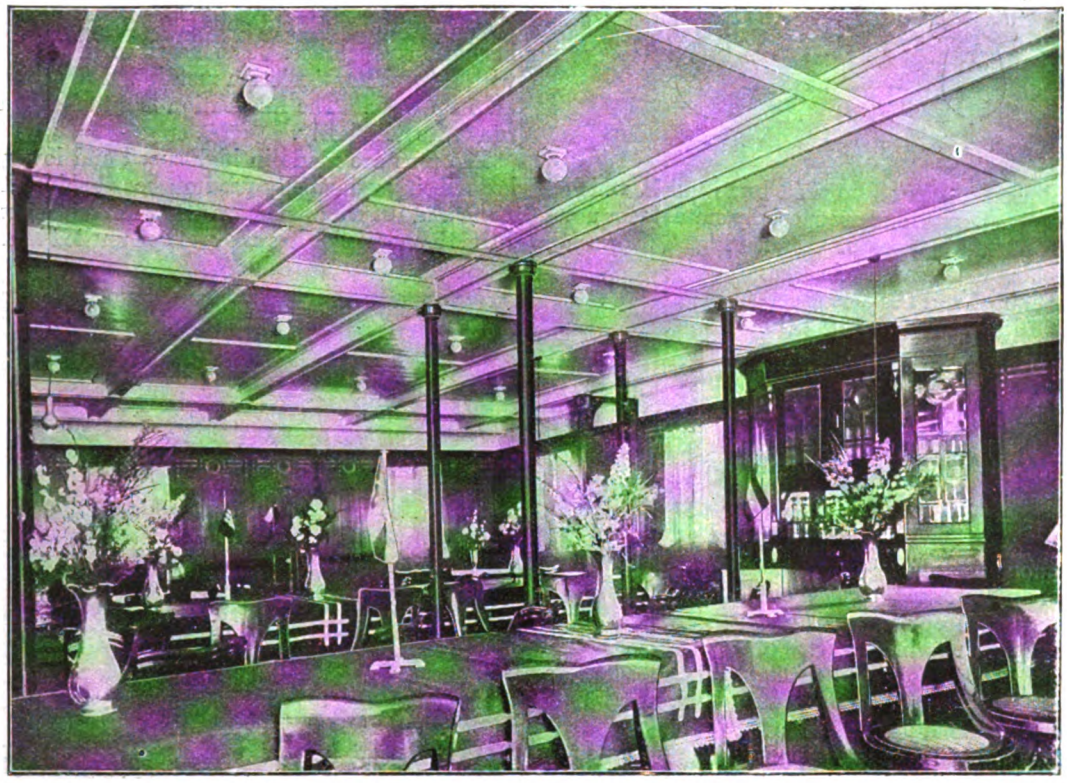

FIG. 1.—SHIP'S CABIN EQUIPPED WITH MAJOLICA FITTINGS.

it is said, by atmospheric conditions, and, with the exception of the lamp holder, are composed entirely of insulating material. Fig. 1 shows a ship's installation in which majolica fittings are installed. We also illustrate herewith (Fig. 6) an example of the artistic brackets of fixed design, which can be supplied in

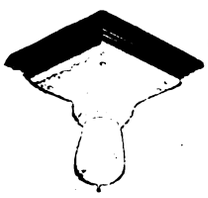

FIG. 4.

FIG. 5.

FIG. 6.

polished brass, oxidised copper or bronzed brass finish, which are of rigid and massive design, and are specially suitable for use in the saloons of the larger types of vessel. Fig. 7 shows a special design of ceiling fitting for use in cases where the space is limited and the roof necessarily rather low. In this type of fitting the Holophane type of glassware is used to concentrate the light in a downward direction, thereby obtaining the most efficient illumination possible. Messrs. Siemens Bros. also stock a comprehensive number of designs of watertight and weatherproof fittings specially suitable for use in exposed positions on board ship. One of these is illustrated in Fig. 8, but should any special design of fitting be required they will be prepared to get out designs to suit any special requirements, and to submit the same, with estimates, free of charge. A special type of cargo fitting (Fig. 9) is illustrated here. This fitting can be supplied for any number of lamps between two and ten for 25 c.p. or 50 c.p. lamps; it is arranged with a jockey pulley directly over the centre, with two rope grips at the base, which enables it to be fixed at any required angle.

It is also specially protected so that the lamps cannot possibly be broken with any ordinary usage. These fittings seem worth the consideration of all who are concerned in ship's installations, and Messrs. Siemens Bros. inform us that they will be pleased to supply any further particulars regarding them which may be required. We publish two illustrations Figs. 2 and 3, of a small pleasure yacht, the one showing the exterior, from which the size of the boat can be seen, and the other the interior of the cabin, in which the special types of ceiling fittings may be noticed. Messrs. Siemens Bros. have carried out installations on vessels from the smallest to the largest, some of these only requiring a few lamps and others in which over 1,000 lamps are installed.

FIG. 7.

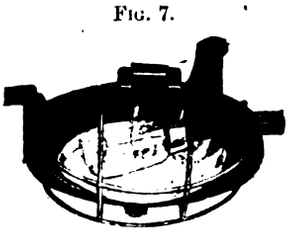

FIG. 8.

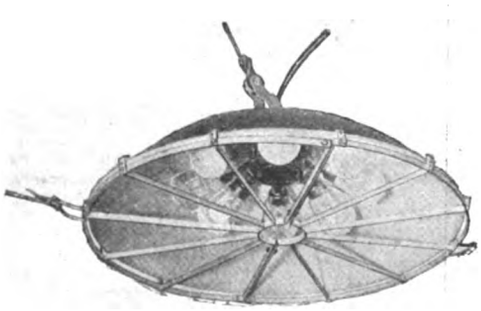

FIG. 9.

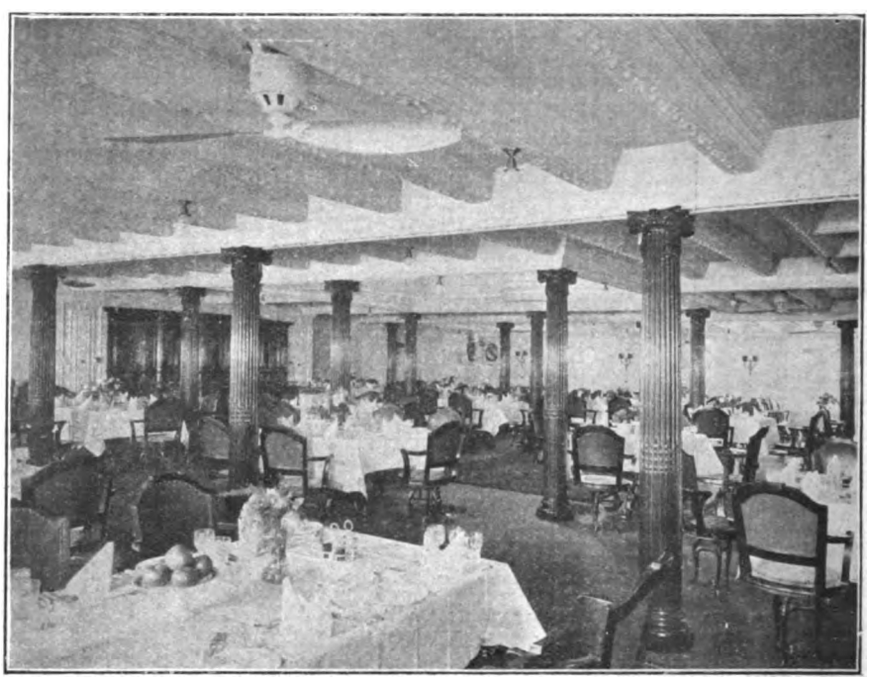
E.M.I. Ship Fans.

Messrs. Hogan & Wardrop's E.M.I. fans have created a sterling reputation among all classes of fan users, and the wide variety of fans and small motors they supply, covering in all 109 types, are suitable for every purpose for which fans are utilised in tropical countries, home, marine and for workshop use. All these fans are well made and of the best materials. Only double cotton and double silk covered wires are used for the armature and field coils. These conductors have a high insulation resistance. The bearings of these fans are fitted with a special anti-friction metal, and they can be adjusted to take up wear. The lubrication is automatic, and the motors run quite noiselessly.

The fans are made in high-speed and low-speed types, the latter being principally used on board ship. Porthole fans of 12 in. and 16 in. diameter are fitted with six brass blades, and the 20 in. diameter size has six black enamelled iron blades. These



VIEW IN SALOON OF SS. "ORVIETO," SHOWING INSTALLATION OF E.M.I. CEILING FANS.
By permission of the Orient Steamship Co.

blades are specially bent to displace a large volume of air. Cabin fans of 9½ in., 12 in. and 16 in. diameter and provided with six brass blades, and ceiling fans are made in four sizes: with two blades, having a sweep of 28 in., 40 in. and 60 in., and with four blades, having a sweep of 60 in.

The parts of these fans are made to gauge, consequently they are interchangeable, and spare parts can be easily supplied. The standard finish is black enamel with gold lines and polished and lacquered bright parts.

During the last 12 months this firm has equipped 26 liners with fans, and the photograph reproduced herewith shows their fans in position in the saloon of the Orient Co.'s steamer "Orvieto." We are indebted to the managers of the Orient line for permission to reproduce this illustration.

Messrs. Hogan & Wardrop's fans are in use in various parts of India and Canada, Zanzibar, Sierra Leone, Suez, Hong Kong, Singapore, Shanghai, &c. In some of these places the climatic conditions are in themselves a severe test of the successful running of any fan. It might also be pointed out that without these fans the climatic conditions in the places mentioned above would severely test both the temper and constitution of the European inhabitants. The electrically-worked fan prevents the too great ascendancy of this deplorable state of things.

"Arctic" Propeller Fans.

Every modern vessel is fitted with electric fans of one type or another in order to ensure proper ventilation of the different parts of the ship. A fan which has met with every success of recent years is that known as the propeller fan, this being distinguished from the box blade fan by the broad open ends of the blades. The Wilson-Wolf Engineering Co. specialise in electric fans and have a large number of their "Arctic" fans in operation.

The "Arctic" propeller fans are fitted with combined thrust and journal ball bearings, so that they are suitable for working either vertically or horizontally. The makers claim that large volumes of air can be moved with these fans for a low energy consumption and that they are extremely quiet in working. The fans are made in standard types and the construction includes an iron ring with four wide seatings for fixing to the wall, and to this ring the motor is bolted by separate arms, thereby giving rigidity and strength. The fan blades are securely bolted to the motor spindle and two bearings only are employed.

The motors are series wound, totally enclosed in the 12 in. and 15 in. sizes and enclosed ventilated in the 18 in. size and upwards. The commutator and brushes are accessible through removable covers. Where the fans are required to work in exposed situations in which they are subject to the action of steam or acid fumes, the motors are totally enclosed.

Marelli Fans for Marine Work.

The accompanying illustrations show the contributions which Messrs. Ercole Marelli & Co. have made towards the proper ventilation of ships' cabins and other passengers' quarters. This firm have had a wide experience of this class of work and, in fact, supply fans of all descriptions, including special cabin fans, low ceiling fans for use in ships' saloons, as well as desk, exhaust and wall fans.

The fan illustrated has been designed in response to a wide demand for a new type of oscillating fan. This fan can

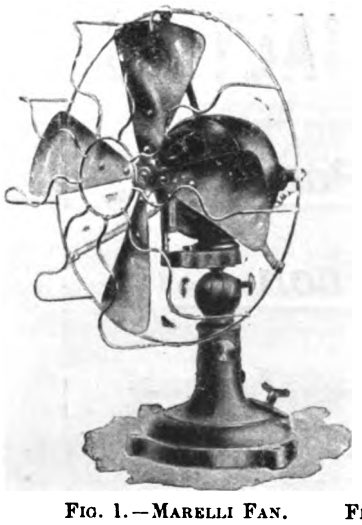

FIG. 1.—MARELLI FAN.

FIG. 2.—MARELLI OSCILLATING FAN.

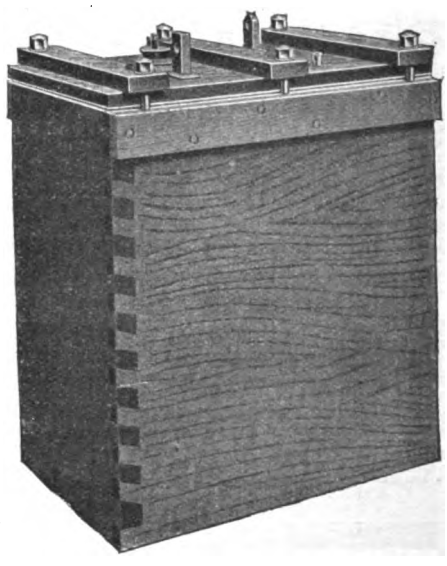
be arranged to distribute the air either horizontally alone or in all directions. In the latter case the fan body oscillates as shown in Fig. 2. This set, we are informed, runs both smoothly and silently and is, therefore, specially adapted for "living room" work. The motor used in connection with these fans can be supplied for all voltages and frequencies.

Messrs. Ercole Marelli also supply electrically-driven centrifugal blowers and pumps as well as small electric motors of both the continuous and alternating-current type.

Yacht Lighting.

The practice of installing a battery of accumulators in connection with the electric lighting of a yacht is so universal that there is no need to emphasise the advantages which such a practice offers. The Chloride Electrical Storage Co., of Pendlebury, Manchester, have for many years past made a speciality of this work, and have supplied the "Chloride" accumulator to many of the principal yachts both at home and abroad. The company's well-known special Planté type of positive is employed, the construction allowing the electrolyte to circulate right through the plate from one side to the other, thus ensuring even working and taking the fullest advantage of the entire surface of the active material.

Special "box" type negative plates are used in conjunction with the company's wood separators, these latter being the exact size of the plate, grooved on both sides, and specially prepared and treated by a patent process. The separators are highly porous, thus permitting a free circulation of the acid, while all possibility of internal short circuits is absolutely precluded, a point which, as engineers will at once appreciate, makes the separator of special value for yacht cells. The boxes are constructed of well-seasoned teak, dovetailed together,



"CHLORIDE" ACCUMULATOR FOR MARINE WORK.

and are impregnated with wax, or thoroughly well coated with acid proof paint as desired.

Ample freeboard is allowed between the top of the plates and the lid, and any possibility of the acid slopping over is prevented by rubber joint rings. The holding-down bolts for the lids are T-shaped, let into teak battens screwed to the side of the box. A broken bolt can thus be readily exchanged without having to mutilate the box. The metal used for the bolts is brass washed with lead, and the nuts are lead covered, so that the whole is protected from the effects of acid fumes.

Adjoining cells are connected by cables fitted with lead sockets, which are attached to pillars projecting through the lids from the section bars. Where the pillars pass through the lids they are sheathed in indiarubber gaskets. The pillars are of a patent type, consisting of antimonial lead below the acid level, finishing in pure lead above the acid level. The positive lug is pointed to be readily distinguished from the negative lug, which is flat.

Since the advent of the metal filament lamp, it is practicable to employ batteries on sailing yachts and motor launches to run a few lights for periods up to a month without recharging. A special light type of battery known as the "Exide" has been developed by the Chloride Company for this purpose, and is arranged in a conveniently portable form in a crate so that the battery can be easily taken ashore for recharging when necessary.

Searchlight Projectors for Marine Purposes.

BY E. A. HOLMES.

(Of Messrs. Siemens Bros. Dynamo Works, Ltd.)

Summary.—The searchlight projector has now become a necessity alike in the Royal Navy and in the mercantile marine. Parabolic mirrors for projectors are usually of glass, silvered at the back, the precision of manufacture depending upon the quality of the result desired. This accuracy can be determined by two simple tests. The carbons are usually horizontal and may be adjusted by hand, or will burn automatically. In conclusion, some special accessories are described.

The electric searchlight or projector may be said to have been brought into existence to meet naval requirements when the spar torpedo, rigged on the bows of a fast steam launch was brought out. Some means of defending a warship from this form of attack was necessary, and an electric arc lamp, enclosed in a casing fitted with a Fresnel lens and mounted on a suitable support for directing the beam of light in any direction, was the answer to this new development.

The invention of the Whitehead torpedo discharged from a torpedo boat at a distance necessitated a more powerful apparatus, and the Fresnel lens gave place to the glass mirror backed with a coating of silver. This was a great improvement and remains the type of projector in use at the present moment. Improvements in detail, especially the perfecting of the mirror and lamp, have brought the searchlight to its present high efficiency.

The searchlight is extensively used in the mercantile marine. It is now usual for all first-class passenger ships to carry one as part of its permanent equipment, especially those ships that make use of the Suez Canal, the searchlight making it possible for them to continue their journey after dark, and thereby reducing the length of the voyage, and at the same time increasing the tonnage capacity of the canal. There are many other purposes for which they can be used with advantage. River steamers find them very useful, especially those navigating the large inland waterways of North and South America and the Continent of Africa. Steam yachts in which current is available are hardly considered complete without at least one searchlight.

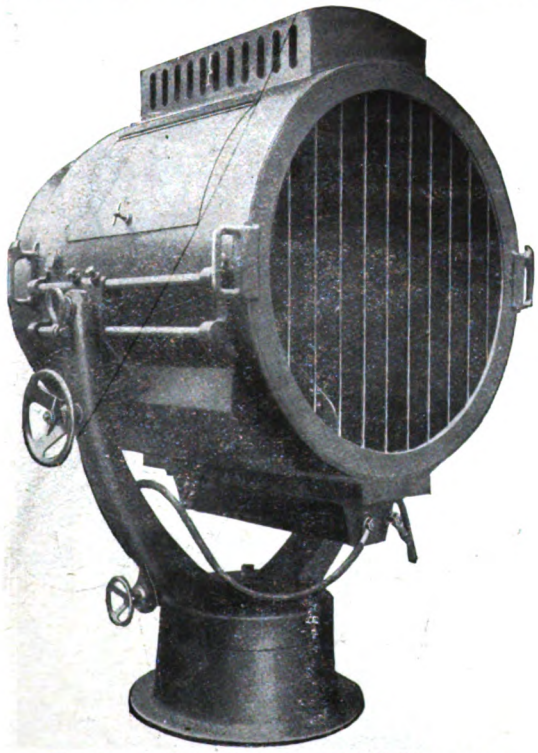

FIG. 1.—A 24 IN. SIEMENS "M.P." PROJECTOR.

The searchlight fitted with a signalling shutter forms a valuable means of transmitting messages to distances within range of the beam of light; by using the Morse code this can be rapidly dealt with both by day and night.

As the efficiency of the projector depends so much on the mirror, great attention has to be paid to this part of the apparatus so as to obtain the best results. At the present moment, for general purposes, the reflector of glass, parabolic in form and backed with a deposit of silver, holds the premier position. The glass mirrors have been found to withstand the deteriorating effects of the gases given off by the arc whilst burning better than any metallic mirrors tested up to the present, and at the same time they are not injured by the frequent cleaning found necessary to keep them free from dust, &c.

Modern high-grade parabolic mirrors are optically perfect; their manufacture requires great skill and care in carrying out the several operations of grinding, annealing, polishing, &c. Both surfaces of the mirror are worked to a high degree of accuracy. A coating of silver is deposited on the convex side, which is, in turn, protected by means of a composition capable of withstanding the high temperature it is subjected to.

The Mangin mirror is a concavo-convex lens; the back convex surface (on which silver is deposited, forming the reflector) is ground to a larger radius than the front one, giving a much greater thickness to the edge than the centre of the mirror. The radii of the two surfaces are selected of such a length as to correct the mirror for spherical aberration. Mirrors of the Mangin type are still made, but, owing to the varying thickness of the glass, they are more liable to fracture when subjected to great difference of temperature, and in cases where minimum weight is desired they are not suitable, the weight being about three times greater than a parabolic glass one of the same diameter.

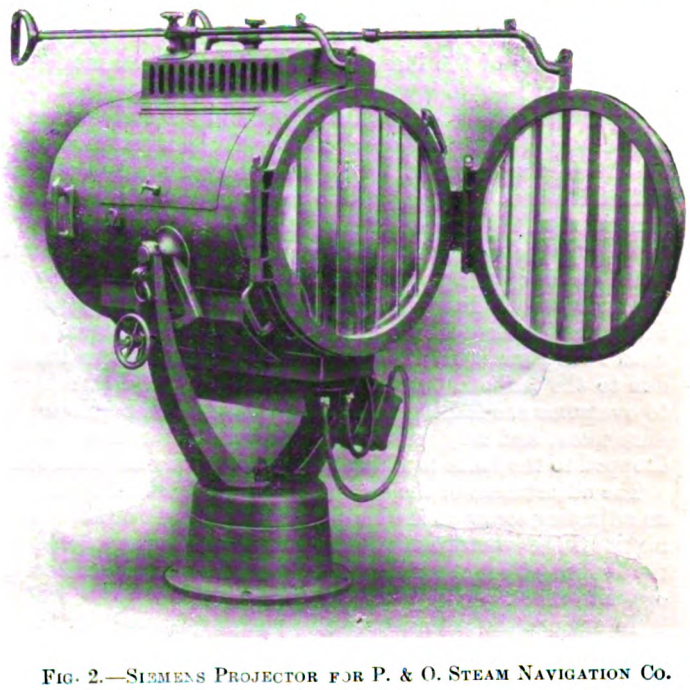

FIG. 2.—SIEMENS PROJECTOR FOR P. & O. STEAM NAVIGATION CO.

A perfect mirror should theoretically throw a parallel beam if the source of light is a point; this is never the case, the crater of the positive carbon having a diameter the ratio of which to the focal length of the mirror gives an angle of dispersion to the beam of light between $2\frac{1}{4}$ deg. and 3 deg. In practice this angle of dispersion is necessary for giving an illuminated field large enough to distinguish objects at a distance. It will be readily understood that, were it possible to throw a parallel beam of light to a great distance, it would

Digitized by Google

have a diameter no larger than the reflecting mirror, and would appear as a small bright spot, which would be useless.

The accuracy of the form of a mirror can be determined by two simple tests. The first is to discover whether the curvature is regular from the centre to the edge. This can readily be examined by placing the mirror in front of a screen with a white ground on which are ruled black lines across one another, dividing the whole surface into squares, measuring about 2 in. each way. In the centre of the screen a hole is cut, through which the lines can be viewed reflected on the surface of the mirror. These lines may appear straight or curved, depending on the distance of the mirror from the screen, but any waviness or blurring of the lines denotes irregularities of the surface. The second test is to prove the accuracy of the parabolic form. The rays from a distant source should meet at a point if it has been corrected for the slight deviation to the rays caused by the thickness of the glass. Screens with annular openings of varying diameters are placed separately in front of the mirror and the focal length of the point of light measured carefully in each case; any variation given by the screens denotes inequality of the curvature.

The horizontal lamp has almost driven the inclined type out of use in recent years, it being acknowledged to have several advantages over the latter. The lamp takes its name from the position of the carbons, whose axes coincide with the beam of light which is horizontal in its normal position.

The horizontal lamp is usually designed to burn automatically or by hand at will, and every part should be made with a view to simplicity and durability, mica insulation being made use of wherever possible. The whole of the mechanism should be readily accessible by means of dust-proof covers. All small screws should be secured so that there is no possibility of losing them.

The feeding of the lamp with automatic shunt mechanism is as follows:—

When the current is switched on and the carbons are not touching, the only path open is through the shunt-wound coil of the feeding magnet. This coil, therefore, has the full potential across it, causing it to feed the carbons together at a rapid rate. The moment they touch current flows through them, and the arc striking coil in series with the carbons energises an electromagnet and strikes the arc by drawing the negative carbon from the positive, this immediately causing the current to drop in the shunt coil, which then ceases feeding until such time when the volts have increased across the arc, due to the carbons burning away, causing the electromagnet to overcome the feeding spring. The lamp then begins to feed once more, and only stops when the volts across the arc have dropped to the value to which the feeding spring has been set.

The adjustment of the spring is usually obtained by turning an adjusting screw on the lamp body to the right or left. Turning it in the one direction strengthens the spring, increasing the length of arc; turning it in the other direction has the opposite effect.

To cut out the automatic feeding mechanism a lever, placed in an accessible position, is provided, which, when thrown over to the position marked "Hand," breaks the circuit of the shunt coil and at the same time throws the feeding pawl out of gear, allowing the hand wheel to be rotated in either direction and moving the carbons to or from one another.

Dispersing lenses are employed for dispersing the rays in a horizontal direction. Two types are manufactured, one having a fixed angle of dispersion, which must be determined when ordering the lens, and can be ground for any angle up to 35 deg., the other fitted with a pair of lenses so designed that the beam of light can be dispersed at any angle at will, from a concentrated beam to an angle of 45 deg. maximum dispersion, by simply turning a handle which varies the distance between the two lenses.

Under certain circumstances in warfare, it is necessary to throw a beam of light suddenly in any given direction without allowing the enemy to detect the presence of the projector before its use. As it is impossible to make the signalling shutter absolutely light-tight, the Iris shutter has been designed for this purpose. This is composed of a number of thin sheets of metal of crescent form mounted on the front of the projector in a frame in such a manner that by actuating a lever the beam of light can be absolutely shut off or exposed at will.

To obtain the best results with a projector the volts across the arc should be steady, and for this purpose high-grade carbons must be used. It is now usual to fit a voltmeter and ammeter on the projector, so that the attendant can note any falling off of regularity in the current supply and make the necessary adjustments from time to time. The shape and regularity in the burning of the arc should also be under constant supervision. High-class projectors are sometimes fitted with reflectors for throwing two views (at right angles to one another) of the carbon points on a ground glass screen, hand wheels for adjusting the carbons from outside the projector body being within easy reach.

In conclusion, attention is drawn to the great falling off in efficieny of the projector with the accumulation of dust. Both the mirror and front glass door must be kept scrupulously clean. The cloths and cleaning pads should be kept in a dust-proof box, and used for no other purpose.

Siemens Projectors.

The firm of Siemens was one of the first to take up the manufacture of searchlights. Large numbers have been supplied to the British Navy, and they have found a place in almost every foreign one also. They are manufacturers of a line of

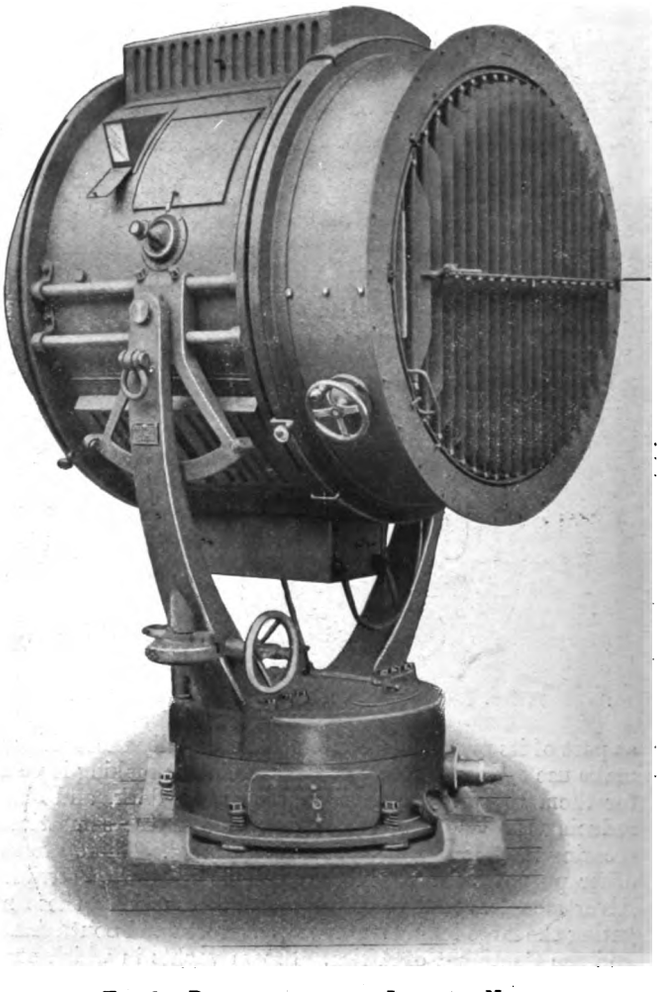

FIG. 1.—PROJECTOR FOR THE JAPANESE NAVY.

projectors fitted with mirrors ranging in size from 10 in. to 80 in. in diameter, and supplied with hand and automatic horizontal lamps suitable for burning with a current of 15 amperes in the smaller sizes up to 250 amperes in the largest.

The Siemens 24 in. "M.P." projector on a short pedestal is illustrated in the preceding article. The pedestal is fitted with adjustable trunnion, worm turning and geared tipping

FIG. 2.—TWIN PROJECTOR.

motions and automatic lamp. The pedestal can be increased in height to suit any special requirements.

The same article includes an illustration of one of a large number of projectors supplied to the P. & O. Steam Navigation

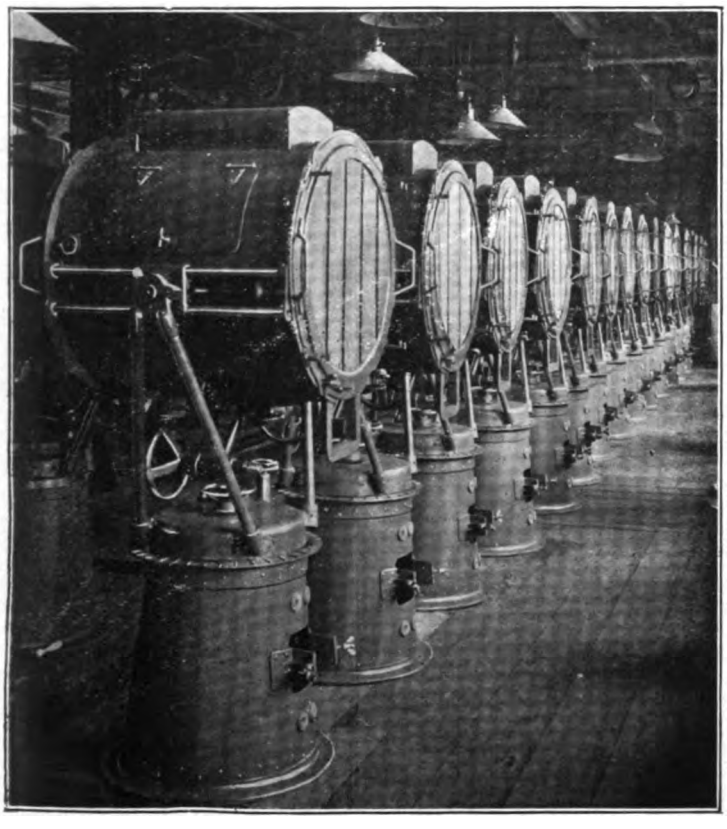

FIG. 3.—ROW OF 24 IN. PROJECTORS FOR BRITISH ADMIRALTY.

Co. These are of the ordinary "M.P." pattern, but fitted with two dispersers, one of which is ground to suit the special requirements necessary for navigating the Suez Canal—which is, that the beam of light shall be split into two rays to illuminate the buoys on either side of the canal and leave a zone of darkness directly ahead so as not to interfere with the navigation of ships coming in the opposite direction.

Fig. 1 is taken from a large order received from the Japanese Government for their Navy. The one illustrated is fitted with a 36 in. mirror, double disperser, Iris shutter and signalling shutter, arc viewer and carbon adjusters. A large number have also been delivered, similar in pattern, but arranged with electric motors for controlling the tipping and turning motions from a distance.

Fig. 2 represents a twin projector for use on warships; it consists of two projectors mounted on a common pedestal.

Fig. 3 shows a row of 24 in. projectors forming part of an order received from the British Admiralty.

We might add that Messrs. Siemens have not only made projectors for marine purposes, but large numbers have been supplied to the British War Office and Colonial Government for use in protecting the sea coast; and also a light design, varying in size from 15 in. to 36 in. diameter of mirror, for mounting on carriages for field use.

Crompton Projectors.

The subject of projectors is one hedged about with a definite amount of intelligible mystery. For it is not to our advantage, as a nation, to give away the details of the design of this

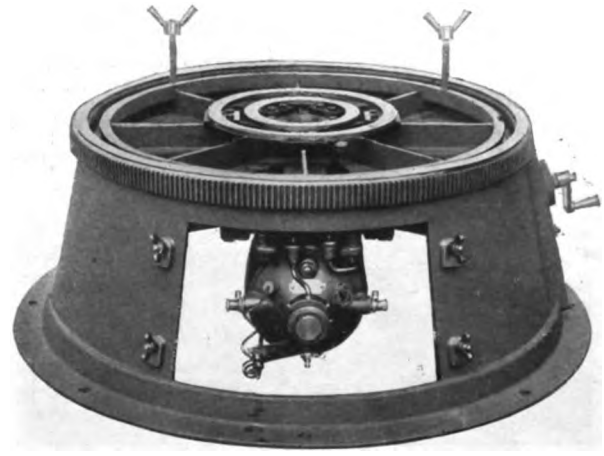

FIG. 1.—BASE OF ELECTRICALLY-CONTROLLED 36 IN. PROJECTOR.

plant, as on its secrecy depends much of the safety of both our coasts and ships.

Certain firms have paid special attention to the design of this class of plant, and among them are Messrs. Crompton & Co., of Chelmsford. It will, therefore, not be without interest to give some information about their projectors, though, for the reasons mentioned above, this cannot be done in any great detail.

The requirements for projectors are so varied that it is a matter of difficulty to standardise any particular forms, but in general the four sizes, 16 in., 20 in., 24 in. and 36 in. may be taken as typical.

Fig. 5 shows a 16 in. projector on a high base with slow motion in the vertical and horizontal plane with diverging lens and switch on the base of the piston. The latest pattern of these is fitted with a hand-wheel for training in a vertical plane, this handle being fitted with a throw-out clutch in order that the operator may work the projector quickly by hand in the vertical direction. There is also an observation glass fitted to the right of the barrel, by which the operator is enabled to see the condition of the arc burning when he is standing at the rear of the projector. Anyone who has worked a searchlight will readily appreciate this as an advantage. This

Digitized by Google

particular type of projector has, further, been fitted with two diverging lenses hinged to the front of the projector and used

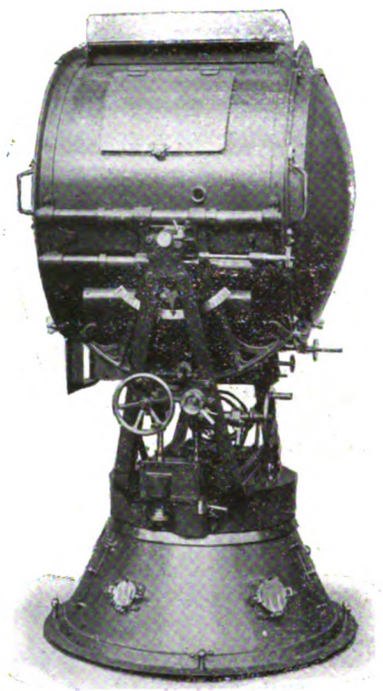

FIG. 2.—36 IN. CROMPTON PROJECTOR.

in conjunction with ships going through the Suez Canal. One diverging lens is an ordinary diverger which gives a diverging beam of 15 deg., the other is arranged so as to give a

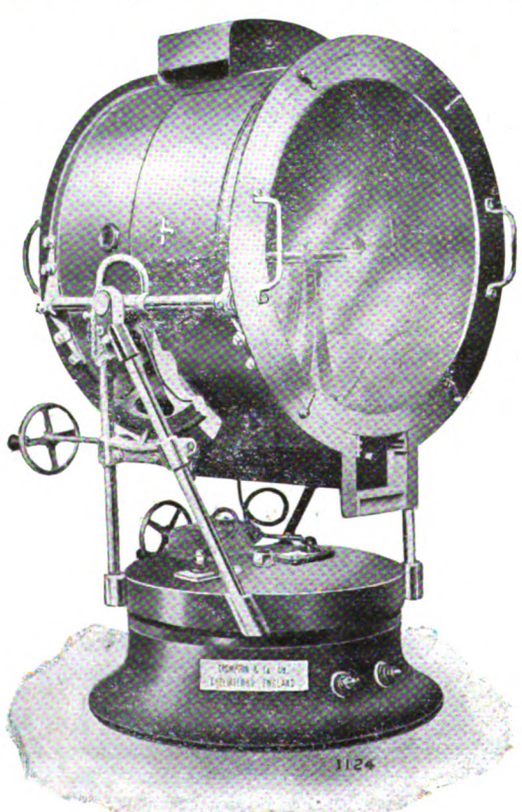

FIG. 3.—24 IN. CROMPTON PROJECTOR.

divergence of 15 deg. from the outside of the beam with a 5 deg. dark centre, thereby giving 5 deg. of light in the beam on either side of the dark centre.

The latest type of 20 in. projector, shown in Fig. 4, is fitted to such ships as torpedo boat destroyers and small ships in the

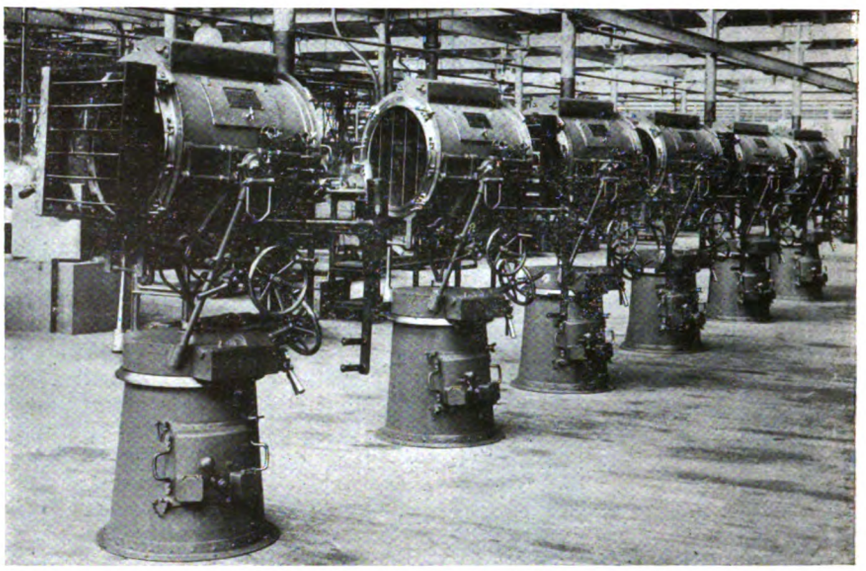

FIG. 4.—A SET OF 20 IN. PROJECTORS.

Navy. This projector has many special fittings, among which may be mentioned a shoulder-piece to enable the attendant to

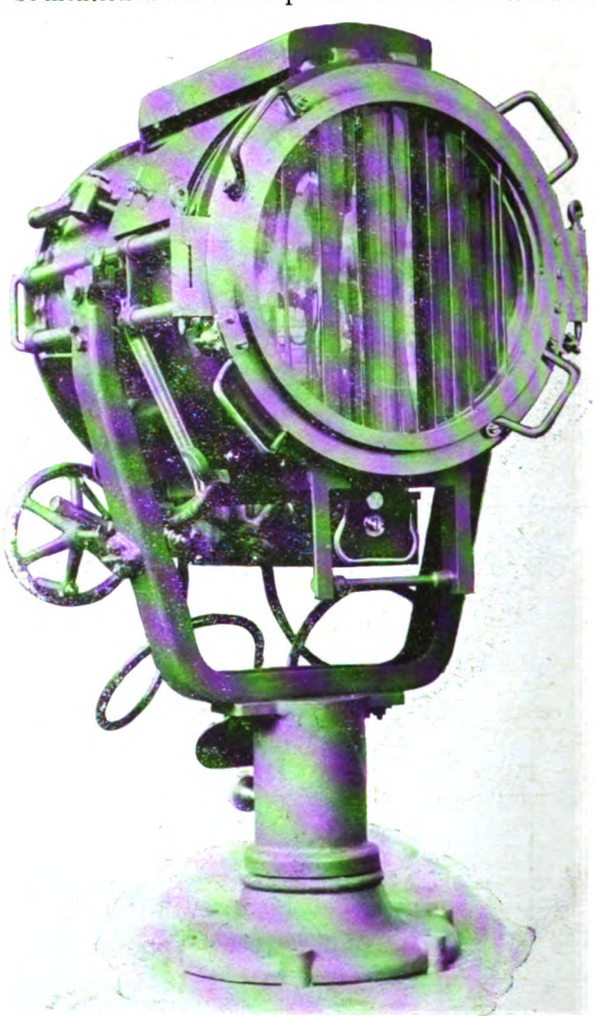

FIG. 5.—16 IN. CROMPTON PROJECTOR.

train the projector similar to the manner in which small light quick-firing guns are trained, the operator keeping his eye to a telescope which is fitted in the brackets shown at the side

Digitized by Google

of the barrel. The barrel is also fitted with running-out gear for balancing, which, as will be seen, is operated by the small milled head screws at the rear end of the barrel. This balancing indicating pointer being fitted on the turntable. A watertight double-pole switch and, in the latest pattern, an ammeter and voltmeter are provided fixed. Fig. 3 shows a 24 in. projector.

FIG. 6.—CROMPTON SEARCHLIGHTS IN USE DURING THE FLEET ILLUMINATION AT SOUTHEND-ON-SEA, 1909.
